gardens. It was a sudden marvel, but it is a standing wonder how a florist's garden can exist in the scorched black air of every-day Sheffield, and how flowers of such tender texture as the Auricula, Carnation, and Picotee can be grown in wonderful condition and beauty, and not only that, but also seeded, and led on. Without one sweet natural advantage in air, light, aspect, or soil have Ben Simonite and his father grown florist flowers for many years. It is a great struggle, only to be carried on with a complete armoury of simple, ingenious, and quaint contrivances for keeping every plant and bloom from deadly winds and poisoned smoke and the inky mixture of Sheffield rain.

These Sheffield Carnations and Picotees when known will be invaluable as illustrating and helping to fix the properties of these flowers: perhaps especially in Picotees. Pods are full of shapely petals that come down in their places and form a flower that barely needs a touch of dressing. Petals are of truly marvellous breadth, fine substance, kindly tempered and flaky, lying in beautiful form round the flower, and broad to the very centre of the pod. Another grand point attained is perfect smoothness on the edge as if "engine-turned." This great property of the Picotee is exquisitely tested and proved in the Sheffield light edges by the thin unbroken line of the colouring. It is the true and coveted "wire edge," the one perfect standard of marking in a light-edged Picotee. The wire edge is a finished excellence that cannot co-exist with the slightest roughness of petal edge, as every indentation there would eat into and break the "wire." Another high property now attained is perfect purity in the light and heavy reds. They have long had a flush or pinky tinge in the white ground of the petals, and no colour looks well upon an impure white.

Though dressing is legitimate in the Carnation and Picotee, yet it is no small virtue for a flower to "come down" without it, and to have few or no waste petals. We shall come to that, and indeed there are flowers that have; but at present growers of the older kinds must, if exhibitors, learn to be dressers. It should be reckoned as part of the necessary knowledge of the flower, and you certainly cannot make the best of your flowers, and they will not do themselves justice without it.

There is no trickery in fair dressing. It is much as simple and reasonable as brushing your own hair. You certainly cannot make the best of yourself without that dressing. Carnation petals either in getting the wrong way out of their green bed, or in being disarranged by the wind, get laid one upon another and lumped together. Dressing is to bring them each to light, and arrange them so that each may show its form and marking. The flowers are placed on cards to bring into sight their full circumference. Petals self-coloured and of malformations, known as "strap" and "finger" petals, may be drawn out, but no correct petals may be inserted. They could be, and even a new pod can be put upon a flower in place of a split one. Perhaps after these dark revelations I had better say I do not myself know how it is done, but it has been. It must be a delicate feat, almost as wonder-

ful as an attempt would be to put a wooden head upon a pair of human shoulders that had their proper "pod" split!

The question is put to me what the rule signifies at the National that a "mutilated" flower is disqualified. I cannot say much for the word here, except as an accepted technicality; but I know very well what it means. It means that though you may dress your Carnations and Picotees and pull anything bad out of them, you may not gum anything good into or upon them.—F. D. HOKNER, *Kirkby Malzeard, Ripon.*

### ESTIMATE OF STRAWBERRIES.

"C. P. P." (page 150) requests of the readers of our Journal their experience with regard to new Strawberries raised by Dr. Roden and Dr. Nicaise. Of the former we have Enochantress, Sir John Falstaff, Early Crimson Pine, and the Countess, all first-rate sorts, which cannot fail to give general satisfaction when more widely known. For my part they stand on the top of a choice collection. Of Dr. Nicaise's last seedlings we have Maria Nicaise, Auguste Nicaise, Berthe Montjoie, Duc de Magenta and Mad. Nicaise, which I consider the cream of the whole lot; they are all very large, handsome, and of fine flavour, besides being of healthy vigorous growth and great fertility.

Comte de Zahn (in Mrs. Nicholson's catalogue Comte de Zane) ought to be Comte de Flandres, an old Belgian sort; it is indeed an enormous bearer, but the plant rather too tender with ranky foliage to ripen its mass of fruit to the last. The quality is but poor and the fruit very soft, for which reason I discarded it many years ago.

During the past season we have seen of what little use it is to grow soft Strawberries, such as Marguerite, Brown's Wonder, and a host of others, which when nearly ripe were but a mass of decayed matter; whilst La Constante, Sir Joseph Paxton, Unser Fritz, Cockseomb, Sir John Falstaff, Sabreur, the Countess, Duke of Edinburgh, Souvenir de Kieff, and Dr. Hogg endured a four-days drenching rain in July quite unhurt.

Princess of Wales (Knight) is very early and good, but I find it in some seasons a bad settler.

La Grosse Sucrée (De Jonghe) is all what Mr. W. Leval says of it, page 182. In the Royal Gardens at Frogmore it is likewise much prized. I have had it in perfection in both light sandy and strong loamy soil.—FERDINAND GLOEDE, *Eppendorf, Hamburg.*

### PLANTS FOR CUT FLOWERS AND SPRAYS.

No. 1.

COLLECTIONS of plants have long been on the wane, though in some large establishments, and even in some of moderate pretensions, collections of some tribes of plants are aimed at, but in many instances, and I may say a majority, selections and not collections are the order of the day. It may be that where collections are aimed at many plants of no great attractiveness either in foliage or flower must be included; and as, from the rapidity of introductions from abroad and the no less rapid multiplication of varieties at home, these would occupy more space and entail greater cost than can be allotted to and expended upon them, selection becomes a matter of necessity rather than choice.

In the cultivation of plants some are given to a great expenditure of means, and bestow care upon the curiously beautiful, and so grow Orchids and Pitcher-plants and other curiosities; others delight in elegant, graceful, finely-divided foliage plants, and so cultivate Ferns. Some like stately forms, combining majesty with elegance and grace, and these grow Palms; others see most beauty in form and colour, beauty of outline and distinct markings, these cultivate florist flowers; and there are others, a growing majority, who set most value upon that which is chaste, pure, delicate, bright, fine in form, profuse in bloom, persistent also on the plant as well as enduring in a cut state, and if fragrance be added to these qualities, are the gems most sought after by proprietors of gardens of all grades.

Even the cottager with not a yard of land outside that he can call his own, garnishes his windows with plants, and though showy plants may be present in greater number, place is found for a representative of those emitting perfume. Now, this taste is by far the most prevalent of all others in the liking for flowers; and though some may yet linger over hobbies, or be led captive by the rare, curious, stately, or majestic forms of vegetable life, there are those, and it is difficult, and I think

wrong not to say all, have such a liking for flowers as to grow or have grown for them, the purest, brightest, and sweetest. The most profuse and continuous-flowering, the most beautiful in form or colour, whether of flower or foliage, are selected and grown in gardens, and by artificial means to supply a want of flowers and sprays for cutting, for the taste is so strong that nothing short of the presence of them in the places where leisure is passed, or friends entertained, will satisfy.

The demand for cut flowers and sprays of elegant, graceful, and finely divided parts (or with distinct markings), of foliage for a setting and relief of the bright hues of the flowers is ever increasing. This increase in the demand for cut flowers and plants for decoration has doubled itself within the past ten years, and quadrupled itself during the past thirty. This rapid development of the taste prompting the demand, we can only conclude, has been fostered and given by the increased establishment of horticultural societies in most towns and very many villages. Though we must admit the claims of horticultural societies to the foremost place in advancing the taste for horticulture, and its adoption as a relaxation from life's turmoil by the masses, much must be claimed for the press in giving instructions in culture, and in bringing before the distant as well as near the new introductions which are added to horticultural wealth by the enterprise of collector or the skill of hybridists.

I will proceed to notice some plants which are suitable for affording sprays and cut flowers in a future communication.—G. ASKEW.

### OLLA PODRIDA—A CONTINENTAL TOUR.—No. 8.

WE did not stay long enough in Turin to inspect all the public gardens and squares there, as we were anxious to press on to Venice, staying for two nights in Milan on our way. Milan is a very different town to Turin, for whereas in Turin all the streets, as I said in my last, run at right angles to each other in a way which would thoroughly suit the American taste (in fact a Yankee, who was a fellow-voyager with us from Aix-les-Bains to Turin, said he felt quite at home there). Milan, on the contrary, seems to be of much older date, and hardly any of the streets are either parallel or at right angles to each other. The whole town is surrounded with a line of fortifications or ramparts, with twelve gates. The line of fortifications is planted all the way with a double row of trees, either Limes, Horse Chestnuts, or Plane trees, with a broad road or drive running through them. This forms a pleasant and a shady drive, which is a favourite place of resort for the Milanese; though here, too, as in other towns, fashion reigns supreme, and only a short part of this road forms the fashionable drive—a piece just outside the public gardens called the Bastione de Porta Venezia. This forms the Venetian Rotten Row, or Route de Roi; though why so small a part of this drive should be used it is difficult to say, except that it is rather wider and more raised than the rest. It is, however, far too short, as it is not much more than a quarter of a mile long, and carriages have perpetually to turn, as the only piece which is used as the fashionable drive and promenade is between the Porto Venezia and the Porto Principe Umberto which leads to the Central Railway station. The Milanese, however, do not care about taking many turns on the Bastione, as the line of carriages soon comes to a standstill outside the public garden near to the bridge which leads to the Café Restaurant. The ground on which the Café Restaurant—a sort of Rotunda Kiosk—is built is raised on the same level as the Bastione de Porta Venezia, and crosses over one of the principal roads or paths of the public garden by a bridge made of rough tufa blocks. All the sides of the mound or raised ground on which the Café stands is chiefly ornamented with rockwork principally formed of tufa, and all the pathways leading down to the ordinary garden level are also made to pass through rockwork. This is not well arranged, as a rule, for plants to grow in, and the Ferns do not seem to thrive, except in some aspects. The gardens are nicely laid out as far as the walks are concerned, and there is a stream of water passing through it in which aquatic plants grow freely, and there are a few ornamental wildfowl there which seem much at home; among which were some pelicans and swans.

What struck me much was the almost utter absence of flowering plants; the only bed I saw in flower was a bed of Monthly Roses, and the only bed of coloured foliage was one of purple Orach (Spinach). Some of the flowering shrubs were, however, very fine to compensate, especially the Mag-

nolias, which were just coming into flower, and fine bushes of *Deutzia crenata flore-pleno*, and of the large-flowering white *Syringa*, &c. Some of the Pines and Firs were doing well, as *Cupressus Lambertiana*, *Lawsoniana*, &c. The grass, as is so often the case in public gardens in hot countries, was utterly spoilt from not being cut; and there was less excuse for this, as there was plenty of water at hand to keep the grass fresh. There were a few nice plants of *Arundo donax variegata* just beginning to throw up new shoots alongside the watercourses, which promised in time to be very ornamental. On the whole, these public gardens, with their avenues of trees and shady walks, form a pleasant lounge for the people of Milan on a hot summer's evening; but it seemed to me a pity that a little more care and attention was not paid to them, and that too much was left to a naturally fine soil and climate. I should much like to see one of the quarters of the garden planted with subtropical plants, as *Cannas*, *Ricinus*, *Maize*, *Abutilon*, &c., mixed with some of our choicer flowering plants, as I think the climate and soil is such that nearly all the denizens of our stoves, as *Allamandas*, *Clerodendrons*, &c., would thrive there under proper treatment during the summer months.

The only other public garden we went to see at Milan was the *Orto Botanico*, at the back of the *Brera Gallery*. This is a closely walled-in space in the middle of the streets of the city, and which we found after taking a great number of turns along corridors, after leaving the *Brera Gallery*, with finger-posts pointing to the *Orto Botanico*. The Curator received us in very fluent Italian, much of which I fear was lost on us. He was very proud of a very fine specimen of Purple Beech, which certainly was the finest tree of its kind I had ever seen, the bole measuring 12 or 13 feet in circumference, and the stem straight. The head of the tree was tall, and the branches very regularly and symmetrically arranged. He assured us repeatedly it was the finest in any public garden, and that several curators from other botanical gardens had expressed their admiration of it. There was not very much else worthy of note except a very fine specimen of *Magnolia*, one of the finest to be seen anywhere. I forget the name of the species, but it was the glossy-leaved one, which is grown in many places of England against our walls. There was also a very good specimen of the *Paulownia imperialis*, with very fine broad leaves; and of the *Catalpa* and *Bignonia*. The garden on the whole was too confined and divided—as are many botanical gardens—into a number of small parallelogram beds, each filled with their different genera of plants, amongst which was a bed with different kinds of wild English *Geraniums*. I was also amused to see a number of our English-raised *Coleus* seedlings in the conservatory. I forgot to say that an attempt to grow a few of the Pine and Fir tribes had signally failed, one or two *Wellingtonias* eking out a miserable existence. On the whole I might say of Milan that while the avenues of trees were well cared for, and many of the flowering shrubs, especially the *Magnolias*, seemed to flourish, there was a great lack of flowers, I hardly saw any in shops or in windows; too much seems to be left to nature. While driving along the ramparts we overlooked several of the gardens at the back of some of the rows of houses, in which the Vines trained from tree to tree seemed most flourishing; but in these gardens we hardly saw a flower.—C. P. P.

### TAKING-UP AND STORING POTATOES.

In the *Journal* of August 26th "*YORKSHIREMAN*" gives some advice as to the pulling the haulm from Potatoes to prevent disease, but he leaves the matter in such an imperfect state that many might be induced to try the experiment and spoil the crop. He says, "It is a pretty well ascertained fact that if the haulm is pulled away from the rows soon enough—that is, before they are in any way affected by the murrain, the crop itself is safe." I take no objection to this statement, only that it ought to have been supplemented by another well-known fact—viz., that if the tops are pulled away from the Potatoes before the latter are ripe the tubers are rendered useless for culinary purposes. They are what housewives call "sad," and no amount of skilful cooking or boiling can render them fit for the table. Thus it will be seen that the experiment is a very critical one, and the chances of failure are great, so much so that I know many growers who have tried it say that they prefer to allow their crops to run the chances of the disease sooner than resort to haulm-pulling. "*YORKSHIREMAN*" tells us he has experimented considerably in the matter, and he would render a great service if he could favour your

readers with further particulars as to when, how, and at what stage of growth the haulms can be pulled away without affecting the flavour and value of the tubers.—BETA.

### WHY PRUNE SO MUCH?

I REMEMBER years ago when the question, in a well-known periodical, was asked, "Why shave?" produced in the public mind a wonderful sensation. I wish to produce a sensation by asking, Why prune so much?

Of late something has been said in our *Journal* about spurring Morello Cherry trees. From my own experience I am satisfied that none need hesitate about adopting the plan, for I have practised it in years gone by on standards, pyramids, bush, and wall trees, and, to say the truth, I never thought the subject worth naming. I, however, will not quarrel with those who cling to the young-wood system with its hundreds of nails and shreds in a full-grown and well-managed Morello Cherry tree.

Forty years ago, when under-gardener in a nobleman's establishment, when sent to work, no matter what the weather, I was expected to remain the time, and I have stood by the walls during winter when I have not known whether I had hands or none. I resolved then, if it fell to my lot to have men under me, that the curse of me poor man's child should rest on my head on that account, and I am thankful to say I have kept the resolve. I know, too, that a better state of things exists now, and with care very much of winter nailing can, and in many places is, dispensed with. For my own part I am satisfied with the spur, and for convenience sake I intend to follow on, but I do not mean to say that I shall not have young wood in my trees as well.

While on the subject of spurs I may say that I have tried to have Peaches and Nectarines partly on spurs, and if I had a sufficient number of trees I should not hesitate to give the plan a further trial, for I am quite satisfied with the partial result. A while ago, in company with one of our craft, I was advocating the spur, and while descending over a splendid Peach tree indoors (for my friend is well up in the fruit department), I put the question, How about spurring the Peach tree? "Why, man," said he, "I durst not attempt it." Having my eye on two or three splendid natural spurs likely to have eight or ten blooms on each, I pointed to them, and said, "Of course you will dispense with these, then." He confessed that he liked them too well for that.

Do we not sometimes err in following too fine a line in the matter of routine? If some of our scientific and practical friends would give us their experience on this matter it might be of service. I do not see why anyone should hold back any information or suggestion, for we are in need of a constant interchange of ideas, and I look on our *Journal* as a valuable medium for the conveyance of such to its readers.—ONWARD.

**MR. PEARSON'S GOLDEN QUEEN GRAPE.**—We hear that this is better than ever this season, though carrying a crop of eighteen bunches. It certainly has been well tried by the raiser. It bore five bunches as a pot Vine in 1872, thirteen in 1873 when it received a first-class certificate, fifteen in 1874 when it was again shown before the Fruit Committee, and now carries eighteen bunches, which are better even than those of last year. Mr. Pearson has offered a prize of £5 for the best single bunch to be shown in the autumn of 1877, and £2 and £1 for second and third prizes; the time to be fixed after consultation with the Fruit Committee of the Royal Horticultural Society.

### NEW EARLY AND LATE STRAWBERRIES.

No. 1.

I now supplement my former article of some two years ago, with further notes and illustrations of such seedling Strawberries as have seemed to me by extended observation to be worthy of a place in the *Journal*; and, thanks to the engraver's art, I am enabled to give faithful representations of the average sizes and most predominant forms of the respective fruits.

The season just past has, like that of 1873, been highly favourable to the growth and development of fine specimens of Strawberries in general, but I have been especially careful to avoid exaggeration, and to place before the artist such moderate examples of fruit as any amateur with ordinary care and attention to the necessary means of culture, and having a

fair Strawberry soil, may reproduce in abundance in his own garden.

I commenced my observations on Strawberry culture several years ago, by saying that we had already plenty of mid-season varieties, such as *Carolina Superba*, *British Queen*, *La Constante*, and some others which could not easily be excelled, and that it was chiefly in the direction of better early and late sorts that the efforts of the raiser of new fruits should be directed. My chief object, therefore, in this article is to place before the public the complete list of early Strawberries which I have been for some years past engaged in raising and perfecting, and also such late sorts as, in addition to those already figured in this Journal, I have as yet been able to pronounce an opinion upon.

The first in order of the early sorts is *Alpha* (fig. 42). The fruit of this seedling is large and large medium, some of the

before *Early Prolific*, and this year it commenced ripening June 4th, coming-in with *Duke of Edinburgh* and *Early Prolific*, and being shortly followed by *Hundredfold* and *Amy Robart*.

*Duke of Edinburgh* (fig. 43), is a fine large fruit partaking of the joint characters of *La Constante* and *British Queen*. Foliage dark green, and the habit of the plant quite distinct from all other sorts. The fruit is mostly obovate in shape, like the illustration, and very handsome. Colour darkish crimson; seeds numerous and decidedly prominent; flesh creamy white; flavour piquant, vinous, and excellent; calyx small for size of fruit. It is also one of the best early forcers, and only requires to be better known to be universally cultivated under glass in place of Keane's Seedling and other large-growing leafy sorts. This and the following variety were distributed some five years ago, but are now introduced here in order to make the batch of early sorts complete, and also to give the benefit of faithful illustrations for the guidance of those who may not yet possess them.

*Early Prolific* (fig. 44), is becoming too well known to need description, but not having been previously illustrated, it is introduced for that purpose. The plant is of elegant habit of growth, with bright green foliage, distinctly dentate. Fruit large, and large medium. The woodcut depicts a fair medium

Fig. 42.—Alpha.

Fig. 44.—Early Prolific.

fruits being larger, some smaller than the illustration, according to the soil, climate, and skill displayed in the treatment. Colour bright glossy red; seeds numerous and rather prominent; flesh solid, pinky red throughout, melting and juicy, with a delicious high flavour. Season decidedly early, coming in with *Black Prince*, but owing to its lighter colour ripens up quicker than that variety, and is far superior in size and flavour. It is also a good and early forcer. Like *Black Prince* the plant is of rather slender habit of growth during the first year, but it increases in strength and fertility and in the size of its fruit for several years, and should not, therefore, be too frequently renewed.

Fig. 45.—Early Crimson Pine.

size. In some soils it is decidedly larger. Colour bright glossy vermillion, becoming a little darker when very ripe; seeds slightly embedded; flesh white, firm, and juicy, with a delicious refreshing flavour peculiar to this variety alone. Like the *Duke of Edinburgh* it is decidedly early, and is fast becoming accepted by practical gardeners as the very best early forcing variety we possess. The above three sorts should not be frequently renewed. They should be planted in well-prepared ground and allowed to remain several years, every other plant being removed the second or third year if the plants become too crowded. The two latter are now going on here for the sixth year, and I have no intention to disturb them so long as they keep increasing in the size and quantity of their fruits. If originally well done, plenty of room and autumnal surface-manuring are the chief essentials to insure good crops of handsome fruit.

*Early Crimson Pine* (fig. 45). This variety was figured in the Journal some two years ago, and I cannot speak too highly in its favour. The woodcut at that time may have been thought by some persons an exaggeration for so early a fruit, but I am happy to say that my garden has teemed the last two years with still handsomer specimens, and this autumn I intend planting all vacant ground with it. The fruit began to colour this last season towards the end of May, and here and there large fruits were ripe on the 4th June. Fruit handsome bright crimson colour; seeds rather prominent; flesh dullish white and sometimes pink, very juicy, with a rich piquant Pine flavour. The fruit is much like *British Queen*, observes similar shapes as it ripens, and has an equally rich Pine flavour, but colours up better all over the fruit. It has the advantage also of coming-in some three weeks before that excellent variety. Re-introduced here to make the set complete.

*Hundredfold* (fig. 46), likewise ripens very early, and is very

Fig. 43.—Duke of Edinburgh.

The next five sorts so rapidly follow each other that it is difficult to establish a correct order of succession, which, as in the case of many other fruits, varies with the different seasons; but as a rule, *Duke of Edinburgh* and *Early Prolific* follow *Alpha*. *Early Crimson Pine*, however, began to ripen in 1874

good either for the dessert or for an early preserving kind on account of its fine colour and immense cropping qualities. The fruit is large medium, and large, of bright red colour, with thickly-seattered rather prominent seeds; flesh solid, pale red through, juicy, with a brisk refreshing flavour, when fully ripe having a trace of the Hautbois. The plant is of vigorous healthy habit and bears well at once, but the second

as we learn from several correspondents, all of whom agree that it is earlier than Hale's Early, which has so far proved our best early Peach.

### ALEXANDRA PALACE. GREAT INTERNATIONAL FRUIT SHOW.

SEPTEMBER 2ND.

ALTHOUGH this was both a great and good Show, we thought it scarcely commensurate with the efforts that had been made, with the amount offered in prizes, and with its imposing name. There is, however, a suspicion, if not something more, that neither flowers nor fruit will ever look so good as they really are in this lofty and highly embellished hall. The high colouring of the edifice, the almost tiring blue of the ceiling, the scarlet flags and the gilded monarchs, are not the fittest associations for showing to advantage the natural colours of the earth's products. In an edifice less ornate and unbroken by elaborate columns a collection of fruit such as this would have been more striking in its effect; the force of the picture was in a measure lost by the extensive and artistic frame.

It is not possible to give a full and satisfactory report of this Exhibition owing to the resuscitation of the almost obsolete system of exhibiting under numbers, and the delay necessarily caused in first attaching the names and subsequently the prize cards. When this work is not completed until after the admission of the public it is impossible to take due note of the collections. The time lost in attaching the awards was the cause of complaint on the part of exhibitors and spectators. A simple and more expeditious system is generally adopted at most great exhibitions.

The Exhibition was divided into eleven divisions and eighty classes, most of which were filled, although in some there was but little competition. First in the schedule, and first also in point of interest, were the collections of fruit. For sixteen sorts of fruits Mr. Coleman, gardener to Earl Somers, won with a highly-finished collection, consisting of Black Hamburgh, Muscat of Alexandria, Lady Downe's, and Waltham Seedling Grapes, all of which were fine, but the berries of the latter were slightly rusted; two Pines, two Melons, Golden Gem being especially noteworthy; Bellegarde Peaches, Elruge Nectarines, Kirke's and Jefferson's Plums, Williams's Bon Chrétien Pears, Morello Cherries, and Moorpark Apricots. The second award went to Mr. Wildsmith, gardener to Viscount Eversley, and the third to Mr. Goodacre, gardener to Lord Harrington. These were very superior collections. In the collections of twelve sorts excluding Pines some capital dishes were staged, the principal honours falling to Mr. Gough, Little Malvern Court; Mr. Rushmore, Tondring Hall, Stoke; and Mr. Irving, gardener to the Duke of Hamilton, in the order named. The collections from which both Pines and Grapes were excluded were also very good; Mr. Cox, gardener to Earl Beauchamp, winning with Peaches, Nectarines, Plums, Melons, Figs, Apples, Pears, Cherries, and Apricots, all of which were good. The second prize falling to Mr. Chard, gardener to Sir F. Bathurst.

PINES were not numerous in the classes, but an imposing contribution of twelve Smooth Cayennes from Mr. Wilson, gardener to Earl Fortescue, were especially worthy of notice; they were sixteen months from suckers, and averaged 6 lbs. each, and an extra prize was deservedly awarded. The other principal prizetakers were Mr. Jones, Windsor; Mr. Wilson, Mr. Plummer, Cannon Hill Park; Mr. Harris, Singleton Gardens; and Mr. Chamberlain.

GRAPES, especially the black kinds, were very good, many of the Muscats not being highly finished. For eight varieties, one bunch of each, Mr. Upjohn, Worsley Hall, was placed first, Messrs. Lane & Son second, and Mr. Sallon third. The sorts were Gros Colman, good in bunch, berry, and colour; Muscat of Alexandria, not quite ripe; Black Alicante, splendid; Black Hamburgh, Buckland Sweetwater, Lady Downe's, Tynningham Muscat, and Muscat Hamburgh. For four varieties Mr. Coleman and Mr. Bones were the only exhibitors, and stood in the order named. Mr. Coleman's fruit was very fine in all properties, but Waltham Cross was again slightly rusted; this is evidently a distinct and fine acquisition amongst late white Grapes. For the best three bunches of Black Hamburgh there were ten exhibitors, and Mr. Coleman was again to the front with grand bunches splendidly coloured and without spot or blemish, followed by Mr. Wildsmith with well-finished bunches, Mr. Allward, and Mr. Upjohn. For Muscat Hamburgs, which were generally not well coloured, Messrs. Lane & Son, Mr. Bloxham, and Mr. J. Lane stood in the order named. For Madresfield Court Mr. Cox won with fairly good examples, followed by Mr. Wattam. For Black Alicante Mr. Farrance and Mr. Edmonds stood in the order named; the first-prize bunches especially being admirable examples of culture. For Lady Downe's Mr. Coleman won with medium bunches, but fine, clear, jet black berries; he was followed by Mr. Eap and Mr. Wildsmith. For Muscat of Alexandria Messrs. Lane & Son won with immense bunches, but not highly finished berries,

Fig. 46.—Hundredfold.

Fig. 47.—Amy Robart.

and following years, as its name implies, it turns off an immense quantity of fruit.

*Amy Robart* (fig. 47). This is a delicious large medium and occasionally large fruit, having a flavour quite *sui generis*. Colour bright palish red; seed numerous and slightly depressed; flesh solid, pinky white, exceedingly melting and juicy, with a rich piquant flavour quite new. The plant is healthy and a good grower. It is an enormous bearer and early, coming in with Early Prolific and Duke of Edinburgh, and lasting during the greater part of the Strawberry season.

*Scarlet Pine* (fig. 48).—This is a great favourite and not easily beaten in the high quality of its fruit. It is unfortunately not a very large fruit, being chiefly medium and large medium, but when very well grown tolerably large. The woodcut presents a fair medium specimen. Colour a beautiful

Fig. 48.—Scarlet Pine.

darkish scarlet; flesh pinky white, solid, and juicy, with an exquisite high piquant flavour scarcely exceeded by any known variety. Seeds numerous and prominent, it therefore packs and travels to a distance better than most other sorts. It also stands wet weather better than almost any other variety. In season it forms a connecting link between the early and mid-season crops, and is altogether a most *recherché* sort for the dessert. The plant is a first-rate grower and very hardy. All the foregoing sorts are uniformly great bearers.—W. RODEN, M.A., M.D., Morningside, Kidderminster.

[Portraits of late varieties next week.—Eds.]

EARLY BEATRICE PEACH IN AMERICA.—This, says the "Gardener's Monthly," has fruited in various parts of the Union

followed by Mr. Edmonds and Mr. Akehurst. In the single-bunch classes the Black Hamburgs were excellent, as also were the Alicantes and Lady Downes, the Muscats lacking finish, and the solitary bunch of Golden Champion being only a moderate specimen of its kind. The chief prizewinners in this section were Messrs. Coleman, Wildsmith, Irving, Upjohn, Edmonds, and Messrs. Lane & Son.

In the classes for flavour the qualities in blacks stood—Black and Muscat Hamburgs, and Madresfield Court, the growers being Mr. Cox, Mr. Coleman, and Mr. Thomas, Whetstone; and in whites Mr. Wattam, Mr. Stevens, and Mr. Bones won with Duchess of Buccleuch, Muscat of Alexandria, and Canon Hall Muscat respectively. The entries were numerous, but the bunches were generally poor. For the heaviest black bunches Mr. Goodacre won with a 6½ lb. bunch of Black Hamburg with poor berries; and for whites Mr. Edmonds was first with Syrian weighing 5½ lbs. The classes both for weight and flavour were not satisfactory, the big bunches not being fit to place on any gentleman's table; and as to flavour there was a poor return for the prizes offered, and which, indeed, were hardly needed to elicit the well-proved fact that well-grown examples of the staple varieties are always good in quality.

For the 12-lb. baskets there was good competition of first-class produce, Mr. Coleman winning in blacks with Black Hamburg, followed by Mr. Akehurst and Mr. Thomas. For whites Mr. Bashford won with Muscat of Alexandria, followed by Mr. Akehurst and Messrs. H. Lane & Son. In Class C, for two bunches of specified varieties, there was but little competition, except in the Black Hamburg class. The fruit generally was not of superior merit, except the finish of Mr. Luckhurst's Muscats, which was very noticeable. The principal winners were Messrs. Luckhurst, Mackie, Heard, Crane, and Le Sueur.

Messrs. Lane & Son had capital examples of pot Vines heavily laden with fruit. Of the Grapes, of which about five hundred bunches were exhibited, the blacks, especially the Hamburgs and Alicantes, were splendid, but the whites were generally deficient in finish. The baskets were an admirable display, and the "large bunch" and "best flavour" classes closely approached failure.

The division for foreign exhibitors only, was not a success, except as regards the Pears, and of these good specimens were sent. The Pine classes were empty, and the majority of the Grapes were indifferent. Muscat "Bedre" was the best, and Gros Colman was fairly good, but it is clear that our foreign friends cannot teach us any good lessons in Grape-growing, yet the fruit was generally set up in good condition, while many of the English Grapes had been injured in packing and transit. Disfigurement in this respect was very noticeable. In this division some good collections of Apples were sent, but not equal to the best examples of home culture. The winners were in Grapes Mr. Le Sueur, and in Pears and Apples Mr. Bashford and Mr. Pluck.

In Division E, which embraced Peaches, Nectarines, Plums, Pears, Apples, and Figs, a really splendid spread of fruit resulted. In the classes for twelve and six Peaches upwards of thirty dishes were staged, the majority possessing great merit. For twelve fruits Mr. Coleman had the first award for Crawford's Early, fine in size and colour; Mr. Jones being second with Bellegarde, a model dish; Mr. Grant following with an excellent dish of Chancellor. For six fruits the first honours went to Mr. Cox with Violette Hâtive, followed by Mr. Wildsmith with Royal George, and Mr. Smith, Bentham Gardens, with Noblesse. A beautiful dish of Dr. Hogg was exhibited by Mr. Luckhurst. Nectarines were also an admirable display, twenty-two dishes being staged with scarcely an indifferent fruit in the entire collection. In the class for twelve fruits Mr. Coleman was placed first with fine and highly-coloured fruits of Pitmaston Orange, Mr. Luckhurst following with admirable examples of Lord Napier; and in the class for six Mr. McClure won with splendid fruit of Violette Hâtive, followed by Mr. Akehurst with Elruge.

Of Figs eight very fine dishes competed, the first and second awards falling to Mr. Chisholm and Mr. Chard, for Brunswicks. For Plums, twelve of any sort, there was a great display of nearly forty dishes, Mr. Stephens and Mr. Bridgeman winning with Green Gage and Jefferson's; Mr. Lane had also an extra award for Jefferson's. This was a very successful class, the whole of the fruit being of fine size and finish.

PEARS AND APPLES.—Of these there was an admirable exhibition. For twelve Pears, two of each, there were sixteen competitors; Mr. Jones, Mr. Bashford, and Mr. Pluck taking the honours with splendid examples of Beurré Clairgeon, General Todleben, Doyenné du Comice, Beurré Bachelier, Beurré d'Amanlis, &c. For six fruits of Jargonelle Mr. Palling, Mr. Goodacre, and Mr. Gough had the awards; for six of any other sort Mr. Upjohn was first with Fondante d'Automne, followed by Mr. Noorman, and Mr. Jones, with Williams's Bon Chrétien; and for six heaviest Pears Mr. Bashford won with Belle de Jersey, weighing 6½ lbs.

Apples were extensively exhibited, but several dishes were incorrectly named. For a collection of dessert kinds there were

sixteen competitors, Mr. Pluck, Messrs. G. & J. Lane and Mr. Holder standing in the order named, and for twelve ripe dessert kinds there were eleven entries, Mr. Webb winning. In the class for six sorts of baking Apples there was a grand display, twenty-six competing, Mr. Cocks and Mr. Pluck being the most successful. The finest sorts were Warner's King, Lord Suffield, Kentish Fillbasket, Alfriston, Dutch Codlin, Blenheim Pippin, and Reinet du Canada. For the six heaviest Apples Mr. Pluck won with London Pippins, weighing 4 lbs. 13 ozs., followed by Mr. Chisholm with Warner's King, weighing 4 lbs. 12½ ozs.

MELONS were generally small. In the Green-fleshed section twelve fruits were exhibited, the best being Golden Gem, Worcester Hybrid, and Golden Perfection, from Mr. Tyler, Bishop Stortford; Mr. Gough, and Mr. Chaff respectively. In the Scarlet-fleshed section eight fruits were staged, the best being Red's Mottled, Hero of Bath, and Scarlet Gem, from Mr. Ellis, George Warren; Mr. Wildsmith, and Mr. Ross, in the order named. Mr. Coleman was the most successful exhibitor of fruit, winning nine first and two second prizes; his produce, which was very superior, being secured by Messrs. Webber and Co., Covent Garden.

VEGETABLES.—These were exhibited in collections, which were fairly good, but more remarkable for size than for quality and superior finish. Cauliflowers were all overgrown. Celery was common, and Parsnips were 4 feet in length. Beans, Peas, Potatoes, Turnips, Carrots, Onions, and Tomatoes were in excellent condition. For sixteen varieties Mr. Cox, Madresfield, and Mr. Holder, Prestonbury, were equal firsts, followed by Mr. Turk and Mr. Rushmore. In the collection of six varieties the winners were Mr. Smith, Mr. Bloxham, and Mr. Crane. In Salads two attractive collections were exhibited by Mr. Smith, Bentham Gardens, and Mr. Holder, who received first and second awards respectively.

MISCELLANEOUS.—In this class were interesting contributions. Messrs. Deard & Co. had their hot-water apparatus; Mr. Voice, improved Cucumber frames; and Mr. Webb and Mr. Cocks seedling Apples, for which certificates of merit were awarded. Fruit-bearing Apple trees lifted from the ground, and exhibited in baskets, by Messrs. Paul & Son, Cheshunt, were a prominent feature. They comprised over fifty sorts, and the trees from 8 to 6 feet in height were heavily laden with fruit. Messrs. T. Rivers & Son also exhibited fruit trees in variety, and an extensive collection of fruits, including branches of Plums of extreme fruitfulness. Mr. William Paul had a great collection of fruits the resources of the Waltham Cross Nurseries. Mr. Webb, Reading, staged a very fine collection of Nuts in twenty-eight varieties. Mr. Solomon, gardener to D. Flooke, Esq., sent a gigantic Pumpkin, nearly 7 feet in circumference. Messrs. Brown, Stamford, exhibited splendid specimens of Peasegood's Nonsuch Apple, which somewhat resembles Cellini highly magnified. Mr. Yeates had metallic labels; Mr. Matthews, pottery, &c.; Messrs. Balderson & Knox, insect killers; Mr. Kaye, skeleton leaves; and Mr. Laxton, new double Pelargoniums Guiding Star, Illuminator, and Emily Laxton.

The Judges of the several classes were most painstaking in their duties, and their awards gave general satisfaction.

#### TABLE DECORATIONS.

It was wise to add to the grand schedule for fruit one for table decorations, for they are always interesting to a large number of people, and as no other flowers were exhibited they gave variety to the stages. I was anxious to see what would be the result in a new locality, whether the old exhibitors would appear on the scene and new ones be added to them. Both classes came forward, and if the results were not very striking as to novelty, neither was there anything very offensive to the taste. In all I could suggest improvements, although, perhaps, had I to do them myself I should miserably fail. There were four tables in the first class, which was described as a "table 10 feet 6 inches long by 5 feet wide, completely laid out for twelve persons, and so arranged as to show the best means of utilising fruit and flowers in its adornment." It was evident that one of the exhibitors could not have read this, for no one could imagine that a plate, a fish knife, and a large silver fork was all that was required for the use of a dinner table. The first prize was awarded to Mr. Soder, gardener to O. Hambury, Esq. This was arranged with three centrepieces; the centre one consisting of a base, middle tray, and long glass top. This was very elegantly and lightly arranged, the top with sprays of Celosia and Grass; the central tray with some charming trusses of a Cape Geranium, some bells of Agapanthus, and Adiantum; the base with blooms of Vallota purpurea and Eucharis amazonica intermixed with Adiantum. The side vases were similar without the central tray, the top filled with Cornflower and Grass: the Cornflower was rather jammed down into the glass and spoiled its lightness. The bases were arranged with Water Lily, Vallota, and Adiantum. The fruit was arranged in glass baskets, and the table fairly treated with glass, &c., although I think some ruby glasses would have been an improvement, as there was not overmuch colour in either flowers or fruit.

The second prize, awarded to Mr. G. B. Wood, Hornsey Rise, was a fairly arranged table, although the flower arrangement was somewhat heavy, the base of the central piece being filled with Gardenias and Geraniums. The fruit on this table was very good and well arranged, but altogether it was greatly inferior to the first prize. The third prize was awarded to Miss Money, Alexandra Palace. In this there was great heaviness; the central piece completely hid those sitting opposite to one another, the glass itself being heavy and also heavily crowded with flowers. The quantity of fruit was enormous. There were four dishes piled up of Plums, two enormous dishes of Grapes, Peaches, &c., at each end; and I can only imagine that the previous *menu* was so scanty that the guests were expected to make up in fruit.

In the class for three stands arranged with flowers for the dinner table there were some very good entries. The first prize was awarded to Mr. J. Hudson, Champion Hill. The central stand was composed of a Palm, with *Eucharis* and *Yucca* arranged round the base; the sides two March stands, with *Grasses*, *Agapanthus*, *Lapageria* and *Lapageria alba*, and *Anthurium Scherzerianum*. The second went to Mr. Soder for three stands, rather too tall, but very elegant; *Grasses* at the top, with *Salvia patens*. There was also a want of proportion between the size of the base and the length of the stands. The third was won by Mr. Chard, gardener to Sir F. Bathurst, with a set of three stands with glass cornucopias: it was pretty, but too finicking. An extra award was made to Mrs. Stuart, 84, Seven Sisters Road.

In the class for two pieces the first went to Mr. W. L. Buxter for two vases, dissimilar, but either of which would be much appreciated by anyone for their drawing room. They were most elegantly arranged with *Russelia juncea*, *Climber Fern*, *Bouvardias*, and the pretty *Forget-me-not* *Impatiens Elizabeth*. These were very tasteful and pretty vases. The second (Mr. J. S. Chard), were two similar vases with one central piece and three smaller ones at side; the flowers at the base were rather too large and heavy. The third (Mr. J. Hudson) were two dissimilar vases; one a glass basket, charmingly arranged *Roses*, and an upright vase arranged with *Tritonia* and *Oncidium flexuosum*, an admirable flower for such purposes. Extra awards were made to Miss McKenzie and Miss Hyder.

The bouquets call for no particular remark. With one or two exceptions they had the too-prevailing fault of lumpiness. The plant cases, in which Ferns were the plants used, were not numerous; the best was exhibited by Messrs. Dick Radcliffe and Co., who had the first award, followed by Messrs. Marshall and Co. and Mr. Sinclair. For wedding bouquets the awards went to Mr. Studd, Heaton Mersey, Miss Money, and Mr. Bonsey; and for three opera bouquets to Miss Money, Mr. Bonsey, and Mr. Sinclair in the order named.—D., Deal.

## CRYSTAL PALACE AUTUMN FRUIT SHOW.

SEPTEMBER 7TH.

This Exhibition was only of moderate extent, and the fruit, except in the hardy classes, was not of superior quality.

In the collections of fruit Mr. Bannerman, gardener to Lord Bagot, secured first honours with an admirable display, consisting of a splendid Queen Pine, large Trebbiano and Black Prince Grapes, a good Marquis of Ailsa Melon, handsome Barrington Peaches, capital Brown Turkey Figs, and Pitmaston Orange Nectarines. Mr. Goodacre, Elvaston Castle, had the second place with a good and well-ripened Cayenne Pine, Grapes in excellent condition, and a good Melon, but the Peaches and Nectarines were rather small. Mr. J. Lane, gardener to Major-General Pyche, Pyrge Park, Romford, had the third place with a very handsome Pine, a large Melon, and good Peaches, Nectarines, and Figs, the Grapes being the weak point in this collection. Mr. Pitts, gardener to Mrs. Mayo, Riverdale, Dorking, had the fourth award.

**PINES.**—These were not extensive, yet some very nice fruits were staged. For the best Queen Mr. Fillery, gardener to S. D. Sassoon, Esq., had the premier award for a plump well-coloured fruit. Mr. Plummer, gardener to B. Thornton, Esq., being placed second with a nice tapering fruit; Mr. Goodacre having the third award for a good but somewhat over-ripe fruit. For the best fruit of any other variety Mr. G. T. Miles, Wycombe Abbey, won with a good unnamed fruit weighing 5½ lbs., followed by Mr. Plummer with a capital Smooth Cayenne; and Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, for a medium-sized Charlotte Rothschild.

**GRAPES.**—These classes were characterised by useful table fruit of medium size. Messrs. Lane & Son were placed first for Black Hamburg with well-shouldered bunches, good in berry and colour; followed by Mr. Crane, The Gardens, Logeshill, Chislehurst, and Mr. Alexander, gardener to R. Burgess, Esq., Sutton, Surrey. There were seven competitors. For Muscat of Alexandria Messrs. Lane & Son were again pre-eminent with large bunches which had done duty in "another place;" Mr. Clarke, gardener to J. Raines, Esq., Nightingale Lane, Clapham Common, having the second award for nice shapely bunches

Mr. Ansell, Castletower, Wimbledon Park, being placed third with larger bunches, but the fruit was not fully ripe. For three bunches of any white variety except Muscat of Alexandria Messrs. Lane & Son again won with good examples of Foster's White Seedling, followed in the order named by Mr. Hall with Buckland Sweetwater, and Mr. Alexander with Golden Champaign; the latter were fine in the berry, but were somewhat spotted. For black Grapes, Black Hamburgs excluded, Mr. Bannerman won with three medium-sized bunches of Gros Colman with splendid berries, black and spotless. Messrs. Lane and Son had the second place with Muscat Hamburg; Mr. Jones, gardener to E. Purser, Esq., Carshalton, being third with the same variety. For the "heaviest" bunch Mr. Crane won with a respectable bunch of Black Hamburg weighing 4 lbs. 9 ozs.; Mr. Goodacre being second with a bunch marked 5½ lbs., but the berries had not been thinned, and it was practically worthless; Mr. Taylor, gardener to S. Johnstone, Esq., Hampstead Heath, having the third prize. This class was disappointing.

**PEACHES.**—Of these a very fine display was staged by thirty-eight competitors, Mr. Bannerman winning with a dish of Barrington, splendid in size and colour; Mr. Douglas being second with a handsome dish of Exquisite, having a decided Apricot tinge; Mr. Harris, gardener to C. L. Norman, Esq., Oakley, Kent, having the third place with a dish of Royal George. Extra second prizes were awarded to Mr. Allen, gardener to S. Owens, Esq., Woodlands, Beckenham, for a beautiful dish of Princess of Wales, nearly white; Mr. Ansell with Gros Mignonne; and Mr. Harper, The Elms, Epsom.

**NECTARINES.**—This was also a fine display, comprising twenty-six dishes. Mr. Tillery, Welbeck, had the premier place with the best dish of Victoria which has this year been exhibited. The fruit were in perfect colour, and upwards of 2½ inches in diameter; Mr. Jordan, gardener to J. Bunstead, Esq., Wimbledon, had the second place with Violette Hâtive; Mr. Moorman, gardener to the Misses Christie, Kingston-on-Thames, being third with Elruge. Extra second prizes were awarded to Mr. Holliday, gardener to J. Morris, Esq., Castle Hill, Bletchingley, with Rivers' Pine Apple; and Mr. Corp, gardener to S. A. Steel, Esq., Littlecot, Streatham Common, with Elruge.

**FIGS.**—In this class there were five competitors, Mr. Chisholm, gardener to R. C. Taylor, Esq., Boughton Place, Maidstone, winning with very fine Brunsbicks; Mr. Neighbour, gardener to G. Wythes, Esq., Bickley, being second; and Mr. Bannerman third with Brown Turkeys.

**CHERRIES.**—Of this seven dishes competed, and the fruit generally was very good. Mr. Sage, Ashridge Gardens, won with splendid Morellos, followed by Mr. Miles and Mr. Chisholm respectively.

**PLUMS.**—This was a remarkably fine display, there being no less than thirty-eight competitors with three dishes each, taxing to the utmost the discriminatory powers of the Judges. They eventually decided in favour of Mr. Sage, who had Jefferson's and Washingtons in perfect condition, and a fine dish of Kirke's. Mr. Holder, gardener to W. Balston, Esq., Springfield, Maidstone, had the second place with Washington, Jefferson's, and Green Gage; Mr. Jones, Carshalton, being third with Washington, Jefferson's, and Kirke's; and Mr. Douglas fourth with Transparent Gage, Bryanston Gage, and Jefferson's. A finer display of Plums than the above has seldom been seen.

**MELONS.**—Of these twenty-six nice table fruits were staged. In the Green-fleshed section Mr. Harris, Oakley, won with an attractive and finely-flavoured fruit of Beechwood; Mr. Webb, Calcut, being placed second; and Mr. Gadd, Castle Garden, Dorking, third with Golden Perfection. In the Scarlet-fleshed section Mr. Pitts, Riverdale, won with a handsomely-netted fruit of Read's, followed by Mr. Kneller, Malshanger Park, with Victory of Bath, and Mr. Harper with Turner's Scarlet Gem. An extra first prize was given to Mr. Sage, Ashridge, for a highly-flavoured fruit of Colston Basset, white flesh.

**PEARS.**—For three dishes of nine fruits each a very fine display was made by twenty-four competitors, the fruit generally being of very great merit. Mr. Neighbour won with a grand dish of Beurré d'Amanlis, highly-coloured Louise Bonne of Jersey, and splendid Williams's Bon Chrétien; Mr. Sage, Ashridge, following with Williams's Bon Chrétien, Jargonelle, and a splendid dish of Fondante d'Automne; Mr. Longman having the third award with Williams's Bon Chrétien, Louise Bonne of Jersey, and Gratiell. In single dishes for the best-flavoured Pears Mr. Moorman, Mr. Longman, and Mr. Holder stood in the order named, each with Williams's Bon Chrétien.

**APPLES.**—Here was the finest feature of the Exhibition, many grand dishes being staged. For four dishes of nine fruits each Mr. Murrell, gardener to A. R. Allerton, Esq., Prittlewell, Essex, won with noble dishes of Cox's Pomona, Beauty of Waltham, Alexander, and Lord Suffield. Mr. J. R. Swinerton, Swanley, Kent, had the second award with Hawthornden, immense fruit, "Counsellors," Early Marie, and Lord Suffield; and Mr. Haycock, Barham Court, the third place, with Reinette du Canada very fine, Warner's King, Lord Suffield, and Alexander. As

extra award was made to Mr. Jones, Marshaton. There were one hundred dishes of some of the finest fruit ever exhibited. In the Dessert class of four dishes each about the same number competed. Mr. Webb, Calcot, won with Red Astrachan, Red Quarrenden, Early Julien, and Cox's Orange Pippin; Mr. Holder, Springfield, being second with "Jefferson" (Duchess of Oldenburgh), Kerry Pippin, Red Quarrenden, and Cox's Orange Pippin. Mr. J. R. Swinnerton had the third, and Mr. Longman the fourth awards.

In the Miscellaneous class prizes were awarded to Mr. Sleat and Mr. Goodacre for collections of hardy fruits; Mr. Webb for a collection of nuts; and Mr. Lakeman for vegetables; to Mr. Laing, Stanstead Park Nurseries, for a group of admirably-grown decorative plants; Mr. Coppin, Croydon, Roses; Mr. Turner, Dahlias; Messrs. Lane & Son, Grapes; Mr. Solomons, a gigantic Gourd; Mr. W. Paul, three hundred named varieties of Pears and Apples; and Mr. Waterer, Knapp Hill, Cupressus Lawsoniana erecta viridis, in handsome, dense, green columns.

base to tips. Meyerbeer and Norma were grand, and Orphée, Schiller, and Horace Vernet very good. Mr. Douglas exhibited his own seedlings in a great variety of colour, some of the scarlets being very bright.

For six spikes not in commerce, Mr. Kelway, Mr. Coppin, Croydon, and Mr. Douglas had the awards in the order named. In Messrs. Kelway's stand Lord Howard, salmon rose; Queen Mary, blush and purple; and Lord Petre, scarlet and crimson, are grand varieties; and Reginald Pole, Edward Courteney, and Simon Randel are also excellent. The Rev. H. H. Dombrain also exhibited a beautiful seedling resembling Norma. Certificates were awarded for these fine new varieties.

#### CLEVELAND HOUSE, CLAPHAM PARK.—No. 2.

THE RESIDENCE OF S. BALLI, ESQ.

Good gardening, in whatever place it is found, is always

Fig. 49.—PORTION OF CARPET BED AT CLEVELAND HOUSE.

1. *Sempervivum californicum* and *Sedum glaucum*.
2. *Alternanthera paronychioides*.

#### MODE OF PLANTING.

3. *Mesembryanthemum cordifolium* variegatum.
4. *Echeveria secunda glauca*.
5. *Alternanthera amœna*.

Certificates of merit were awarded to Mr. Turner, Slough, for the following Dahlias—Sairey Gamp, Mrs. Standish, Samuel Plimsoil, and Barmaid; and to Mr. Rawlings for Mr. Bennett.

Prizes were also offered for cottagers' Vegetables, of which a creditable display was made. The exhibition was well managed, the judging and awarding of the prizes being effected smoothly, speedily, promptly, and satisfactorily.

**GLADIOLI.**—Of these very fine spikes of the best varieties were exhibited. For thirty-six spikes Messrs. J. Kelway & Son had, as usual, the premier award. The blooms were massive, and the foliage was also good. In the rich colours the best were Saron, Phineus, Orbono, Meyerbeer, Minerva, Pitho, and Horace Vernet. Of the soft scarlets and salmons Pythis, Thunberg, Pionay, Umbro, Galemus, and Rev. H. H. Dombrain splendid. *Roses* and *Lilacs*: Syren, Orphée, Erilius, Petillus, and Culthar. *Lights*: Etandard, Shakespeare, Clymenus, and Eugène Scribe. In this class Mr. Douglas had the third prize with his own seedlings. In the class for twelve spikes the old rivals and old friends, Rev. H. H. Dombrain and Mr. Douglas, again met, Mr. Dombrain taking the lead with spikes expanded almost from

worthy of mention as a just recognition of the skill of a cultivator and as an incentive to others who are aiming at success. In many large establishments high-class gardening is to be seen, and not less true is it that superior examples of taste and skill are exercised in the grounds of villa residences. That this is so at Cleveland House is seen by the sketch which was given last week, where, however, the planting of bed a was inadvertently given under bed c, and vice versa. A further outline is appended of one of the finest and best-arranged borders of flowers to be found in the vicinity of the metropolis. The bank (fig. 50) is 60 yards in length by 8 feet in width, and forms the western boundary to a perfectly-kept lawn. In this border the Coleus in the circles and connecting links is in splendid condition. The bed (fig. 49) is noted as an effective example of carpet bedding, simple in design and easy to carry out, and which shows to advantage by the side of the intricate patterns which are now becoming fashionable. The chief effect of this bed consists in the *Alternantheras* and *Echeverias*, numbered

2, 4, and 5, being distinctly raised above the groundwork of *Mesembryanthemum* No. 3. The figures are on a scale of a quarter of an inch to the foot.

But, as I foreshadowed last week, it is not for the flower garden alone that this place is noteworthy, for there is an example of Vine-growing such as any man may be proud to show to his friends. The vinerias are 60 feet in length, and the canes are of the kind from which first prizes are made. The Vines were planted in June, 1874, and there are a few good Grapes on the nursing canes. It is not much to say, perhaps, that the wood of this season reaches the top of the house, and that it is ripening well, but when on measurement of the first half-dozen rods the circumference of each is found to be 2½ inches, and the joints are many of them within 8 inches apart, we find that bone and sinew preponderates over pulp, and that these Vines are as worthy of honourable mention as are the flower beds. These Vines are planted wholly inside in loam and bones. They are 2 feet apart, with an idea of resting the permanent canes and removing the nurses. But query, Messrs. Douglas, Luckhurst, Abbey, and other experienced cultivators—what will become of the roots of the nurses when their heads are cut away? Will they decay and engender fungus, and will this fungus spread to the living roots and endanger the welfare of the permanent Vines? Many besides Mr. Legg would be glad of a more satisfactory answer to that problem than is as yet authoritatively promulgated. Whether it is preferable to remove the superfluous Vines—the early slaves—or rest every alternate Vine annually, and let all remain to do a share of work? They are 2 feet apart. Think of that and of the fungus liability of dead roots, and give your verdict on the evidence which experience has afforded.

Mr. Legg's plan in producing these substantial and remarkably short-jointed canes has been to reverse the treatment which has so often produced a frothy long-jointed growth—viz., a high temperature in the early stages of the Vine's growth. These were started and grown-on as cool as possible, and not until they had attained substance was heat afforded, and then and now applied for ripening the wood. That is a rational and, as the Vines prove, a

1. *Roburula serrata glauca*.

13. *Centaurea compacta*.

FIG. 50.—FLOWER BORDER AT CLEVELAND HOUSE.

MODE OF PLANTING.

correct mode of treatment, and unless an accident occurs or a mistake is made something more will be heard of these fine Vines. To a majority of gardeners they are as interesting as the beds, and as well worthy a visit. Go and see them, and produce others like them. With that advice I leave the Vines for a "bit of plant-growing."

It is only fair to bear in mind that the plants here are only two years old, and yet these young plants have already won first prizes, not at mere local shows, but in such competition as is met with at the Regent's Park and Crystal Palace. Mr. Legg was also successful in carrying away two of the silver cups offered by Mr. Bull at the Show at South Kensington on May 12th. On inspecting these plants the visitor is struck with their quick growth, perfect health, and absolute cleanliness. They are grown in a spacious, well-heated, span-roofed house, supplemented by a brick pit, also well heated. Amongst the most striking plants are the Crotons. Their size, health, and colour, combined with age, are worthy of note. Croton Wismannii within two years from the cutting is upwards of 4 feet in diameter at the base, and was until recently 7 feet 6 inches in height, but is now shortened, and half-a-hundred cuttings are struck. C. Youngii is of the same age and size, with foliage 18 inches in length; C. undulatum and C. angustifolium are 4 feet through and 5 feet 6 inches in height at seventeen months from cuttings. Croton Johannis struck in December last is 4½ feet high, and fully 3 feet across, with leaves 1½ foot long, and beautifully coloured. These are handsomely furnished plants, with the foliage almost hiding the pots. C. majesticum, C. volutum, and C. spirale are also progressing with equal vigour. The above are a few of the most distinct Crotons, and should have a place in all collections of stove plants. In the same house is Dipladenia Brearleyana, unquestionably the finest of the Dipladenias, which had lately thirty-five blooms open at the same time; last year this plant was in a 3-inch pot. Alocasias, of the same age as the Crotons, are 4 feet through. Dieffenbachia Bausei has six fine stems 4 feet in height, and D. nobilis has a stem 8 inches in diameter with noble foliage; the top of this plant is being struck to form an exhibition plant for next year. In the same vigorous way are Dracenas, Allamandas, Bougainvilleas, &c., cultivated. Nepenthes are also laden with splendid pitchers; and the best of the Palms, including Cocco Weddelliana, Dæmonorops palembanensis, &c., are in admirable condition. Orchids are in the same order of luxuriance, a growth of Dendrobium moschatum, for instance, being 8 feet in length. Mr. Legg is also trying his hand at Heath culture with a healthy and promising collection.

The secret of Mr. Legg's success lies in unchecked supplies of water to the roots of his plants, also in the atmosphere, and a constant use of the sponge. He uses no insect-killers beyond soft soap, and this in the form of a preventive. It is impossible to find plants more clean and healthy than are these. Enough has been said to suggest that this small garden is worthy of a visit. It has been wholly remodelled within the space of two years, and is a laudable example of what can be accomplished by hard work and indomitable perseverance when combined with sound taste. In this little place Mr. Legg has won great success as a gardener, aided, however, not a little by the liberality of his employer, who enjoys his garden, and is willing that others should enjoy it also.

Owner and gardener are alike deserving thanks—the one for his kindness and the other for his skill in making that kindness a treat to the numerous visitors.—W.

### MIGNONETTE FOR SPRING DECORATION.

Few plants are more charming in the early months of spring than well-grown examples of this fragrant and popular flower. It is enjoyable at all times and under every form of culture, from the familiar bed in the summer garden to the fine pyramids of pot-culture which are produced by skilled adepts. But in no form is it more useful than when producing its dense healthy clusters in small pots as used by the decorators of Covent Garden for the adornment of window boxes and other modes of domestic ornamentation. Many are the attempts to produce these healthy pots, and it must be added many are the failures. These failures arise mainly from two causes—viz., growing the plants too closely, whereby they become drawn; or watering them too freely in the winter, when they become diseased and die off. Yet these pots of fragrance are easily producible if the following points of practice are strictly attended to.

The present is the best time to sow the seed for spring blooming, which should be in 48-pots well drained. The soil should consist of equal parts of rufy loam and well-rotted cow dung. Press the soil down rather firmly, and sow the seeds thinly on the surface, and cover them slightly with fine soil. Plunge the pots in a cold frame in ashes within 3 inches of the glass, placing a piece of slate under each pot to prevent the roots from penetrating through the pots. Water rather sparingly till the seed germinates. When the seedlings are large enough to handle thin them out to about twelve plants, after which only allow six to remain, keeping the strongest, after which they should have very little water. Give abundance of air night and day, and leave the lights off altogether on favourable occasions. Discontinue watering from the latter end of November till the latter end of February. This is where the secret of success consists, for if they are watered through the winter they become drawn, and the result is weakly plants and little bloom. Never mind the plants flagging a little, which sometimes they will do when the sun is powerful on them. In March they should be taken out of the plunging material, but still be kept in the frame close to the glass. They will now require liberal supplies of water, and must not be allowed to become dry. As growth progresses place a thin neat stick to each of the plants, which will admit the air amongst them and allow the lateral shoots to become strong. When in full growth give liberal supplies of liquid manure, especially after they have set their bloom.

The points to attend to are firm and rich soil, all the light and air possible during the winter months, little or no water for two months after the plants are fairly established, and abundant supplies when spring growth has fairly commenced. If the pots are plunged in ashes only a little covering on the glass is needful to preserve the plants from frost. By this mode of procedure are the compact and sturdy Covent Garden plants produced.—A. Y.

### DUNDEE HORTICULTURAL SOCIETY'S SHOW.

SINCE the enlarged views and enterprising spirit of the Committee culminated in the magnificent encampment in the Baxter Park in 1867, Dundee has taken the lead in Scottish horticultural shows. Superior displays of fruit may be seen at the Edinburgh and Glasgow Shows, but in flowers and vegetables Dundee stands ahead of these cities. Edinburgh offers £800 in prizes for its international show which comes off shortly; Dundee, in keeping with its enterprise, offers £1000 in prizes at its international, fixed to come off next year.

The Fête, extending over three days, came off in the High School grounds, in the very centre of the town, and was held partly in the High School itself and in three huge marquees. The central one, devoted to flowers, was 800 feet in length by 45 in width, 35 feet high in the centre and 8 feet at the sides. The marquee allotted to fruit measured 100 feet in length by 45 in width, and 35 feet high in the centre, while the marquee for vegetables was of the same dimensions. The entries were as follows—Pot plants, 245; cut flowers, 458; fruit, 450; vegetables, 494; dessert tables, 3. Total, 1640.

A brilliant assemblage of the rank and fashion of the town and neighbourhood were present on Thursday morning at the opening ceremony. The Earl of Airlie made a thoughtful and eloquent address, and formally declared the Exhibition opened. At the dinner in the Royal Hotel, where James Yeaman, Esq., M.P., the President, presided, addresses were delivered by the Earl of Airlie and Lord Kinnaird, Lord Lieutenant of Perthshire, and others. The Fête was formally closed on Saturday evening by Baillie Macdonald, one of the Vice-Presidents, in presence of a large gathering of the visitors.

Notwithstanding the very extensive and unhappy strike which has prevailed for the last six weeks with 12,000 hands idle, and from 80,000 to 40,000 people directly affected, and thousands of others materially affected, and those in work assisting in supporting those on strike, about 14,000 entered the gates, and the total income was about £550.

In flowers the Show was unexampled, and all the plants were in excellent condition. Among the most commanding was a pot of Lillium auratum grown by Mr. James Wilson, gardener to George A. Cox, Esq., Beechwood, consisting of four noble stems from 10 to 11 feet high, carrying a dozen beautiful flowers each. The challenge cup and £5 for best nine stove plants fell to Mr. McMillan, gardener to Joseph Grimond, Esq., Ochet Castle. The local nurserymen—viz., Messrs. Laird & Sinclair and Messrs. John Stewart & Sons, vied with each other in advancing the interests of the Show by sending collections of rare and beautiful plants for exhibition, and competing in every department for prizes with no small degree of success. Nurserymen from a distance were conspicuous by the prizes they gained. Among these were Messrs. Dickson & Co., Waterloo Place, Edinburgh;

Messrs. Robertson & Galloway, Ingram Street, Glasgow; Mr. McPherson, Polmuir, Aberdeen; Messrs. James Cocker & Son, Aberdeen.

Though there was a greater competition the fruit was inferior in quality to that shown last year. Councillor Moncur (ex-Bailie Moncur) was as usual very successful, his gardener, Mr. George Reid, winning no less than seven prizes in Grapes. Mr. Wm. Eddie, gardener to J. F. White, Esq., Castle Huntly, won the first prize for heaviest bunch of Grapes, his bunch weighing 8½ lbs.

Through the effects of the unpropitious spring the vegetables, though abundant, were decidedly inferior. The Parsley of last year would have swamped the greens of this year in bulk. Mr. Peter McArthur, gardener to John Leng, Esq., Kinbrae, Newport (managing proprietor and editor of *Dundee Advertiser*), gained the first prize for a basket of vegetables, ten varieties. Mr. McArthur won other five prizes in vegetables. Mr. D. Ross, gardener to Col. Macdonald, St. Martin's Abbey, who was first last year, came in second; Mr. Johnstone, Ashladie, third.

are figures of various animals cut in Box. Upon a level plot stands an Acanthus (now known as an *Acacia*), so pliant that I had almost said it was flowing; round it is a walk bounded by a dense evergreen hedge cut into different shapes. . . . . There are walks divided in some places by grass plots, in other places by Box trees cut into a thousand shapes, some of which are letters forming my name, and others the name of my gardener (*Topiarius*)."

Wherever they acquired territory the Romans introduced their arts and customs. Their gardening was no exception, and long after they had left our land their style of gardening remained. The earliest records of our extensive gardens show that part of their adornment was "*opere topiario*."

This practice long continued predominant, lingered on despite the preference for landscape gardening, and still lingers. Peacocks and other devices cut in Yew and Box are to be seen in the gardens of many old residences. Not very many years

Fig. 51.—TOPIARY WORK AT ELVASTON CASTLE.

The villagers of Baledganno in the Carse of Gowrie again distinguished themselves by carrying off no less than thirty prizes. The Show was in all respects a great success.

### TOPIARY WORK.

MANY modern mansions are dropped as it were in the middle of a park—the turf comes up to their walls. This we consider very bad taste. The gradation from the architecture to the unadorned ground should be gradual. A terrace, or succession of terraces, succeeded by a lawn studded with flower beds should intervene between the house and the park. We are so far from objecting to the terraces being bordered with mathematically-cut evergreen hedges, that we prefer them in many instances to stone balustrades. The taste for such hedges and other sixteenth-century garden forms is reviving; mazes, herbaceous borders, and old-fashioned flowers are in the ascendant.

With the Romans, one of our teachers in the fine arts, *Topiarius* was an ornamental gardener, and *Topia* the art of cutting shrubs into various forms, and forming other garden decorations. Pliny, in describing his Tuscan villa to his friend Apollinaris, tells that "Before the portico is a terrace adorned with various figures, and bounded by an edging of Box. Below this is a slightly descending gravel walk, on each side of which

since the motto of the order of the Garter—*Honi soit qui mal y pense*, was composed in Box in the garden of New College, Oxford. Such topiary work is still well exemplified in parts of the gardens of Elvaston Castle, as shown in the engraving we publish to-day.

London goes further than we can follow, for he advocates as appropriate to parterres in the *ancient* style figures formed of wirework, with evergreens trained over this, and gives as an illustration a man in a modern beaver hat with his arm round the waist of a female!

### EXTRACTS FROM DR. HOOKER'S REPORT ON THE ROYAL GARDENS AT KEW DURING 1874.

THE number of visitors to the Royal Gardens continues to increase annually, amounting to 669,436 in the past year, which is 15,556 in excess of 1873, the highest number previously known.

**BOTANIC GARDENS.**—In this department the hardy Fernery has been constructed and planted. It occupies a winding path 40 yards long, which has been made in continuation of that which runs along the front of the rockwork. About 560 species of Alpine plants were grown upon it last year. The Ferns are planted on both sides of the path amongst loose stones, which

form a low bank backed by evergreens. For the most part the old world species are on one side, and the new world ones on the other. An edging of Ivy along the path both tends to keep them cool and damp and to collect the dust raised by the feet of visitors, which in hot dry days, when many thousands are in the garden, is most prejudicial to the general health of such tender plants. About 150 species and varieties are planted out, many of them represented by both European and American specimens.

The collection of Liliums has been removed from the south end of the Herbaceous Ground, where they suffered from the intrusion of the roots of trees into soil prepared for them, to the west side of the Ivy collection on the other side of the wall bounding the ground. The collection has been removed and planted in two deep beds of mixed peat and loam with broken bricks, which latter are found to be very advantageous for holding moisture in the light sandy soil of these gardens. The beds are edged with Rhododendron, and bushes of these and Camellias are planted down the centre of each, to provide shade in summer and to protect the young growths from the cutting winds of spring.

A collection of carnivorous plants has been arranged on the table on one side of the Orchid House porch, which it has been necessary to protect from the curiosity of the public by a wire fence.

During the last year practical lessons in various departments of botany and its kindred subjects have been given to the young gardeners with a view of preparing them better for their duties in general, and especially of qualifying them for government and other situations in the colonies and India, where a scientific knowledge of gardening, arboriculture, &c. is required. The lessons are given in the evening after working hours, and embrace the elements of structural, systematic, and physiological botany; of chemistry, physical geography, and meteorology in their application to horticulture; of economic botany, forestry, &c. They are given, some in the young men's library, others in the garden or museum. Attendance is not compulsory, but anyone commencing one of the courses is required to go through with it and take notes, which are written out in books, and these are examined periodically. The courses are short, and some of them are repeated twice or oftener during the year, so as to enable a succession of young gardeners (who cannot well attend to more than one course at a time) to obtain instruction in all or most of the subjects taught.

It should be premised that no young gardeners are taken into the service of the Royal Gardens who have not passed their apprenticeship elsewhere; that they come ostensibly for the purpose of self-improvement, and are expected to remain for two years in the service. They, however, seldom remain more than twelve or eighteen months, the fact of having served at Kew being considered so high a recommendation for curatorships of botanic and other public gardens, and by persons requiring gardeners with a special knowledge of plants, and the demands upon Kew for gardeners to serve in India and the colonies being very frequent.

A large stock of the true Liberian Coffee has been obtained through the kind efforts of Messrs. Irvine & Woodward of Liverpool. This is a larger and perhaps different variety from that received from Cape Coast, and which was mentioned in my last year's report (p. 5). Large quantities of both have been sent to the Coffee-growing British possessions, and have arrived in excellent condition.

Dr. Thwaites states that the Cape Coast Coffee, the safe arrival of which in Ceylon I mentioned in the report of last year, is, notwithstanding that it was immediately attacked by the leaf disease, doing well. He also remarks that "the Cape Coast and Liberian Coffees, although they would seem to differ much as regards size of their respective seeds, yet in the matter of foliage there is great resemblance between them. In this latter respect they differ considerably from the ordinary Coffee plant of Ceylon; their leaves being a good deal larger, more firm in texture, and tapering more gradually to the base."

The disease and insect ravages by which of late years Coffee has been attacked in India, Natal, Ceylon, and other colonies has directed the attention of the Local and Home Government to this important culture, and given rise to a very extensive and onerous correspondence with this establishment. My attention has in consequence been directed—(1), to obtaining accurate reports as to the nature of the disease, of which several are confounded under one common epithet; (2), to recommending measures for the cultivation of Coffee in

colonies once famous for its production where it has been almost abandoned, as well as in others where the cultivation has been scarcely attempted; and (3), to the cultivation of new and improved varieties.

The demand for seed of *Eucalyptus globulus* has continued unabated. I am still unable to endorse the views of those who regard the tree as capable of cultivation in tropical swamps and as a prophylactic against ague and fever. But whilst responding in this sense to the multitudes who write to me on the subject, I have accompanied my answer with a packet of fresh seeds for trial. There is little doubt, however, that in places which are favourable to its growth it will prove a very valuable source of timber of hard quality, and, contrary to the usual habit of hardwooded trees, it is of very rapid growth.

The subject of Cinchona cultivation in the now almost abandoned colony of St. Helena has been again brought under the notice of the Government, owing to the fact of a large proportion of the trees introduced there ten years ago from Kew, and whose culture had been abandoned, having been found after years of neglect to be in a flourishing condition. The suitability of the soil and climate of that island for Cinchona cultivation has now been indisputably proved, and the question of continuing and extending it is one that must depend upon other considerations. The successful introduction of this febrifuge into India, Ceylon, and Jamaica being now accomplished, this subject no longer demands a notice in my report.

The prospect of Ipecacuanha cultivation, which is no less important than that of Cinchona, is far less encouraging. This arises not so much from want of success in establishing and increasing the plant, as from the apparently extremely slow growth of the underground rootstock from which the drug is obtained, and the small yield of even a fully grown plant. Nevertheless, the cultivation must be persevered with. The causes that retard the progress of this valuable herb under cultivation are those that raise the price of it in its native country. Were it a plant that increased rapidly, it would be with difficulty eradicated in the forests which it inhabits.

The plants of the true India-rubber of Para (*Hevea brasiliensis*), which had been taken out to India by Dr. King, Superintendent of the Calcutta Botanic Garden, have safely arrived and have already to some extent been propagated by cuttings. The cultivation of this tree is extremely important, not merely from the valuable quality of the rubber obtained from it, but also in view of the diminished supply from the Indian *Ficus elastica*, which, owing to its epiphytic germination and mode of growth, is not well adapted for cultivation for this purpose, while severe inroads have been made upon it in the forest where it occurs.

## NOTES AND GLEANINGS.

A LOAN has enabled the Royal Horticultural Society to pay not only the prizes they offered in 1875, but those also of 1874. The Society also purposes to renew its PROVINCIAL SHOWS, and that the first shall be held at Liverpool during next June.

SUTTON & SONS' ROYAL BERKSHIRE ROOT SHOW is to take place on 20th November. It is said to be now the largest in the kingdom. £220 are offered in prizes. The prizes for their Champion Swede amount to upwards of £35, and Mangold prizes in the aggregate to upwards of £80. There is the novelty of a special class for roots cultivated with sewage; and prizes for vegetables and Potatoes.

## NOTES ON VILLA AND SUBURBAN GARDENING.

GATHERING AND KEEPING FRUIT.—Some may ask, What has this to do with villa gardening? My answer is that it is one of the most important operations of the season. To take the pains to grow fruit, and neglect the essential points in gathering and keeping it, is like throwing time and labour away. It is not to be expected that in the usually limited conveniences appertaining to a villa residence that there is a proper place for storing fruit (even professional gardeners often find places deficient of that necessity), but here there is a strong reason why more care should be taken in gathering the fruit; for depend upon it the more care that is bestowed upon the different sorts of fruit the longer and better it will keep.

Now let us see what ought to be our guide. First, in the work of gathering, it is a wise provision of Nature that all the fruit upon a tree does not ripen at one and the same time: hence the importance of knowing when a fruit is ripe or fit to gather, and in the best condition for use. Take Peaches and Nectarines, for instance; their natural colour upon the tree often leads one

to think they are ripe when they really are not. One way to test these is to take a gentle hold of the fruit between the thumb and second finger, let the finger be the testing agent by pressing the fleshy part of the fruit close or near the stalk; if this is soft the fruit may be safely gathered. But even then I consider that by laying the fruit on a clean paper in a sunny spot under cover sometimes for twelve or twenty-four hours it is better fit for table than when fresh gathered; though here the fruit must be watched and used at the proper time, or its richness soon deteriorates. Late sorts of Peaches are seldom so good in flavour as the early and midseason kinds, and require to be gathered a longer time before use.

Apricots are perhaps the most peculiar fruit of any to secure properly ripe at all parts. It often happens that the part of the fruit most exposed to the sun has a rich-looking colour about it, and is ripe first there, but at other parts is quite hard; therefore the test applied to Peaches will hardly answer for Apricots, and if they were allowed to hang upon the trees, to which they adhere very firmly, till the under part was ripe the other part would be worthless. I generally expose my fruit to the sun as much as possible by pulling off all overhanging leaves, and then gather when the under part of the fruit is nearly of the same colour as the top, and lay it out for a day or two it is fit for table. As to Plums there is not much difficulty, for they readily part from the twigs when ripe. Cherries, the dark sorts tell by their richness of colour, and the light-fleshed sorts by their transparency. Of Figs my old tutor used to say they are ripe when the small end was of the same colour as the largest end; however, I found that by waiting for this I was often disappointed, for not only did the fruit not all colour alike, especially the Brunswick and Brown Turkey, but the fruit often split at the top, and then it soon spoils. I gather as soon as the eye at the top begins to open and the seeds exposed turn to a brown colour, and if the fruit is soft there is not much wrong.

Of Pears there is an amount of judgment needed, for some sorts, such as the Jargonelle and Williams' Bon Chrétien, should really be gathered before they are quite ripe. I mean that if allowed to remain on the tree till they colour, within twelve or twenty-four hours after that they are not fit for the dessert. Like some sorts of Melons they are ripe before they show it, and especially so if grown on a wall. One test is by cutting a likely-looking fruit asunder, and if it has good flesh, with juice exuding from the cut, and the kernels are black, it will be pretty safe to gather. With regard to late Pears, such as keep over Christmas till spring—that is, Easter Beurré, Winter Crasanne, and Winter Nellis, as well as others, they must be gathered when the kernels have changed from a white to a brown colour, for they do not ripen on the tree, but require to be laid up a considerable time, or till their season comes round.

Of Apples the early dessert kinds, such as Juneating, Irish Peach, and Red Astrachan are tested by the same means, and so are the Codlins and other early kitchen kinds. There are other means of testing: One is to observe when they begin to fall from the tree; and another is to raise the fruit up just above the level of the string, and if it is ripe it will part quickly from the tree, and Pears may be safely tested in the same way.

All fruit should be gathered when dry, and be put into a basket upon some soft material to prevent bruising.—THOMAS RECOR.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

We continue to store the earlier sorts of Apples and Pears as they are ready for gathering. Pears are gathered at different times from the same tree, at intervals of say a week or ten days, in order to prolong the season. The earliest gathered will ripen first. We are now using Williams' Bon Chrétien from standard trees. Other fruit from the same trees has just been gathered, and will not be ready for two weeks longer; by that time the earliest Louise Bonne of Jersey will be ready for use, and also Fondante d'Automne, Beurré d'Amanlis, and Beurré Hardy.

Plum trees are actually being broken down with the weight of fruit, especially the large kitchen Plums, such as Pond's Seedling, Diamond, Victoria, &c. The Bullace trees, although the fruit is not large, are so overloaded with it that many branches have broken with the weight—some of the trees we propped-up with sticks. It is a mistake to allow the trees to bear such enormous crops, and if time could be spared it would be much better to go over the trees and thin out the fruit early in the season, that which was left would be of much superior quality, and the trees would not suffer; besides, such enormous crops are not required, as much of the fruit is wasted. Those who have recently planted trees should now take notes of them, as it will be necessary to do away with some of the sorts however well selected the collection may have been. Many varieties of fruit trees that do well in some gardens, in others are quite worthless; but it is best to give the trees two or three years' trial before discarding them. Plums generally do well with us

planted out as pyramids, but Braby's Green Gage and Reine Claude de Bavay, both very large late Gage Plums, have after seven or eight years' trial failed to give satisfaction, and as the trees are such rampant growers they must be removed. The fruit cracks and decays before it ripens.

Amongst Pears many varieties that produced fine, large, clean fruit on the excellent clayey loam in the nurseries of the Messrs. Rivers of Sawbridgeworth, are quite worthless in our soil; two of the best are Doyenné du Comice and Beurré Superfin. The fruit with us is always diseased and cracks badly. Beurré Rance was obtained double-grafted, but the fruit which is produced in abundance never grows to its full size, and also cracks badly. In good seasons we have had tolerably good fruit, but it is too uncertain to be allowed space any longer. When trees that have grown six or seven years in one place are removed it is necessary to trench the ground deeply, and to add some rotted manure and fresh loam; placing some rotted turfy loam round the roots of the trees when planting them is also very necessary.

Peach and Nectarine trees on the walls should be looked to as directed two weeks ago, and the shoots that are loose to be nailed-in, not only to improve the appearance of the trees but also to allow the fruit to ripen and colour well. Any fruit that is shaded with leaves should be exposed by having the leaves laid aside by the hand, or picked off, and this is the more necessary with late Peaches.

The same may be said about Vines on walls. Wasps and flies attack the berries before they are ripe, and the best way to protect them is by covering each bunch with gauze bags. Where the lateral growths are crowded it is best to thin them out and to nail the loose shoots to the wall. Many amateurs and cottagers in the south grow very good Grapes upon walls. In favourable seasons Black Hamburgh ripens well, and the Royal Muscadine seldom fails to produce good crops. Dust with sulphur on the first appearance of mildew. Many persons say that Grapes cannot be grown out of doors as they used to be grown. Probably the reason is that the same amount of attention is not bestowed upon them as heretofore. We have heard people complain that their Grapes did not ripen well. How could they when leaves and fruit were smothered with mildew, and scarcely any attention had been bestowed upon them from the time of pruning and nailing in early spring until the fruit was gathered? With the same attention that is bestowed upon Vines under glass good crops of well-ripened Royal Muscadines can be obtained nearly every season.

We look over the Strawberry beds about once in ten days to cut off the runners that are abundantly produced on the young plants; we have also run the Dutch hoe through the rows once since the plants were put out early in August; they will be hoed again in a week or so. The plants are now free from red spider; if it were not so, watering them with soot water two or three times would destroy the pest. Hoe the ground everywhere if there are any weeds.

### VINERIES.

If the fruit is not quite ripe in the late houses a little artificial heat should be applied to ripen it; indeed, the temperature at night should not fall below 65°, with the ventilators a little open both at the front and back of the house. Plenty of ventilation is requisite by day, but the temperature should be kept up to 70° if the days are cloudy, and 5° or 10° higher during sunshine. Any shrank or mouldy berries should also be removed at once with the thinning scissors. It is not desirable to have plants in the house at this season, but if it cannot be avoided care should be taken in watering them that no water be spilled about unnecessarily.

Pot Vines intended to bear fruit early next year, and that will be started about the end of October or the first week in November, should now be cut back to the required length. The pots should be placed in a house where but little artificial heat is used, and no more water be given to the roots than is sufficient to keep them moist and in a healthy condition.

### GREENHOUSE AND CONSERVATORY.

We shall as soon as convenient remove the hardwooded plants that have been out of doors for the summer months into their winter quarters. Before doing so the pots will be cleaned, and the plants be tied and have all withered and decaying leaves removed. The drainage should also be free from any obstructive material; the health of the plants very much depends upon the free outlet for superfluous water. The plants ought not to be placed in a position where worms can work up into the pots. To prevent this we place the pots on a couple of bricks. A stout stick is also driven into the ground close to the pot, or if the pot is large two or three sticks. The pot is fastened to the sticks, and there is then no danger of the wind turning the plants over. If worms should get into the pots it will be necessary either to turn the plants out and to examine the roots, or water with lime water. When the plants are all arranged in the greenhouse the ventilators should be fully open night and day until the plants become accustomed to their new quarters; and if the weather is very dry it may be desirable to dew the plants

of unconsumed gas entering the house, would answer, though we should prefer a gas-heated boiler with 2-inch hot-water pipes.

**GRAPES SHAKED (E. W. C.).**—The footstalk of the bunch you sent us is badly shanked. It is caused by the roots not supplying sap to meet the demands of the leaves and fruit. See answer in last week's Journal to "T. Upton," page 210.

**ASH SEEDLINGS ON WALL (Narberth).**—Cut them down as soon as the slightest fresh growth appears, and if you continue the cutting they will die of exhaustion. Applying an acid to the stumps would injure the wall. The new issue of "How to Farm Two Acres Profitably," is now ready.

**AMARANTHUS PRINCESS OF WALES (W. Hender & Son).**—The exemplar sent are unusually brilliant in colour, and the variety promises to be an acquisition for decorative purposes, especially as it is easily raised from seed.

**PEACHES DEFICIENT IN FLAVOUR (J. R. W.).**—There is no reason why the Peaches should not be good-flavoured from your house if you manage them properly. Soil has very considerable influence on flavour, but in any sort of loam good Peaches can be produced from sandy loam to heavy clay. As the roots are inside, too much or too little water would cause the fruit to be as you state. You should maintain a high temperature as soon as the fruit begins to swell after stoning, and up to the time that it begins to turn soft. If you study the "Doings" under the heading of Peach House you will obtain all the information you require.

**LILUM GIGANTUM CULTURE (J. M. T.).**—We grow this noble Lily in the same sort of soil as the others, but it will not succeed if it is freely exposed to the sun and air. The plants succeed best if placed under a low wall facing north, where the sun shines on them a few hours only in the afternoon. They must be grown in rather larger pots than the other sorts. It is best to use a garden frame or any other glass protection, although they will do quite well in the open air during the summer months.

**CONSTRUCTING A VINERY (E. P. N.).**—The height of the back wall being 15 feet, and the front of the vinery 5 feet, 2 feet of brickwork and 8 feet glass, the width of the house for an 18-foot rafter would be about 16 feet, including the front plate; but as you do not give us the height of the front, you had better ascertain from a carpenter what the width of the house will be with a 5-foot front, and the roof a pitch or fall of not less than 1 foot in 3 feet of space covered. A house 80 feet long would not more than about one-third pay the interest on first cost, and working expenses including gardener. A house 100 feet long would be necessary for what you seek. So small a house as 80 feet would be best without a division.

**CULINARY PLUMS (A. B. G.).**—The following will succeed as standards:—Early Rivers, Early Orleans, Prince of Wales, Victoria, Prince Engelbert, and Diamond.

**NAMES OF FRUITS (E. B.).**—Washington Plum. (Mr. Jackson).—Peach Pear.

**NAMES OF PLANTS (Rosery).**—The spray is of the Tamarisk; the leaves we cannot attempt to identify. (H. S. James).—*Gymnocarpha chrysophylla*. (J. A. D. S.).—1, *Veratrum viride*; 2, *Clethra integrifolia*; 3, *Centranthus ruber*; 4, *Gymnocarpha* sp.? (*Hidenborough*).—1, Abutilon, but we cannot decide the species; 2, *Polygala speciosa*; 3, *Andromeda* (*Leucothoe*) *axillaris*; 4, *Carya* sp.; 5, *Erythrina*, perhaps *herbacea*; 6, *Euphorbia portlandica*. (G. McAdam).—*Funkia ovata*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LARGE PRICES.

FROM the earliest weeks of the present year we have had our doubts as to the quantity and quality of this season's exhibition chickens, and from time to time we have hinted at the same in our papers in this Journal. We will not now discuss that matter, as later on we may give a brief recapitulation of the various successes in the different breeds, but the fact is fully substantiated by the immense prices that good chickens have fetched and are fetching this year. As a rule the summer exhibitors do not care to give long prices for birds for the summer shows, as such specimens but very rarely win in the autumn, and are usually of little or no use for the breeding pen. The knocking about they have when young, and the stimulating diet seems to upset them, and they very rarely appear to advantage against the fresh autumn-reserved birds, which not only will bear much of winter work, but will with care also be valuable additions to the breeding yards. This season, however, we have heard of almost double the ordinary prices being given for single chickens (Cochins, Brahmas, and Dorkings especially), for the summer shows, and this leads us up to the subject of the long and fancy prices for cocks and hens, and brings to our recollection the immense sums which have been paid for birds during the past few years.

Mr. Lingwood and Mr. Wragg must have made small fortunes of their Dark Brahmas and Buff Coochin cockerels and pullets. We heard last winter what they received for their best birds, and the prices were something marvellous. Fifteen pounds was thought an immense price years ago for a fowl; now £25 is thought nothing of. We believe Mr. Wragg last winter sold Lady Gwydyr's cup Crystal Palace Buff Coochin cockerel and pullets for close on £80, and we know for a fact that at the same show Mr. W. C. Burnell was offered £52 10s. for his adult Buff Coochin cock and refused the offer. Perhaps the latter is the highest sum that ever has been offered and refused for one single specimen; but we can tell of some tremendous prices which single birds have realised.

High-class specimens of the popular breeds always command a good and speedy sale. Fine specimens weekly are fetching £15 each, but the world knoweth it not. One or two friends of

the vendor may hear of the good sale, but beyond that the matter goes no further, and is thought of as a common everyday transaction. This fact shows us in a very striking way how deeply rooted our poultry fancy is, for we confess we had our qualms as to whether this late unfortunate season would not shake many amateur poultry-yards to their very foundations, but it seems not to have done so to any extent; and, as we before said, from the prices birds are fetching fanciers would seem to be buckling-to for the fray with greater zest and eagerness than ever.

We have noticed this season, too, that in many instances those who have, or have had, good early chickens are amateurs; and though their best may have been bought-up by the great exhibitors, and so found their way into their exhibition pens, still we are extremely glad to note the fact, as it shows us that considerable time and trouble must be brought to bear on the breeding of poultry, for we all know that perfect high-class specimens cannot be easily produced.

We will give a few prices which birds have fetched in the last two or three years, as they may be interesting to some. We have stated how well Messrs. Lingwood and Wragg do, and Mr. Burnell does not come far short of them. We saw his cup pen of chickens claimed at Oxford in 1873 for £21. We know he sold two cockerels last year for £20 each, and had within a pound or two almost as much for a dozen more. And now we hear he sold his first Coloured cockerel at Bath last week for £26 5s., the purchaser being the Rev. Hans Hamilton. In 1874 Mr. Beachey sold a cock and two hens, White Cochins, for £52 10s. At the last Palace Show Mr. Graham sold four Dragon Pigeons for £75, for Pigeons fetch as high prices as poultry when really high-class birds, and yet they do not cost one-quarter the money, and none of the actual and incessant trouble in feeding and rearing which poultry do. At the Crystal Palace, too, that great place for sales, a Dark Brahma pullet of Mr. Peake's, a Brown Red Game cock and several more birds were quietly claimed for £20 each; and at Bristol a few weeks later the first-prize White Coochin cock and the same exhibitor's highly commended pullet were sold for £40. And so we could go on for a long time, but we need not particularise any more instances, for we have said enough to point out an important fact. Whether these long prices actually benefit the fancy much we need not here go into, for we all know there are a certain number of exhibitors who, rich in this world's goods, make poultry a hobby and will win, and to do this they have very frequently to buy the coach birds of the time, and consequently have to pay heavily for them; and we know these are the people who keep the long prices up, and very likely to some great extent help to keep up and cement closer together the various stones which compose the poultry fabric.

These high prices which we have quoted, however, have all been given for Cochins and Dorkings, and specimens of the popular breeds. Certainly we know of £10 10s. being given for the first prize 1874 Palace Silky cock, but this was an extraordinary price for a bird of such an uncultivated breed; and, consequently, the fact these prices teach us is, that to the popular breeds many should turn who, perhaps, are now keeping a variety which, not being much sought for, is neither found often in the prize list, or whose specimens do not command good and steady sales. We would not for a moment wish to disparage our Leghorn, Andalusian, Minorca, Sultan, Silky, and other such-like friends—very far from it, for we have the greatest regard for them, and never lose an available opportunity of advancing their interests. But we would recommend those who have means for keeping two varieties to have two strings to their bow, and try to raise some good chickens which will fetch such prices as to stimulate the poultry-keeper, and at the same time help to keep the pot boiling in so substantial a manner.

Amateurs with ordinary advantages can and do do this; and as it is for amateurs we write, we hope that they will turn their attention to the subject, and so be the means of building-up more strongly than ever this poultry fancy which is so interesting to many of us.—W.

### AIRDALE SHOW OF POULTRY, &c.

THIS Show was held in Myrtle Park, at Bingley, on Wednesday the 1st inst. Poultry were in the open air, but in excellent pens, the backs and tops of which were covered with cotton, a point we would draw the attention of other societies to, as being one of great protection to the fowls. Pigeons were, however, provided with a capital marquee, and the pens being of the most approved pattern they looked well.

Game were the first on the list, with a class for Red cockerels (the whole show was for young birds), the first-and-cup going to a promising bird, a Brown Red, but very young; the second a good bird, fuller of colour, but a little overgrown; the third a moderate bird, though we liked pen 6 (Martin) full as well. In pullets the winners were also Brown Reds, the first forward, good in colour, but long in body; second a fair bird, as also the third, but this we thought rather overtrimmed, but otherwise

the best. Any other cockerel was a Duckwing, superb in all points; the second and third also fair Duckwings. In pullets we should have placed pen 5 (Mason) first, as by far the best, all points counted, a Duckwing; second and third were Duckwings, and first a Pile, the latter, however, very good. Buff Cocks forward and large; the second and third-prize pullets almost as rich as a finely-peppered Canary; the first not so good in colour, but the cockerel a little larger perhaps. Partridge won the cup, these being a nice lot, and the awards well made. *Brahmas*, Dark, a fair lot, the winners standing clear of the rest. The first-prize Light Brahmas were very good in size and marking; the second also a nice lot. *Spanish* very good; the cup for this section was given here. *Dorkings* good, as also the *Poizants*, in which Golden won. *French* low were a moderate lot, the *Créves* by far the best. *Hamburgs*, Gold-spangles, a grand pen first, the rest fair. In Silver-spangles we thought the second best, though a little later, but both were nice pens. Gold-pencils a good lot, the winning pullets most beautifully pencilled. Silver-pencils not as good as Gold, with the exception of the first, to which the cup was given. Black Hamburgs moderate as a lot, but the awards not well made, and reversed from the Halifax Show; the first at the latter place were only highly commended, while the highly commended pen were placed first. Pen 4, not noticed, were worthy of first. *Bantams*, Game, first-and-cup were a neat pen, but the cock short of colour; second the best cockerel, but pullet poor; third Brown Red, large, but very good in style and colour. Bantams any other were first Silver Sebrights, very good, but rather large; second Blacks, good in all points but combs, which were too high; third very fair Blacks. Of Selling class we have no notes of interest.

*Pigeons* were a grand display, the list of prizes being liberal and tempting, and here was a mishap; Captain Heaton, being advertised to judge, had missed his train, and others had to be called in to do duty. Messrs. Beldon and Frith kindly consented to judge all except what the first-named gentleman termed the mongrels—Antwerps—at which he evidently took fright; and this section was judged by Messrs. Hutton and Hawley. In Carrier cocks first was a grand Black, with splendid eye and beak; second a good Black, and third a light young Black. In hens first was a grand young Black, with splendid beak; second a good Black, much heavier and older; and third a nice Dun. Carriers of 1875 were strong young birds. In Pouters first-and-cup a Blue cock in splendid show, good limb and style; second a Blue, perhaps a little better in limb, but scarcely as well up; and third a good White. Hens first and third White, and second Blue; a nice lot. Almond Tumblers very good and well placed, although the Rochdale first was only highly commended. Other Short-faces, were first a grand Kite, second a Red Wholefeather, and third Yellow Agate. In Barbs the cup was awarded to a very good Black cock, second a Red, faulty in colour, and third a Red. English Owls were a good and large class, and the winners all Silvers. In Jacobins we thought pen 1 (Swallow) the best, this being a grand Yellow. The first was awarded to a Yellow a little foul-fighted; second to a capital Red, and third to very good Red. In any other colour first and third were Blacks, and second Whites. Fantails were grand and well placed; the first was an exquisite bird. In Turbits the second Blue was best; first was a Blue, grand in head, but foul-thighed; third a good Yellow. Antwerps, a class entirely unknown a few years ago, were a show in themselves, there being 107 pens shown. First were Short-faced, with twenty-seven entries, though only twelve birds were noticed; first-and-cup for the best in the Show a Silver Dun, correct in every point, and just getting clear of the moult; second a Red Chequer, good in all points but gullet, of which it is deficient; and third a Short-faced Silver Dun, not as round in head as some, but with general good properties; and extra third a very stout Silver Dun; the other noticed birds being very good, but many were but Medium-faced. Medium-faced were a good class, perhaps as even as any, with twenty-three entries; the first going to a grand-coloured Silver Dun; second to a Red Chequer hen, which gave the Judges some difficulty, appearing a little too good in head to be genuine; third a grand Red Chequer, but a little splashed with Black; and extra third a capital Dun, which would have been higher only that he is a little too short in face. Long-faced had nineteen entries, and almost all were noticed, this being a class of very strong birds, feather and condition in many cases determining the prizes; the first a Red Chequer cock, second a Red Chequer hen, the third and extra third also of that colour were cocks. In Antwerps of 1875 there were thirty-eight entries, and in consequence the prizes were allowed in duplicate; the first going to a grand Short-faced Dun, and an extra first to an equally good Long-faced Dun; second a Red Long-faced, and extra second a Medium-faced Dun; the third to a Medium-faced, as also the extra third. Dragons, Blue or Silver, was won by Blues in all cases. In the other colours Yellow, Red, and Yellow won respectively. Dragons bred in 1875 were not good as a class, but the winners were superb; first a Silver, second Yellow, and third Blue. In

Gamon, Chester; J. Wright.

*Antwerps*.—Medium-faced.—1, J. Holden, Wibsey Black, Bradford. 2, J. Lister, Keighley. 3, W. Ellis, Idle, Leeds. Extra 2, H. D. Gough, Wakehampton. 4, C. F. Copeman. Ac, J. Lister; R. Brierley; W. Brook, Baildon; J. Young; Ward & Rhodes.

*Antwerps*.—Long-faced.—1, W. Ellis. 2, W. F. Entwistle. 3 and Extra 2, H. Jennings, Allerton. 4, J. P. Rothwell; W. Ellis; H. Jennings; T. Hutton, Baildon; W. Gamon, Chester; R. Hutchinson, Littleborough. Ac, J. Cockitt; R. Rawnsley.

*Antwerps*.—Young.—1, H. Yardley; W. Illingworth, Wilsden. 2, W. Ellis; J. Wright. 3, J. Wright; H. Jennings. Ac, W. F. Entwistle; R. Rawnsley; J. Kendrick, Bodditoh; H. D. Gough; J. Greenwood, Morton.

*Dragons*.—Blue or Silver.—Cup, F. Eastwood. 3 and 2, R. Woods, Mansfield. Ac, W. Smith, Liverpool; R. Wood. Any other colour.—1 and 2, R. Woods. 3, Wells & Sherwin, Ripon. Young.—1 and 2, F. Graham, Birkenhead. 3, R. Woods. Ac, S. Wade, Baildon; G. E. Chavasse; W. Smith.

*Tombles*.—Long-faced.—1, W. Ellis. 2, J. Cargill, Hovingham. 3, Eldley and Dye. Ac, G. E. Chavasse; E. M. Beckwith.

*ART OTHER VARIETY*.—1, J. Baker. 2, E. M. Beckwith. 3, T. Shackleton. Ac, T. G. Sprunt; R. Fulton; E. M. Beckwith; S. Lawson; J. Baker.

*SELLING CLASS*.—Single Bird.—1, R. Rawnsley. 2, T. Foster. 3, S. Lawson. Ac, J. Blanchard, Driffield.

*SELLING CLASS*.—Pair.—1, R. Rawnsley. 2, S. Lister, Keighley. 3, W. Ellis. Ac, W. Lund, Shipley.

*JUDGES*.—Poultry: Mr. R. Teebay, Fulwood, Preston; Mr. J. Dixon, North Park, Clayton, Bradford. *Pigeons*: Messrs. Beldon, Frith, Hutton, and Hawley.

**DARLINGTON BIRD SHOW.**—The schedule gives thirty-two classes, with prizes of £1, 10s., and 5s., to twenty-eight of them, and to four classes of British birds—the Goldfinch, Brown Linnet, Bullfinch, and any other variety of British bird, prizes of 15s., 10s., and prize cages and a plated tea-pot. The entries are announced to positively close on Saturday, September 26th.

**Mrs. ACTON TINDAL'S BUFF COCHIN COCKEREL** which won the cup at Birmingham was not bred by Mr. Wragg, as stated by the writer of "More Remarks on the Birmingham Summer Show." We have letters from Mrs. Tindal, from her poultry manager, and from Mr. Wragg, all stating that the bird was not

bred by Mr. Wragg; and the two first-named state that Mrs. Tindal never shows any birds not bred by herself.

## BATH SHOW OF POULTRY, &c.

SEPTEMBER 1ST, 1875.

PARTRIDGE or poultry? Capital oveys we knew of tempted one way, pleasant recollections of the last Sydney Garden meeting tempted another way; but we needed no subtraction sum to find out that whereas we had only two days for Bath, we had many weeks for the Partridges. So to the town of buns, chairs, and olivers we betook ourselves. We certainly did feel a tiny bit of envy as we passed quickly in the early morning through the spider-webbed fields among the silvery mushrooms, and saw the dogs about, and heard the first bang of the day; but then we remembered the courtesy of the Bath officials last time, and hoped for as pleasant a reception this year. When we arrived at the Show, however, we found a most terrible blank in the ranks of the Committee. Mr. Holmes, where was he? Mrs. Holmes, where was she? Can we ever forget how the latter lady laboured nearly all the night through among the birds last year, working for the good cause of their Show? Why, she was worth half a dozen of any ordinary committeemen herself, and now this year we found her and her husband missing from the party. We, of course, inquired the reason, and when we heard how the case stood we could only feel glad that Mr. Holmes had resigned, and congratulate them both on being out of the worries and troubles. But still their absence was a considerable loss, and many felt it extremely. The Judges were Mr. Hodson and Mr. Tegetmeier; the former for poultry and the latter for the Pigeons; while Mr. Blakston adjudicated on the cage birds, and he with Mr. Tegetmeier also judged the Rabbits. It is always an unsatisfactory job to judge a large show where the classes are for adults and chickens together, but we thought each Judge performed his arduous duties most efficiently; of course we differed in some few awards, but they were mostly very carefully made.

The poultry and Pigeons were shown in a large tent, while the cage birds were exhibited in the summer alcoves, which being tastefully decorated made a pretty addition to the show-yard. Turner's pens were used, and the feeding and management were good. We must not forget to say, however, that on the first day from 1 p.m. to 2 p.m. every visitor had to pay 5s. 6d. to go in, and after then 3s. 6d. These charges are simply exorbitant; but the fact is everyone had to pay to go into the flower show, and then again to pass through the poultry barriers.

*Dorkings* came first in the catalogue, and Mr. Burnell easily walked in his Coloured cockerel. He is a splendidly-made bird, and good in colour and feet. Second went to an old bird out of feather with a bad upper toe, but otherwise good. Pen 1 (Briden) was a large chicken, but poor in comb and rather knock-kneed. We liked pen 8 (Feast) very much, but he had too much white in his tail. In hens the winner was a grand rose-comb from Little Ness, second going to a good hen of Mr. Burnell's, which, we believe, was sold on the ground. 14 (Beachey) a very large dark pullet, and promising to make a huge bird, but she was rather sooty on her feet, or would have been in the list most probably. In the next class a splendid Silver-Grey won first, being good all round; second going to a nice White, save that his comb was faulty in peak. In hens a good White was first, and a very nice White pullet second, third going to a nicely-coloured but small Silver-Grey. We miss Mr. O. E. Cresswell's name in these classes this summer, and are sorry to learn he has had to leave England for change of air owing to delicate health.

*Cochins* were not as good as we expected. The winning White cock deservedly won the cup. He is good in all points, only has lost one serration in his comb. The second was also an adult White, but he was moulting, and looked ragged in hackle and tail. Third, the winning Birmingham cockerel, a fair chicken, but one which will never make a large bird. White hens were only moderate. The best shaped hen in the class was 38 (Feast), but she was not large and hideously dirty. In the other two Cochins all colours had to meet. In cocks a good Partridge won first, second going to an old Buff. In hens Buffs won all the prizes, first being an old hen, rather faded-looking and seedy; second was a lovely pullet, and preferable we thought to the winner.

Dark *Brahmas* were splendid. The two champion cups went to these two classes. Mr. Ansdell was indeed fortunate, but his birds deserved their honours. His winning cock and prize hens were adult birds, and had moulted-out as clean and bright as possible. In hens the third went to a fine pullet, well-feathered and clear in markings. Light *Brahmas* were two wonderful classes. Cockerels won all the prizes in the first class. Mr. Dean's bird only came in second, but we believe he bred the winner. All his birds were large and well-grown birds, but they were rather too creamy on the back. The third was very symmetrical and pretty, with a charming head. 83 (Scammell)

good, but poor in comb. 80 (Petter) we liked immensely, and thought it was hardly used. In hens a finely-shaped pullet was first; she certainly was not a good colour, but her other points were perfection. Second a good old hen, well shown. Third a nice pullet, but we infinitely preferred 96 (Petter). It was a glorious class, and the pullets were a wonderful lot.

*Game* were not large classes, and the chickens few. In Red cocks or cockerels a finely-shaped old Black Red won, but he was generally out of feather; second a fair Brown Red; third a Black Red, too thickly made, but good in head. Hens were a fair class, and the winners about right. In the other Game classes an adult Pile cock with very brilliant yellow legs won the cup. He was in good feather, and bright in colour. 128 (Winwood), a nice undubbed Pile cockerel. In the next class we admired the second pullet very much, and should almost have placed her before the winning hen.

*Hamburghs* were very nice, in fact quite a superior collection. The cup went to a very good Golden-pencilled cock, just beginning to lose his tail feathers. The other winning Pencilled cocks were also good. In hens the winner was clear in markings and a nice bird generally, but the Spangled cockerels were the cream of the *Hamburghs*. The winning Silver was a gem in all points save legs, and these were too white, but his tail, bars, and head very grand. Second a splendid Gold, one of the best chickens we have seen for some time. For third we should have gone to Mr. Long's Golden. It was but little behind the second-prize bird, and promises to make a beauty. In hens a nice Silver was first, and a good Gold second; this too was a fine class.

*Malays* mustered twenty pens, and paid their way in a truly noble manner. The first cock won the cup; he was in nice feather and condition. Second went to a good cockerel, and third to a smart old bird. 164 (Browne) a good cockerel. 166 (Hinton) a very nice White, which we thought well worthy of a notice. It was a square bird and good in points, though it may never make a monster. The hens were a nice lot and seemed well judged, though we should have liked to have seen two or three good pullets of great promise more highly noticed; among them pens 175 (Brooke) and 177 (Hinton), which contained a very handsome pullet, though in colour a shade too light for our taste.

*Spanish* were small, but good classes. Old birds won most of the prizes, and the winners came from the neighbouring city of Bristol, and were quite up to the standard of Messrs. Jones and Chilcote's usual form.

*Minorcas* had two classes, and we were much pleased with the birds. They were principally Blacks, which with their large combs and brilliantly-hued plumage looked exceedingly handsome.

*Houdans* were good, and an immense number of birds were deservedly noticed. The winning hen was one of the best we ever saw, her markings were what we consider an ideal Houdan should be. We fancy we have seen this hen winning formerly in Mr. Dring's name, but may be mistaken. 226 (Pearce) an exceedingly good bird.

In the other *French* class a splendid La Flèche was first, good Crêves being second and third. In hens Crêves won all the prizes; the winner was a great beauty. The third was also a very nicely-grown pullet.

*Silbies* were very pretty, and attracted much attention. The winners were well placed, though the first pullet was not quite developed enough in claws to please us. It is wonderful how very much this breed is being used for sitting purposes; certainly they are admirable mothers, and for rearing Bantams and Game are invaluable.

In the Ornamental class Pheasants won all the prizes. There were also in this class two good pens of Guinea Fowls, but what can they do against the gorgeous Gold and Silver Pheasants?

The Variety classes were capital. In cocks a grand White-crested Black Polish cockerel was first, one of the best we have seen this year. Second went to a good Golden, third to a beautiful Black *Hamburgh* cockerel of great lustre. 260 (Long) a Silver Poland with huge crest, but he seemed out of condition. 263 (Harris) a fine Black Malay, which we suppose should have gone into the Malay class. In hens a splendid Golden Poland won first and cup, second a grand Silver Poland with capital crest and markings, third a nice White-crested Black pullet, which promises to make a fine bird.

*Game Bantams* were good in quality, but only mustered eight pens in the two classes. Bantams of any other variety made a splendid class, capital Silver-laced being first, good White-booted second, and nice Blacks third. 285 (Boissier) a wonderfully good pen of White-booted, almost superior, we fancied, to the second-prize pen. 291 (Holloway) good Silver-laced.

*Ducks* were good, and the awards seemed quite correct. The winning Aylesburys were very fine. In Blacks Mr. Sainsbury ran his two pens in easily; they were of nice colour and in brilliant condition. Third went to fair birds, but the Duck was too stumpy in body. Mr. Kelleway's pen was empty. There were only two pens of *Turkeys*, both adults and both good.

Geese were a nice lot. Good Toulouse were first, Embden second, and Grey again third. 374 (Snell) a fine pair of Embden.

The Pigeons were a very good lot, the classes being well filled and the quality capital. In many cases the competition was very keen. Messrs. Yardley, Hammock, and Baker bringing each a very fine team of birds. The winning Carrier cock was a beautiful bird, his shape being perfect and head very good. The third Dun cock was also a beauty. The hens, too, were a grand lot; the winner was a beautiful Blue, though the third-prize bird, which we almost preferred to second, pressed closely on her. In Pouter cocks a superb White was first-and-cup. In hens the winner was very smart, and seemed anxious all should see her best points, for she "played" in a very becoming way. Barbs were nice. A splendid pair won first, and the same exhibitor's pen of Duns (416) were a grand pen. Tumblers were admirable classes. The competition was very keen, but Mr. Hammock's birds pulled off the cup, and deservedly so, though Messrs. Silvester, Baker, and Yardley showed good birds, and made these two Tumbler classes a show of themselves. Dragoons formed a large class; nice Silvers won first. We noticed a nice pen of Blues, but they seemed to contain two cocks by mistake. Antwerps were good; we saw one or two good individual birds which being put with inferior mates had to be left out in the cold. The Toys were good, but not large classes. Fantails, Turbits, and Jacobins perhaps the best. Somehow Mr. Maynard's Fans did not look so well as usual. A pretty medley in the shape of a Variety class of sixteen pens brought this most interesting department to a close.

The Rabbits were large classes, but the Judges had been hard at work among their other classes for some hours previously, and so they must be excused for any errors. The Committee should most certainly have engaged a separate Judge when they found how heavy the entries were. The two cups fell to Mrs. King's Lop-ear and to Mr. Mason's Himalayan. Among the Lop-ears the first Sandy buck and first and second Tortoiseshells we thought extremely good; the third Himalayan was beautiful in its markings. In Angorians only one pen appeared; this was, however, a nice white animal. The Belgian Hares we went round before the Judges came to them, and we marked the three prize Rabbits for the three places, though hardly in the winning order. Still this shows there could not have been much wrong. The first-prize Dutch was a good Blue-and-white. There were no entries in the Variety class or in that for the heaviest Rabbit. We furnish full awards of all the classes below.

Cage Birds numbered about 180 entries, and a very interesting feature they presented in the Show. The prizes although liberal failed to induce many Canary exhibitors from sending out their birds. Belgian Canaries were somewhat plentifully entered, and it was to a bird exhibited in Class 68 by Mr. J. T. Holmes of The Cedars, Bath, that the champion cup of the value of three guineas was given. The above fortunate exhibitor also gained the turquoise oviform vase of the same value, given "for the best cage of foreign birds or single bird." The Rev. Hans F. Hamilton, Mrs. W. C. Drummond, and Messrs. Adams, Soott, and Long were amongst the more fortunate exhibitors. The foreign specimens in particular were very showy in their gorgeous and varied-coloured plumage. So far as the Canary portion of cage birds are concerned the present period is somewhat inopportune for birds to be sent freely for exhibition, owing to their being just now in the depth of moult. In a very short time we may expect to find them entered in abundance. There were a few good birds in the various classes, some of immense high colour.

**DORKINGS.—Coloured.—Cock or Cockerel.**—1 and Cup, T. E. Barnall, Michel dever. 2, Rev. H. F. Hamilton, Chard. 3, R. Cheesman, Ashford. 4, E. Feast, Hen or Pullet. 5, A. Darby, Shrewsbury. 6, T. E. Burnell, 8, Rev. E. Bartrum, Berkhampstead. 9, E. Cheesman. 10, H. Feast. 11, J. Taylor.

**DORKINGS.—Any other variety.—Cock or Cockerel.**—1, T. E. Burnell. 2, E. A. Postle, Chippenham. 3, Withheld. Hen or Pullet. 1, T. E. Burnell, Mounmouth. 2, T. E. Burnell. 3, J. Long, Bromley Common. 4, E. A. Postle.

**COCHINS.—White.—Cock or Cockerel.**—1 and Cup, C. Bloodworth, Cheltenham. 2, Talbot, Edebridge. 3, J. Turner, Bath. 4, T. H. Waterman. 5, A. Bissler. Hen or Pullet. 1, C. Bloodworth. 2, J. Turner. 3, S. E. Harris, Gazeaux.

**COCHINS.—Any other variety.—Cock or Cockerel.**—1, Hon. Mrs. Sugden, Wells. 2, S. E. Harris. 3, Mrs. Radclyffe, Wareham. 4, Miss M. Dickinson. 5, H. Feast. Hen or Pullet. 1, S. E. Harris. 2, C. Sidgwick, Keighley. 3, G. Bloodworth. 4, H. Feast. 5, Mrs. L. Jones.

**BRAMHMS.—Dark.—Cock or Cockerel.**—1, Cup, and 2, T. F. Ansell, St. Helens. 3 and 4, Rev. H. F. Hamilton. Hen or Pullet. 1, Cup, 2, and 3, T. F. Ansell. 4, J. E. Williams. 5, H. Kacey, T. Lark. 6, J. Evans. 7, F. Lake. 8, T. F. Ansell.

**BRAMHMS.—Light.—Cock or Cockerel.**—1, M. Leno, Dunstable. 2 and 3, T. A. Dean, Marden, Hereford. 4, J. Turner. 5, Mrs. G. Bain, Taunton. 6, H. Stephens. Rev. W. Pearce. 7, T. A. Dean. 8, Mrs. W. C. Drummond. 9, Mrs. J. T. Holmes, Stroud. 10, H. Stephens.

**GAMES.—Black or Brown-breasted Red.—Cock or Cockerel.**—1, J. Mason, St. John's. 2, E. S. Goddard, Stroud. 3, H. Brown, St. Austell. 4, J. F. Lake. 5, W. L. Blake. Hen or Pullet. 1, H. Phelps, Yeovil. 2, J. Long. 3, J. P. James, Swansea. 4, J. Cock. 5, W. T. Eversard.

**GAMES.—Any other variety.—Cock or Cockerel.**—1 and Cup, T. Hassel, Market Drayton. 2, J. Long. 3, G. H. Fitz-Harbert, Sevenoaks. 4, E. Winwood. Hen or Pullet. 1, G. S. Premise, Cirencester. 2, G. H. Fitz-Harbert. 3, J. Long.

**HAKESBONES.—Gold and Silver-pencilled.—Cock or Cockerel.**—1, Cup, and 2, J. Long. 3, H. Pickles, Leeds. Hen or Pullet. 1, C. J. Jackson, Peckham. 2, S. Elliott, Liskeard. 3, J. Long.

**HAKESBONES.—Gold and Silver-pencilled.—Cock or Cockerel.**—1, H. Pickles. 2, T. Blackman, Tettenhall. 3, J. Carr, Swansea. Hen or Pullet. 1, J. Carr. 2, H. Pickles. 3, J. Long. 4, J. Carr. 5, W. Evans. 6, J. K. Harris.

**MALAKAS.—Cock or Cockerel.**—1 and Cup, T. Joint, Barnstable. 2, T. Lecher,

Redruth. 3, Rev. N. J. Ridley. 4, Miss A. Brooke (3). Hen or Pullet. 1 and 2, T. Joint. 3, Miss A. Brooke, Shrewsbury. 4, S. Elliot. 5, Miss A. Brooke; J. Hinton.

**SPANISH.—White-faced Black.—Cock or Cockerel.**—1 and 2, E. Jones, Bristol. 3, G. K. Chilcott, Bristol. Hen or Pullet. 1 and 2, E. Jones. 3, G. K. Chilcott. **MINORCA.—Cock or Cockerel.**—1 and 2, J. B. W. Williams, Devonport. 3, J. Cooke, Exeter. Hen or Pullet. 1, Cup, and 2, J. B. W. Williams. 3, J. H. Hood, Tiverton. 4, M. H. Sturt, G. Rogers (3).

**HOUDANS.—Cock or Cockerel.**—1, W. H. Copplestone, Lostwithiel. 2, F. Brower, Lostwithiel. 3, W. Dring, Faversham. 4, R. K. Penson; E. Handley. 5, Mrs. K. R. Vallance; F. Lake. time." Such cases have been rare. We have been fortunate enough to obtain 50 lbs. of honey from several supers, but the stock hives are so poor that we have commenced feeding several of them to keep them from perishing. I observe that bees about here are fain to quench their hunger by attacking the windfalls under the apple trees. I am not aware that I ever remarked this before, although I have known them in bad seasons attack ripe fruit against walls and elsewhere. The drought of last year in this locality was such that I obtained next to no honey, and had to feed all through the autumn, so that we have had somewhat better luck this year, which is the fifth or sixth bad honey harvest in succession in this part of England.

I advise an immediate and careful overhaul in every apiary of existing stock. All hives strong in population but poorly supplied with honey should have sufficient food given to them at once and off hand to keep them in good health during the next six weeks. Then the grand feeding-up should begin, and be carried on continuously for a month at least. October is the best time for this main feeding, as activity recommences in all places where ivy blossoms abound. If this natural activity be stimulated by ample but gradual and continuous feeding, breeding will go on vigorously, and the hives will be all the stronger both to face the severity of winter, and to start fair with good prospects in the early spring. September is the month of repose for all bees everywhere. The quieter they are kept then the better; therefore I would give a few pounds at the end of August to every hive that needs it—say 8 lbs. or 4 lbs., but all, if possible, in one night. The quicker it is over at this time of year the better, because the excitement and consequent waste are less. As to the later feeding it should be all over at latest by the middle of November, earlier, of course, if you are living in the north of England. Make all snug and tight for the coming winter, narrowing entrances, protecting from damp, and covering up with some warm material.

As for despair, the word should be unknown in our vocabulary. "Better luck next time," is a good saying which savours of hope, and hope has a tendency to work out success. So, brother beekeepers, cheer up! Gather forces for another year's trial of the "busy bee." Those who do so perseveringly will for certain reap their reward.—B. & W.

**ALEXANDRA PALACE SHOW OF POULTRY AND PIGEONS.**—There are twenty-eight cups for poultry and twenty-three for Pigeons, besides good money prizes.

### A CHAT ABOUT QUEENS.

THE Yankee idea of a bee incubator certainly rather tickled my fancy, and it was also news that queenless bees would readily accept a newly-hatched queen provided she had not been with other bees, and agreeable to my promise published in your number of August 19th I sought to put the statement to the test, so this is how I proceeded. Having deprived two stocks of their queens—one a Ligurian, the other a mongrel—each stock immediately made about eight queen cells. Now, previous experience teaches me it is unsafe to leave queen cells longer than nine days after formation if more than one is to be preserved, so on the ninth day I set to work to cut the surplus cells out, devoting them to experimentalising. This work with the Ligurians was merely amusing, but with the mongrels—oh, ye gods! what little furies! I have given up gloves, and don't much mind stinging; but shall I confess it? I never voluntarily disturb this particular stock. So calling my son to my assistance, who put on a look of resignation when he saw the job in hand, we gave them a good dose of smoke, which is as disagreeable to me as it is to the bees, and I rarely make use of my smoker. Off comes the crownboard, and out come the combs one by one. It is a slow job. The bees are very strong, and I want all the queen cells removed, as I intend to supply the stock with one of the pure Ligurians. Groan succeeds groan as I pick out the stings from my finger tips, where I am rather sensitive. My boy's time seems pretty well occupied in the same direction, and I have to call him to the scratch several times. But we get through the frames at last, and grafting-in a couple of cells from my other stock, we are not sorry to reclose the hive.

Having a third stock without a queen I remove a comb with two queen cells on it to that, and leaving the remaining Ligurian cells where they were raised I gather up the mongrels to play with. The question now arises how they are to be kept at the requisite temperature, and be under constant observation at the same time. Having to go to town daily on business, my time with the bees is limited at this season of year to one hour in the morning and the same at night. As a temporary arrangement I pack them in two willow boxes and place them in my pocket for their first visit to the metropolis, where having arrived I rigged-up a hot-water incubator, but it did not act satisfactorily—sometimes too hot, then too cold; besides, I could not very well carry the apparatus backwards and forwards morning and night. So seeking for other warmth I put a thermometer in my trousers' pocket, and was delighted to find the tempe-

perature there about 90°—just the thing. In went a box in each pocket, and I felt as proud as a sitting hen. When bedtime arrived of course the boxes had to go with me, where I cuddled them up warm, notwithstanding a feeble remonstrance from my wife, who the second night startled me out of my slumber with an alarmed cry that she could hear a bee buzzing, and she was sure one had hatched and I had smashed the box! However, it was a false alarm, and after sixty hours of nursing the first young queen emerged, crippled in her wings, which did not surprise me, an experience of former days in rearing moths having taught me that with dry heat such was usually the case.

Now, the birth of this princess happened at a very awkward time, 10.30 p.m., all dark outside, and bees taking their well-earned rest, and they are apt to resent disturbance at night. However, there was no help for it. I was determined not to lose the chance of ascertaining her reception, so out I went with a lighted lamp. Cautiously removing a portion of the crown-board of the aforesaid mongrel stock, out came the bees, and down I threw the young queen into their midst. They rushed at her in an instant. Ah, I thought how much they would have her; but, no, their excitement cooled in a minute. They walked over and round her, but harmed her not. After a few minutes' watching I closed the hive, not wanting the queen cells destroyed, and covering the queen and a dozen bees with a cup queen cage, poured some syrup round it, shut down the hive cover, and left them till morning, when I found her with her retinue quite lively. Having again given a supply of syrup I opened my hive containing the major part of the Ligurian cells. One with the cap open, one torn to pieces, and two still intact. These I cut out after having seen the young queen was active and at liberty; then examining the other hive, where I had placed the frame with two queen cells, I saw one queen free and another just cracking her cell's lid. This I thought worthy of watching, and it was curious to see while the queen worked inside, occasionally protruding her antennae, about half a dozen workers were gnawing the cell outside. The queen was soon out, and notwithstanding her sister was already on the throne, the workers fed and cleaned her in the usual manner. The time at my disposal having now expired I left the two queens, curious to see what would be the result when evening arrived.

The two cells I had last transferred to my pocket hatched within two hours, and I was very anxious to keep the queens till evening to continue the experiment. By constant attention I succeeded in this. It has been stated a queen bee cannot feed herself; this is wrong. If a queen be hungry and she crosses some honey she puts forth her tongue and feeds, but she does not seem to scent food as a worker does, and very quickly starves. After four hours' fast she will usually be found too exhausted to stand. My two young queens I fed every half hour, and was generally obliged to put the syrup almost to their mouths before they would discover it.

I am much inclined to think queens do not fight to the death as has been so often described. We are all apt to repeat statements, and their very repetition stamps them as credible. I as an author do not claim any immunity from this fault; and, indeed, if the writer of a bee book only gave his own experience it would necessarily be very incomplete. I have many times put two queens together, the above-mentioned young queens among the number. They wrestle and fight vigorously, but in no instance have I seen one stung. The queens will protrude their stings, as they often do when no combat is in progress.

Again, it is said when two stocks or swarms of bees are united the queens settle the right of government themselves. This I doubt, for this summer I have mixed many lots, and after a few hours I find one queen encased by the workers in the usual manner, where she is doubtless worried to death. In one instance I caged the second queen in the ordinary manner in hopes the bees would get used to her and let her live, but after three trials at intervals of two days each the queen died of worry and exhaustion.

I am becoming very sceptical in the matter of queenly animosity one to the other, and begin to think that regicide lays more at the door of the workers than the rival queen. I recorded a case where five queens were put in a box together overnight, and in the morning four were dead. The survivor had the credit of the wholesale murder, but late experiments induce me to think that starvation had a good deal to do with it. I may also say that the queens hatched in the pocket boxes, although there were several unopened queen cells with them, showed no disposition to destroy them. It could not have been for want of time, as they were there six hours together. Now to revert to my juvenile queens.

On my return home I had three queens alive in my pocket, with which I commenced operations, first on a nucleus which I had deprived of its queen in the morning. Lifting out a comb I threw down into the midst of the bees a queen, crippled, and having some ragged remains of the pupa exuvium attached to her. With the usual rush the workers seized her, biting and tearing, but I soon found their fury was expended on the undesirable ragged skin. The queen was unharmed, soon cleaned, and at

liberty. Seeing this comb had been in my hand all the time, the bees remaining in the hive were still in the position of a queenless stock, and as I was desirous of multiplying my experiments as far as possible, I replaced the comb and took out another, on which I placed a fresh queen; this one was clean and well developed. The bees accepted her at once, feeding and licking her with the greatest affection. As twilight was now drawing nigh I replaced the comb, first abstracting the crippled queen, and then proceeded to the hive where I had left two queens in the morning. Alas! they were both gone, and the cause stood revealed by signs of the presence of a fertile worker—a patch of drone brood in worker cells, of which the poor bees in their desperate efforts to obtain a queen had converted more than a dozen into pseudo queen cells.

Now, I should be very curious to see what these abnormal cells would produce, but my friend Mr. Cheshire has sent me a similar lot, which contain unmistakable drones, although the cells are like ordinary queen cells elongated to the extent of 1½ inch. The question now arises how to get rid of this undesirable worker. Easy enough if I could find her, but know not how she is to be distinguished, and time is very scarce to-night. So in the desperate hope of a better fate I put in my last remaining virgin queen. She was well received, I left her to her destiny, and I found her all right next day and the next.

My day's experiments I felt were eminently successful, and, so far as four trials went, conclusive. I am bound to say the Yankee is right. "Queenless bees will accept readily any new-born queen presented to them;" and the question then occurred to me, What would be the fate of such a queen in a stock where there is already a queen? There is just light enough to try; so recovering the queen hatched over-night, although she has been with other bees, I withdrew a comb from a nucleus containing a queen, and put in the cripple. No animosity was shown by the workers. I then found the old queen and put her on the usurper's back. She showed no fight, but ran away, and the fading daylight prevented my again finding her, so I shut up the two queens together and left them. The next day I found the crippled queen on the ground before the hive weak but yet alive. I replaced her, but the following day she was again absent and I could not find her; probably she had been thrown out and crawled away.

I do not think I can recommend my "pocket incubator," so I shall not take out a patent for it. The air is too dry. Most of the pupæ died, and others came out with crippled wings. Where, however, the young queens are expected to emerge within a few hours the pocket will prove handy and safe, and I daresay I shall make use of it again for the same purpose. I fear my young queens have small chance of successful courtship. September is just at hand, and drones are very scarce; in one hive only have I any, and those are decreasing daily.

I had the curiosity to accurately weigh some bees, and found them to average—queens (at four hours old), 8.15 grains; drones, the same; workers, 1.25. It has struck me as curious that although I never hesitate to seize a queen with my fingers in the midst of her subjects, in no instance have I received a sting in the act, although numbers of bees often follow on my fingers. —JOHN HUNTER, *Baton Rise, Ealing.*

**CRYSTAL PALACE BEE SHOW.**—This will be on the 21st, 22nd and 23rd inst. The prizes offered by the British Bee-keepers' Association are liberal for varieties of bees capable for cultivation in England, as well as for hives and honey.

## OUR LETTER BOX.

**CANKER IN FOWLS (J. T. S.).**—The food you mention is not good enough to keep fowls in condition. There is not much in the way of food to be found in a timberyard, and sharps make but a bad breakfast. The best and cheapest way to feed is to give them slaked barleymeal or ground oats morning and evening, the house scraps at mid-day. Where birds are underfed they become weak, and are almost always attacked by some disease they have previously had, or their parents before them. The same weakness that allows it to appear prevents them from recovering. We should put all the birds that are suffering in a place by themselves. We should give to each a tablespoonful of castor oil. Feed on the barleymeal. You may slake it with strong beer for a few days. Dry all the causer thoroughly with a sponge, and dress it with powdered alum, being careful that it penetrates into the cracks. This generally cures it in a few days, but much depends on having the causer dry before the alum is applied.

**PARROTS FALLING FROM THEIR PERCHES (H.).**—Your birds are suffering from a nervous weakness, which is the cause of them falling from their perches. Parrots are very liable to the said accident, which is encouraged and brought about through being kept in a somewhat confined and warm temperature. The keeping of them in your bedroom to cure them is like pouring oil upon the fire to extinguish it. Remove the birds from the bedroom and occasionally (two or three times a-week) drench them with cold water from a watering-can, but do not repeat the shower-baths so frequently during cold winter months. After the bathing and during the time the feathers are wet spurt from your mouth a teaspoonful of brandy over the Parrot, after which throw a cloth over the cage and place it within 2 or 3 feet of the fire. When partly dry remove the cloth and hang the bird up. Accompanied with sound food this will tend to strengthen the birds. If you give your Parrots much meat partly discontinue it, for it produces laxity and weakness. Give bread soaked in milk, and a little ripe fruit just now.

**BIRMINGHAM SUMMER SHOW (W. C.).**—We have no information as to the third prize for Black Red Game pullets.

**CANARIES IN A GREENHOUSE (A Subscriber).**—As you have kept your Canaries in a greenhouse all the summer you may safely continue them there during the winter, especially as you state "provided frost was excluded." If you wish to remove them from the greenhouse do so at once, and then the birds will moult in the proper season; but if you keep them in the greenhouse (where they will moult, and probably may be doing so now) until Christmas or February and then remove them, you will tend to see being about a spring moult, and thus render your birds unfit for early breeding with. It is the changing of the birds from different positions into varying temperatures which brings about a looseness of feathers. These birds cannot be considered hardened but weak.

**DOGS AND BIRDS.**—On Tuesday August 31st I sent one of my best Partridge Cockerels to Bath in splendid condition. He returned to-day (September 4th) in a most deplorable state; one side of the breast was entirely gone and tied up with string; it was also nearly filled with feathers. The poor bird had suffered severely, as the whole of the feathers and even part of the skin and flesh had been torn from his back. Some of your readers may have noticed how he looked at the Show, as I believe the injuries were received on the journey to the Show. —CHARLES SKEWICK, *Bydlesden, Keyleigh.*

**TUMOUR ON RABBIT'S CHEEK (M. M.).**—A Guinea Pig dying suddenly and a Rabbit's face being swollen are not indications of a contagious disease. The Guinea Pig probably was overfed, and the Rabbit's face is attacked by a small tumour. Bathe it with hot water daily, and if matter is apparent open it with sharp-pointed scissors; wash the wound with tepid water, and then leave it to heal.

## REMARKS.

- 1st.—A very beautiful and pleasant day, but cloudy at night.
  - 2nd.—Dull nearly all day, and cloudy at night.
  - 3rd.—Dull morning, soon turning to rain, showery till 1 P.M.; fine afternoon and evening.
  - 4th.—Fine all day, at times very bright; but cloudy at night.
  - 5th.—Fine at 9 A.M., alternate sun and shade, but on the whole a pleasant day; and starlit night.
  - 6th.—A very bright fine day, without being too warm.
  - 7th.—Fine early, rather hazy at nine, but very fine afterwards; fine sunset, but rather close in the evening.
- A pleasant week, particularly the latter part of it, being very bright without being hot. The temperature very nearly the same as last week, but that the range was rather greater. —G. J. SYMONS.

## COVENT GARDEN MARKET.—SEPTEMBER 8.

TRADE still keeps stagnant, and goods are only cleared by taking low offers. Of hothouse fruit the supply is quite equal to the demand, but prices of Grapes will mend as soon as the glut of Jersey produce is over. English Tomatoes have made their appearance, but the crop will be light this season.

From observations taken near London during forty-three years, the average day temperature of the week is 57.6°; and its night temperature 45.4°.

## TRAINING HARDY FRUIT TREES.

INCE the introduction of orchard houses and similar structures I am afraid that the cultivation of hardy fruits has gone backward; it is a great pity if such is the case, and I would advise young gardeners to look themselves up a little in this matter, for their employers sooner or later will surely make a demand in this direction. Orchard houses are very useful structures, and to the amateur who can attend to them himself I believe they bring health, strength, and length of days; they create a taste for the purest pleasures of this life, and produce an abundance of the most harmless of luxuries. But let not the professional gardener think that orchard houses will supersede the use of garden walls, and that because he has one or two of these structures he can afford to look disdainfully on outdoor fruits. I should require some acres of orchard houses to meet my demands, and by experience I know that the produce of orchard houses is comparatively nothing in return for labour as compared with the labour and produce of well-managed outdoor trees. Moreover, though some of the fruit from the orchard house may be superior to that grown outside, the greater portion is vastly inferior. This is specially the case with Peaches and Nectarines when grown in bush form; for unless these fruits have the full sunlight on them through the whole period of their growth they are never fit to eat. For this reason, for indoor culture, the system of flat training is vastly superior to training as bushes. By well-managed outdoor trees I do not mean those trained in the most artistic forms—they are mere playthings for those people who have no better occupations—but those trained in such a manner as to produce the greatest quantity of good fruit in the shortest time. The man who would spend several years in training his trees to fancy shapes, and produce little or no fruit, looking on fruit-producing, in fact, as a secondary affair, is more fit to be a milliner than a gardener.

I believe it was Loudon who said that a man would never make a gardener who was afraid to use the knife. Things have changed since Loudon's time, and the best modern gardeners do not use a knife once where Loudon's contemporaries would have cut away wagonloads. And yet there is room for more improvement in this direction. The average British gardener has still too much liking for a good knife; he still likes to allow his trees to waste their energies by making a great quantity of useless wood to be afterwards cut away. If he buys trained trees for walls he must cut them back for a year or two in the hope of getting them into some perfect form as drawn out for him in gardening books. He may cut and he may hope, he will never realise the picture; such trees only exist on paper, and it is as well to acknowledge the fact at the outset, and make up our minds, instead of attempting impossibilities, to have the wall covered in two or three years and a good crop of fruit on it.

No. 755.—VOL. XXIX, NEW SERIES.

Fairly-trained trees of Plums and Cherries, and also Peaches and Apricots where these do well, need no cutting back at all when received from the nursery, unless the wood is not ripened, and in that case they are hardly worth having. Planted in November, and encouraged to grow in the following summer by disbudding where the shoots are not required, and training-in at full length wherever there is space to be filled—never minding whether they are laterals or main shoots, they all answer the purpose alike—average trees will always fill a wall in three or four years, and often a good quantity of fruit can be obtained the second year after planting. If the trees are at all vigorous it does them good to fruit them, but fruit should not be left on any that are weakly.

The Green Gage and Jefferson Plums will often bear nicely the second season after planting, as will also the Morello Cherry.

All wall trees require disbudding in their young stage, for having been trained in the open ground with light alike all round them, they at first make as many buds on the side next the wall as they do on the front side. Those buds next the wall if not carefully removed are sure to produce injurious results. For laying-in at full length preference should be given to those shoots produced on the upper side of the main branches; those, however, on the lower side will do nearly as well, and must be used when the space cannot otherwise be filled. Those shoots which are inclined to grow straight out from the wall should generally be kept hard pinched, and if they do not fruit they will at least shade the stems and encourage their development.—WILLIAM TAYLOR.

## TAKING-UP AND STORING POTATOES.

I AM afraid that I cannot give "BETA" the precise information he needs as to "when, how, and at what stage of growth the haulms can be pulled away from Potatoes without affecting the flavour and value of the tubers." This is a matter which it is impossible to make clear on paper in a way to suit all growers and circumstances. In my previous letter the question of pulling off the haulm was subsidiary, my primary object being to sound a note of alarm on the danger of too thickly storing newly-dug tubers.

When I speak of removing the haulm from a crop to prevent the disease, I mean that I would as soon take up the crop itself if I had time to do so before the dreaded heavy summer and autumn rains. That presupposes the tubers to have attained a useful size. I take them up or stop their growth before then is wasteful and to leave them longer, if heavy rains and close, warm, muggy weather is pending, is often ruin. In the matter of garden crops, and except for purposes of experiment, I have not had any diseased Potatoes for nearly twenty years. By growing not late varieties and continued watchfulness I feel myself quite competent to evade the murrain.

It is seldom that injury is done to a crop until the Potato plant has just passed the zenith of its vigour. If,

No. 1407.—VOL. LIV, OLD SERIES.

after that, heavy rains fall accompanied by a high temperature, disease is almost certain to follow. A rising thermometer and a falling barometer, with a glance at the telegraphic weather reports, have always afforded me timely notice of danger. When I once decide that action must be taken the work of taking up the crop or removing the haulm is prompt. I prefer to take up the crop if I have convenience for thinly storing the tubers, but if this convenience is not afforded I prefer to remove the haulm and let the produce rest thinly in the ground until a suitable time for storing.

My experience has told me that the disease seldom sets in until early and moderately early kinds have attained to nearly their full size; and when that is the case, and when a change in the weather is imminent, I take up the crop, or if time fails for this I remove the haulm, and in either case the produce is quite safe. If I cannot find an airy place to store the tubers I prefer to let them remain in the ground to set their skins.

"BETA's" "well-known fact" that the tubers are "useless for culinary purposes if the haulm is removed before the latter are ripe" is, fortunately, not a fact with me and others who have adopted the practice. I can submit Potatoes of many sacks of Paterson's Victorias which have been taken up some weeks which will equal in quality any Potatoes of the same variety which have been left in the ground to ripen. What is a fact is this—that Potatoes when taken out of the ground in an unripe state are "sad" when cooked immediately, but they eventually ripen (taking longer to do so, however, than if left in the ground to mature naturally), and are ultimately perfect in quality. How this partly skinless produce obtain new skins or their watery bulk is changed to starch I know not, but such is the fact if the tubers are stored thinly in a cool, dry, and airy place.

In the great disease year of 1872 my employer, knowing the constant immunity from disease of his garden-ground Potatoes, deputed me to make experiments in the field. The first day's haulm-pulling (two acres) was a success. On that part there were no bad tubers. In the afternoon rain fell, continuing for two days with a mean temperature of 75°. The haulm which was removed after the rain was labour lost, for the tubers became extensively diseased. Tubers, unripe and stored thickly, did not ripen, but remained "sad" for an indefinite time; those which were stored thinly in a dry airy place matured into produce of perfect quality. The produce of an infected crop taken up and stored in large heaps rotted to the extent of four sacks out of five. Another portion of the same crop left in the ground to "take its chance," and not dug until the end of November, was of fourfold greater value. Potatoes are commonly heaped large and small, good and bad, promiscuously, to "save time" and to be "sorted," it may be a month afterwards. The practice ends in both loss of time and produce. When spread on the ground at digging time is the rational time to "sort." Let careful people pick the best and anybody follow with the refuse, and although a little more time is taken in securing the crop, both time and produce are in the end saved. Store dry if possible, store thinly, store cool.

If the bulk is too large or convenience too limited for thin storing wait until cool weather sets in before storing thickly. It is not the thick heaps, as such, that engender the violent spread of disease, but the heating of such heaps. The fungus will germinate and spread with immense rapidity at a temperature of 75°, but at 50° the spread is not nearly so rapid, and at 40° it is about nil. Under any temperature moisture is an assistance to the fungus growth. Therefore it is that I repeat, Store dry, store thinly, store cool.

Thousands of tons of produce have been ruined by storing too early and too thickly—that is, by producing a close, heated, humid atmosphere in the heaps, and providing the very conditions in which the fungus luxuriates. Rather than do this I prefer to let the tubers rest in the ground in their simple natural isolation, and I am a gainer by the apparent delay. If the haulm is removed before the fungus spores have germinated the crop is absolutely safe, and if the haulm is not removed the crop is safer than if thrown together in large heaps in a moist state in warm weather.

I do not perceive the necessity of removing the haulm from late crops at this date, because I do not apprehend that a high temperature will accompany a possible fall of rain. It is the combined action of heat and moisture that fosters the spread of the murrain so disastrously; the action of either, if alone, working little if any injury.

I am afraid "BETA" will be again dissatisfied with my remarks, but I feel conscious of my inability to lay down a line

of guidance whereby the disease can be averted by all growers and under varying circumstances. Even if I were cognisant of these circumstances I might fail, and being ignorant of them my power to aid is infinitely lessened. I can only aid by giving my experience and its results, with the reasons for adopting a given mode of practice. The rest must be left to the intelligence of growers, of which I opine that "BETA" possesses a fair share.—YORKSHIREMAN.

## STRAWBERRY CULTURE.

STRAWBERRY cultivation seems to be a subject of no little interest to numerous readers, judging by the many letters of inquiry I have had since the publication of my letter of August 26th.

It seems to be quite the exception to many growers to obtain anything more than a very poor crop of fruit the first year after planting; I am therefore induced to give the details of my way of growing a crop of fine large fruit on first-year plants. Strawberries are grown better in quality, larger in size, and more independent of the season, on first-year plants than at any other time during the three or four years they usually are grown. My land is very light, and not what is considered good Strawberry soil, and I find that I can grow more fruit the first season than I can (on many sorts) by letting them fruit the third year.

I always chose land that has grown Potatoes as the previous crop in preference to any other crop, for the land is, after Potatoes, at liberty in good time, and is left in a nice mealy condition, free from slugs and other enemies to ripe fruit. On the contrary, planting after a crop of Cabbages you follow a very exhausting crop, the land often lacks moisture, and the fruit when ripe is attacked by a host of slugs which have established themselves during the time Cabbages were growing on the land.

Deep cultivation I always give my land, but a caution is here necessary. I never new trench land without having at least one year previously subsoiled it. Trench some land, and turn to the top a raw, harsh, and hungry subsoil, and you need not be surprised if the crop next following sorely disappoints the hopes of the cultivator. I have tried it on a large scale, a field at a time, with the plough, ploughing 8 or 10 inches on land that had only been used to 4 inches deep; and I have tried it with the fork in scores of instances, and the result has always been the same—hopes disappointed, a poor crop, and deep cultivation discredited. But I am wiser now if not richer for the experience I have gained during a period of nearly twenty years. I am still as great an advocate for deep cultivation as ever, and I either trench or subsoil for every crop I grow. As my land is in good heart I do not use any manure at the time of planting.

Having the land well cultivated I always wait for a good rain to thoroughly moisten the soil from top to bottom. I would rather wait a month than plant in dry soil and a hot scorching sun. In this matter it is indeed true that "patience is a virtue." If you are in a hurry to plant you will perhaps find out that "more haste less speed." I think September quite as good a month to plant in as either July or August, minding only to have good plants to plant. In September you have a better choice of situation, as many of the summer crops are ready to remove, and the cooler days and long dewy nights are much more favourable to planting than during either July or August. I plant in rows 30 by 15 inches, and the second year taking out every other plant, leaving them 30 by 30 inches for the second and third year's crop. As stated in my last my plants are raised in nursery beds, and are carefully removed, each with a mass of rootlets and soil, and to see them at the week's end you would hardly believe that they had been planted so short a time. I have my runners struck in June. I see by reference to my note-book that I began planting them in the nursery bed on the 30th of June this year. I strike my runners in each alternate row of first-year plants, gathering the fruit from every other row, and allowing no person to set a foot on the row where the runners are striking. I only allow four or six runners to a plant, taking the others away as fast as they make their appearance. After my bed is planted I keep the hoe constantly going among the plants, hoeing them over if possible at least once a week, yet never going on to the land when it is wet. It is surprising how fast they grow, and by the middle of October they look like plants a twelvemonth old.

Early in March, or as soon as the land is dry enough, having hoed them over two or three times, I give them their mulching

of rich horse or pig manure, two or three barrowful to a row of thirty plants. When the plants are commencing to bloom I bed on top of the manure with clean fresh wheat straw, completely covering the whole of the land, but minding not to cover or bury any of the leaves or flower stems. The rain and the worms flatten and fasten the straw down in a few days, and then I can go and gather splendid fruit in almost any weather.

I feel I should not be doing justice were I to close this letter without saying a word in honour of a most useful assistant I have, who takes care that no birds come and help themselves to my fine fruit. What more provoking than when you have been at all the trouble and expense to grow fine fruit up to within a day or two of its being ripe, for a set of impudent and voracious blackbirds and thrushes to come and devour and mutilate your crop? This is unbearable. The secret of my immunity from such intolerable thieves is a fine tom cat brought up in the garden from a kitten, who spends his time day and night, who has a house (a portable one) in the centre of the bed, containing sitting-room and bedroom, and a dining-room and observatory on the roof, who eats, drinks, and sleeps in his house, and during the greater part of the day prowls and stretches among the Strawberries in all sorts of strange positions—a most hideous sight to the eyes of the birds. I do not think I lost half a dozen Strawberries this season from birds, though at times I had stones of ripe fruit on the plants. Is he not worthy of honourable mention in connection with my success as a Strawberry-grower?

A few words more and I finish. I am a lover of birds—in fact of all living things, whether plants or animals, and I never destroy a bird. It is nearly twenty years since I last shot a sparrow, and as it dropped dead at my feet from the roof of the house, its beak loaded with earwigs (I counted eight), I felt that I had shot one of my friends, and determined to shoot no more.—W. LOVEY, Weaverthorpe, Yorks.

#### RAISING BLUE LOBELIAS.

For bright marginal lines of colour few plants are more popular than Lobelias. They are used in all gardens where flowers are cherished in the form of bedding plants. The plants are raised from cuttings and seed. The seed is generally sown in heat in spring, and the young plants grown on rapidly until May; but plants equally good may be produced with less care and scarcely any heat by sowing the seed now. Hundreds of amateurs have a greenhouse or cold frame who have not a hotbed or stove. Such should always sow seed of Lobelias in September, and they will have plants in May in all points equal to those of their neighbours who raise the plants in heat in spring and grow them on quickly.

The seed should be sown in rich light soil and be covered very slightly, and the pot or box should be placed in a shaded place outdoors until the seedlings appear. The soil should never be dry; and to prevent this water thoroughly before sowing the seed, and cover with squares of glass to arrest evaporation. The seed should be sown thinly, and the pans may be wintered in a frame from which frost is excluded, or in a light place in the greenhouse. The plants will be ready for pricking-out in March, and will be in fine condition for planting in May.

Thus may those who have no heated structures in spring raise their Lobelias.—AMATEUR.

#### WHICH IS THE BEST WAY TO TRAIN OUTDOOR PEACH TREES?

MR. TAYLOR'S interesting paper on this subject contains much useful matter, not only in its explanation of the details of a praiseworthy effort to overcome the difficulties arising from an ungenial soil and climate, but also because it—involuntary as I think—shows that there are rocks and breakers ahead, and that there are blemishes and imperfections attendant upon every method of the culture of these particularly sensitive exotics upon open walls.

The special merit of cordons undoubtedly consists in the facility with which by their aid walls may be covered, the quickness with which fruit may be obtained, and the ease with which failing trees may be replaced. So far I agree with Mr. Taylor, but I am totally at variance with him when he claims for cordons superiority over fan-trained trees in greater freedom from the attacks of blight or disease, the superiority

of fruit, the ripening of the wood, or even in covering the walls more quickly.

Before proceeding to discuss these points in detail it may be well to state that I, too, am cultivating these fruits under considerable disadvantages, such as a poor thin soil and a climate which, when I came into Sussex, was described to be by a very high authority in fruit culture as so ungenial as to render Peach culture in the open air a very difficult and doubtful matter. This was a kind and valuable hint, inducing an extra amount of caution and care in the preparation of the soil, and the planting and after-management of the trees. How I have succeeded must be left for others to tell, it being sufficient for my purpose to state that I have ample reason to feel contented with the condition in health, vigour, and fruitfulness of a goodly number of Peach and Nectarine trees, embracing kinds new and old, and all kept strictly to the dwarf fan form.

Let us now turn our attention to a consideration of certain important points of culture, not by any means for the sake of gaining advantage in argument, but solely for the advancement of science and the assistance of others.

1. *Freedom from Blight or Disease.*—In thinking how this may be effected the mind immediately reverts to its cause. Close observation leads me to conclude that gumming and canker arise from some injury which the bark has previously sustained. An untimely frost or day of hot scorching sunshine may inflict scalds and blisters upon the sensitive outside that in its young state is almost as delicate as the petals of a flower, and which, though unseen and perchance unsuspected at the time of its infliction, is none the less deadly and sure in its subsequent effects. The best remedy for this evil is a permanent coping board to give shelter from hailstorms and frost, and an abundant clothing of healthy foliage to protect the young bark till it becomes matured and toughened. Bruises from the trainer's hammer, tight shreds, nails driven so close to the wood that the corners inflict an immediate scar, or the ensuing season's growth swelling around the nail inevitably sustaining injury on its removal—are all causes of a diseased and perhaps ruined tree. It is evident that in this matter a gardener is very much at the mercy of his assistants; no supervision, however constant and close it may be, will avail to remedy or prevent its occurrence. Let me appeal to young men to remember this, and to assure them that the trainer's hammer and the work it does is of equal importance as the operation of the master's knife. Be honest in what you do, and strive to preserve the branches, which you train so beautifully, intact from harm at your hands. It is only bunglers who are clumsy with their tools, but I very much fear bunglers are in the majority, for I will not let myself suppose that any really earnest person could inflict injury through carelessness.

2. *Superiority or Abundance of Fruit.*—This, after all, is the crucial test. Let your trees grow wild as a Bramble bush, or be trained to the formality of a model, I care not for one form more than another; only prove that you can produce annually the greatest quantity of first-class fruit in a given space, and I will gladly yield you the palm and become your disciple. Now I have seen the "standard" Peaches at Chilwell, the cordons at Chiswick—single and double cordons—standards and pyramids in numerous other gardens, many of them laden with good fruit, but I am bound to state without the slightest reservation that none of them are at all equal to a good fan-trained tree in the quantity, and very few in the size and quality of fruit. Nor are fan-trained trees at all behindhand in earliness of cropping. I happen to have planted a few Peaches and Nectarines on January 30th, 1873, the same season as Mr. Taylor planted his first batch of cordons, and I have no hesitation in saying that for vigour of growth, condition, and quality of the wood itself, and the excellence of the fruit which they have borne, no cordons that I have ever met with are to be compared to them. Take for example an Early Rivers Peach having a lateral spread of 18 feet, and which is fully 10 feet high. But then my mode of planting and culture is also a little out of the old groove. The greatest possible care is bestowed upon the preparation of the stations; soil of a good sound staple, rich rather than poor, is provided, and even a little manure is added to that, into which the roots are expected to penetrate in the first season of growth. Great freedom of growth is encouraged, every strong shoot and lateral being laid in wherever space admits of its being done with advantage, weakly shoots and all useless growth being removed as soon as possible; by which means anything approaching to "severe mutilation" is avoided, and the winter pruning,

resolves itself more into a shortening and balancing of strong growths, and a moderate thinning of crowded shoots, than a hacking and hewing by line and rule.

8. *Ripening or Maturing of the Wood in Autumn.*—This is always done thoroughly well by the aid of the permanent wooden coping, which not only protects the wood from early frosts, but, acting as a reflector, helps to retain heat in the walls, and also by the reflection of the heat given off by the wall promotes the play of a genial temperature upon the wood. The foliage is removed as fast as its hold upon the branches becomes loosened; no branches are unfastened, and not a nail or shred removed till the time of winter pruning, which occurs early in February.

I may add that the land near the Peach walls is well drained, although not cold and heavy, and in every instance before proceeding to plant such trees in the open air due care should be taken to thoroughly drain the entire garden, not only to prevent the accumulation of stagnant water, but to elevate the temperature of the soil, and consequently that of the air, as much as possible. No doubt Mr. Taylor has given due attention to this important matter, but it is nevertheless one which must not lightly be passed over here, for I am well acquainted with more than one large garden from whence come frequent complaints of the ravages of frosts, and yet the value and importance of drainage apparently remains ignored or misunderstood.—EDWARD LUCKHURST.

## TWO PEEPS INTO A ROSE AND CLEMATIS GARDEN IN BATH.

### PREFACE.

THERE must perforce be two peeps, because the Rose and Clematis bloom at different times.

#### PEEP THE FIRST.

Two notices by my pen of Mr. Ambrose Awdry's extensive and beautifully kept rosery at Seend, Wilts, appeared some years since in this Journal—viz., in August, 1866, and again in August, 1869. Since then Mr. Awdry, owing to the continuous delicate health of a member of his family, has been obliged to live entirely in Bath. The Seend rosery has disappeared—it has not for the last six years been a garden, but a field; its glories gone, it is but as other green fields, or it may be, for I know not, as I have never seen it, that

"Where once the garden smiled  
Still many a garden flower grows wild."

Howsoever it be, the Seend rosery is but a bright memory and no more; but a man who really and enthusiastically loves anything never gives up—he is never daunted. There was a charming series of papers written years ago by "D., Deal," among the very best he ever wrote, well worthy of a reprint, which appeared, I think, in the "*Florist and Pomologist*," edited then by Robert Hogg and John Spencer, describing his gardening difficulties in his curate days, especially how he cultivated his beloved "florist flowers" when neither soil nor situation was favourable; how from this place to that place he went, still carrying with him flower taste and determination to cultivate it whatever might oppose. So of Mr. Awdry; cut off from the pleasure of a large country garden, he determined to make and enjoy one in town. Sometimes a town-dweller hires a garden with the chief object—quietly kept from his wife, by the way, of having a place for him to meet his cronies in, and that snug arbour in the corner is more prized than anything else—that arbour where day after day

"The scent of the 'hacca' it hangs round it still."

Sometimes a town garden is hired—good purposes these—for the benefit of having fresh vegetables and the healthy exercise caused by their cultivation. But if people have had a good country garden, unless they are thoroughly enthusiastic, when they come to live in town they content themselves with talking, when a peg too low, about the happiness they used to have in their garden; but that happiness is a past thing.

Mr. Awdry lives in historic Pulteney Street, one of the finest streets in England, which one seldom passes through without thinking of good old King George III. and the late Emperor Napoleon, both of whom lived in it, and its name commemorates a statesman of George I.'s reign, now forgotten save from this street. Such is the fate of statesmen—in all men's mouths while living, but when dead remembered only by two rows of houses! Mr. Awdry has fortunately been able to secure a garden within five minutes' walk of his house, which I find on the morning of 29th of June to be just a stroll from

the back of Pulteney Street past or through Henrietta Park, a sort of grassy square where some schoolboys have their cricket field, and around which are neat villas; turning along Henrietta Road I am at the garden—at least a door in a wall leading to it; a moment more I am inside, and before me a blaze of Roses. The size of the garden is about half an acre, and it is narrow, its width being much less than its length. Its situation, shut in entirely from the road, is, as seen from the inside, very pretty. The old parish church of Bathwick, long since disused, is on one side with its Willows and cemetery. The cemetery, Mr. Awdry tells me, he finds an excellent neighbour, as no thieves will cross a graveyard, and the whole garden is catproof—thiefproof and catproof, almost equal blessings to a gardener. Above, at one end, but at a considerable distance, is Camden Crescent (what a pretty shape is a crescent when you can see the whole of it at once); at the other end, a long way off up the hill, is Sham Castle. All who know Bath know it has a girdle of hills around it, and Sham Castle is on one.

On looking before me I see the plan of the garden. At the end at which I enter are twenty-four small oblong beds on grass for bedding plants chiefly. These occupy but a small space, still the green of the grass as you look along it to the Roses beyond, is in capital taste. Around the garden is a walk, with at equal distances wire arches. Down the middle is another walk and other arches, and a wire dome of some size. Then around the fence is high. Arches, dome, fence chiefly for growing the new varieties of the Clematis, the ground for Roses. No potting-shed, no compost-heap, or anything of the kind is visible, all screened off, the whole garden a fair show with nothing to take the eye from the rich display of floral beauty. I should add, that in addition to Roses and Clematis, Mr. Awdry cultivates Strawberries to much perfection.

Among the Roses that have done best this year here are La France, John Hopper, Mme. La Baronne de Rothschild, Eugène Verdier, and Duke of Edinburgh. The Duchess of Edinburgh has not done so well. Paul Neron, that huge Rose, has done well; so has Eugène Verdier and Charles Lefebvre, also the Countess of Oxford. Bath is a good climate as we all know, and this year so favourable to growth, all Roses have made good wood. Baron Gonella always does well in Mr. Awdry's garden, but not so many others until this year. All the Roses are grown either on their own roots or on the Manetti. Walking among and looking down into Roses is such an advantage. For instance: so best you see that neat and trim but not too vigorous Rose, Madame Vidot. It is pleasant to see a whole place pretty, and all—every foot used, with no spare bald places. There were in addition some grand pillar Roses standing-up in their glory.

I may just mention that the Strawberries found to suit best are President, Cookscomb, Sir Harry, Sir Charles Napier, and Dr. Hogg. Of these I can say that their flavour was admirable. Walking through the Roses, examining choice blooms, taking general views of the garden from different points passed the time away pleasantly until the time to spare was gone, and I passed out of the door and the pretty garden was seen no more. "Now," said Mr. Awdry, "you must come and have a second peep at my garden when the Clematises are out."

#### PEEP THE SECOND.

Now, August 27th.—Again I enter, and what a change of floral beauty. The Roses are gone save here and there a few blooms. No more Baroness Rothschild, which somehow will catch the eye more than any other Rose. The twenty-four beds on grass as you enter are now bright with Asters, French and German; also dwarf Victoria Asters, which bear looking into. How different are the French and German Asters! the former showy in the extreme, the latter neat in the extreme, particularly those having a white centre. The other beds are ablaze with Verbenas and Calceolarias. Of course, the great difference I see in this garden since my first peep is that the boards around, the arches over, and the wired dome, a very conspicuous object, are now bright with Clematis. As yet certainly the general colour of different varieties of the Clematis is, well—purple or violet. Upon a near inspection one sees differences, but at a distance they resemble each other, save that here and there is a white. What is wanted is another decided colour, a crimson or an orange; but while saying this I am far from depreciating what as yet we have. Then, again, what a gain it is to have a perfectly hardy flower, vigorous in growth, abundant in bloom, and the blooms very large, and

coming at a time when so much wanted. The Clematis is such a showy flower, such a contrast to the Passion-Flower, which must be looked into; but does it not reward us for that close in-look? yet it can never make a gay garden. Mr. Awdry's garden was just as gay in August with Clematis as in June with Roses. Of course there was Jackman with its violet purple flowers; Lady Caroline Neville, French white; Jeanne d'Arc, greyish white; Otto Frobel, the best of all the whites; Gem, lavender; Star of India, which on a near look has reddish bars; William Kennet, Tunbridgensis, lavender and mauve; Alexandra, reddish violet; while Mrs. James Bate-man has pale lavender charms, and many others. Here and there a wandering Clematis had caught and clasped round a spray of Rose.

My readers can well imagine how the empty high black boards became changed into a Clematis wall, and how wire arches and wire dome became Clematis arches and Clematis dome. Mr. Awdry has various plans for covering his boundary fences. Thus where neither Rose nor Clematis does well, he has the double-blossomed Syringa. Then he indulges in a lesser way with another love—viz., Pompon Dahlias, which being small enough for a buttonhole or a bouquet, are Dahlias from which all coarseness is gone completely.

Such is a brief account of this interesting and very gay garden. What a good thing it is when a man can make a garden his hobby. Scarcely any other so much promotes health or gives so much pleasure; while, perhaps, it gives more pleasure to others and to a greater number than any hobby whatsoever.

How in such a sweetly quiet garden as this a man may banish his cares, and get more power to bear them, for a garden refreshes the spirits. "Happy," said the poet Gray, "are they who can ere ate a Rose or erect a Honeysuckle." Says Archbishop Saneroft of his garden in Suffolk, "I trust no other hand but my own to do the nicer work, so long, at least, as my health will allow me to enjoy so pleasing an occupation; and, in good sooth, the fruits taste more sweet and the flowers have a richer perfume than they had at Lambeth." And as these felt so others may and do feel; and I think, as in poultry, a man is more successful if he sticks to a few varieties, so in gardening. Thus, for instance, as in this case of Mr. Awdry and his culture of the Rose and Clematis.—WILTSHIRE RECTOR.

## GREAT INTERNATIONAL FRUIT AND FLOWER SHOW.

EDINBURGH, SEPTEMBER 15TH.

[SPECIAL TELEGRAM.]

It asked, What has contributed to the success of this great Exhibition of garden products? we must not look for an answer only to able management, business enterprise, and cultural skill, nor to natural advantages of site, soil, and climatic influences, but also and especially to national feeling—Scots strive to have Scotland in the front; they succeed, and especially in aiding the soil to yield superior examples of the most useful of all luxuries—fruit. The national aims in fruit culture are worthily ambitious. The standard of perfection is a high one, and as each grower is emulous of another's fame this standard is aimed at by all, and is attained by not a few. The Exhibition, therefore, which is now being held in the Music Hall and Assembly Rooms is an expression of the united efforts of an united people, spread in one of the most beautiful cities of Europe in a manner by which not only the city may be satisfied, but of which the United Kingdom may be proud. Neither are these results achieved alone by the growers of the fruit, but they are aided by the owners, who in not a few instances have permitted that preparations should be made for a great endeavour involving, if needful, an immediate sacrifice for the realisation of an ultimate triumph. Gardeners, wherever situated, who are continually working under high pressure in providing to the utmost for consumptive demands—who are ever striving to produce a maximum quantity combined with fair quality, may be dissatisfied with their efforts in comparison with the high-class productions specially grown and provided for a great occasion. But they need not be. Owners who annually tax the powers of their trees, and Vines, and men to the utmost for their daily wants may deem their produce of immoderate quality as judged by the splendid prize fruit which is here exhibited. But they should not so judge, for it were as fair to compare the speed of their hacks and carriage horses with that of the specially prepared and thoroughly trained racers. It does not detract in the slightest degree from the skill of the cultivators of the fine fruit which we are now noticing to remember that much of it has been specially prepared for a specific object. In the matter of Grapes, for instance, it is not to be disputed that on both sides of the Tweed old Vines have been reared for a con-

centration of their resources for a given time and purpose, and new Vines have been planted with special calculations that they should attain their first flush of vigour at the time of this great Show. That these Vines have done what was expected of them sufficiently attests the skill of the growers, and also, it may be said, the patriotism of their owners. Both have been laudably jealous of the fame of the fruit-producing powers of their districts, and hence the gratifying results of a combination of will on the part of the masters, and skill on the part of the men.

This Show is great in aims, objects, and results. The schedule is comprehensive, the prizes liberal, and the management of the most practical kind. Almost all ranks and classes have cast their mites into the common treasury, and the result is that the noble sum of £700 is provided for prizes. Fruit is divided into four divisions of ninety-five classes, and the plants, &c., into a similar number of divisions and fifty-three classes, making a total of 148 classes, besides special prizes offered by Messrs. Sutton & Sons, Reading; Mr. Munro, Potters Bar, London; and Scottish patrons. The schedule is in many respects a counterpart of that of the Alexandra Palace Fruit Show, but with important additions and a sensible increase in the amounts of the prizes in some of the divisions. For collections of fruit the amount offered is £86, for Pines £27, and for Grapes (Scotland is a land o' Grapes as well as a land o' cakes) £168; for foreign competitors £120, with minor prizes for other products. Liberal prizes were also awarded for plants and flowers, the most noticeable being £25 for ten stove and greenhouse plants, and £18 for six plants in flower. For most of the prizes there was good competition, and some admirable examples of culture were staged. The Grapes, as may be expected, were the finest feature of the Show, and the weights of the large bunches were scanned with the greatest interest. We announce at the earliest possible moment the successful exhibitors of this important Exhibition, reserving to our next issue a more complete and detailed report of the gathering. Our northern friends sustained their reputation for the hospitality and friendliness which they invariably extend to all visitors.

As an instance of the energy and promptitude of the Committee in completing the arrangements of the Show the staging was done during the night, in order that the Judges could commence their duties at 8 a.m. this (Wednesday) morning. The principal awards were as follows:—

Some prizes of the greatest and best fruit Exhibition ever held. First comes the battle of the giants. Noble contest. Unparalleled achievements. In White Grapes Mr. Curror, Eskbank, is first with Calabrian Raisin, weighing 26 lbs. 1 oz.; Mr. Dickson, Arkleton, second with Syrian, weighing 25 lbs. 10 oss. These are honest well-shaped bunches with good berries, Mr. Dickson being the largest, but has lost by over-thinning; it is 8 feet in circumference and 2½ feet long.

For heaviest Blacks Mr. Hunter, Lambton Castle, is first with a seedling from Gros Guillaume, weighing 14 lbs. 11 oss.; Mr. Dickson being second with Black Hamburg, weighing 9 lbs. 8 oss. For light varieties of Grapes Mr. Hunter, Lambton Castle, Mr. Johnston, Glamis Castle, and Mr. Reid, Rockfield, stand in the order named with grand collections.

For four varieties Mr. Landen, The Quints, Salop, Mr. Bruce, Chorlton, Manchester, and Mr. Whytock are the winners. For two Black Hamburgs Mr. Johnstone, Mr. Jones, Wynyard Park, and Mr. Fraser, Stobo, are successful.

For Muscat Hamburgs Mr. Dickson, Mount Melville, is first, and Mr. Spiers, Golgarburn, second. For Madresfield Court Mr. Bruce is first; Mr. Potts, Manley Hall, Manchester, second; and third, Mr. Fraser. For Black Alicante (grand), first, Mr. Hunter; second, Mr. McConnochie, Cameron House; and third, Mr. Curror. For Gros Colman Mr. Upjohn, Worsley Hall, is first, and Mr. Jones, Wynyard, second. For Lady Downes' Mr. Greig, Craigend, is first; Mr. Fraser, Raohan, second; and Mr. Reid, Rockfield, third. For any other black variety Mr. Stewart, Innerleithen (Black Prince), is first; second, Mr. Hunter (Seacliffe Black); and third, Mr. Bruce, Chorlton (Gros Guillaume).

For two Muscat of Alexandria Mr. Johnstone is first, Mr. Stewart second, and Mr. McConnochie third; and for any other White Mr. Curror (Calabrian Raisin, 10 lbs.), is first, Mr. Greig (Buckland Sweetwater) is second, and Mr. Jones (Trebiano) third. For single bunches of Black Hamburg the winners are Mr. Jones; Mr. Goldie, Trochrague; and Mr. Hannah, Burnhead. For Alicante Mr. Fraser, Raohan House, is first; Mr. Hannah second, and Mr. Curror third. For Muscat of Alexandria, Mr. Stewart and Mr. Greig. For best-flavoured Black, Mr. Dickson, Mount Melville (Muscat Hamburg), and Mr. Jones (Black Prince). For Whites (flavour), Mr. Methven, Blytheswood, and Mr. Greig. For finest bloom, Mr. Curror with Alicante. For best basket of Black, Mr. Brown, Kilmarnock, and Mr. Service, Dumfries. White, Mr. Bruce, Chorlton.

In Division 2, for two bunches of Black Hamburg, Mr. E. Grossar, Ireland; and Mr. Stalker, St. Roque. For Alicante, Mr. Goodhall, Donisla House, and Mr. Dempster, Edinburgh. For Lady Downes', Mr. Brunton and Mr. Stalker. For Muscat of Alexandria, Mr. Goodhall and Mr. Stalker. For Alicante,

Mr. Goodhall and Mr. Simpson, Wortley. For single bunches of Lady Downes', Mr. Brunton and Mr. McIntyre, Kingmuir. For Muscat of Alexandria, Mr. Goodhall and Mr. Stalker; and for any other Black, Mr. Brunton and Mr. McIntyre.

For the silver cup offered by James Boyd & Sons for six varieties are three splendid collections, Mr. Stewart, Innerleithen, being successful. The Grapes, of which there are about 450 bunches, are a grand exhibition in themselves. For collections of fruit (sixteen varieties), the winners are Mr. Johnson, Mr. Stewart, and Mr. Ingram, Alnwick Castle. Twelve varieties, Mr. Upjohn, first; Mr. Dickson, Mount Melville, second; and Mr. Cooke, Holeyn Hall, third. Twelve varieties, Mr. Robertson and Mr. Shand are successful. These collections are very fine.

Peaches are an admirable display of (for twelve), twenty-six competitors. The winners are Mr. Leyden, Whitehill; Mr. Donald, Kinfauns Castle; Mr. Brown, Birkwood, and Mr. Jack, Battle Abbey. For six fruits, Mr. Brand, Courton House, first; Mr. Sharp, Pitfour Castle, second; and Mr. Brown, third.

Nectarines, for twelve (twenty competitors), small, except winners, Mr. McLean, Gosford, first; Mr. Jack, second; Mr. Loudon, Quinta, third; and Mr. Speirs, fourth. For six fruits, Mr. Cooke, first; Mr. Fowler, Springfield, second; and Mr. McLean, third.

Apriots (small), Mr. Gibson, Vogrie, is first; Mr. Harper, Dundas Castle, second; and Mr. Thomson, Alnwick, third.

Pines are not numerous, but very full. For two Smooth Cayennes the awards go to Mr. Stewart, The Glen, Innerleithen, and Mr. Ingram, Alnwick Castle. For Charlotte Rothschild Mr. Miles, Wycombe Abbey, has the premier award. For Queens Mr. Sandford, Underley Hall, and Mr. Ingram stand in the order named. Mr. Stewart also exhibits nine fine fruit of splendid quality.

Melons are an excellent show. Of forty fruit, Green-flesh, Mr. Mansell, St. Leonard's Park, is first; Mr. Weir, Kirse House, second; and Mr. McFarlane, King's Meadows, third. Scarlet-fleshed, Mr. Methven, Blytheswood, first; and Mr. Kettles, Archerfield, third.

Of baking Apples there are fifty very fine collections, Messrs. Cooks & Co., Donnington, taking first honours. They are also first for heaviest Apples. The winners in dessert Apples are Mr. Culton, Mr. Kerr, and Mr. Jones.

Of Pears (very fine) there are twenty collections of twelve sorts, the winners being Mr. Ingram, Alnwick; Mr. Smith, Bargany; and Mr. Anderson, Oxenford Castle. For Jargonelles Mr. Brunton is first; Mr. Patter, second; and Mr. Goodhall third. Successful for this fruit also are Messrs. Dickson, McLean, Fairgrieve, Barry, and Mitchell.

For Bananas Mr. Fortune, Castlemilk, is first, and Mr. Brown, Kilmaroon, second. For collections of tropical fruit Mr. Leslie, Munchees, is first, and Mr. Brown second.

Gooseberries and Currants are splendid. Messrs. Brown, McFarlane, and Beck being the principal prizetakers.

Vetch's memorial medals and prizes were awarded to Mr. Reid for the best bunch of Black (Mrs. Pince) Grapes, Mr. Johnson for the best Muscat of Alexandria, and Mr. Orrror for Calabrian Raisin. To Mr. Shearer, Grassmount, for the best Orchid, Mr. Mathieson for the best stool, and Mr. Todd for the best greenhouse plant.

Plants are numerous and fine, Mr. Patterson, Milbank, taking the principal prize for ten specimens, Mr. Todd being second.

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

**DION EDULE.** *Nat. ord., Cycadaceae. Linn., Dicotyl. Dodecandria.*—"For greenhouse decoration this remarkable Cycad is at once the most easily cultivated, effective, and on account of the flatness of its rigid fronds, the most easily of its class kept free of that pest of Cycads, the scale insect. It is a native of Mexico, where it is said to be found in various provinces, and has been in cultivation since 1848, when it was brought from that country by a Miss Lavater, who presented a plant to the Horticultural Society.

"Dion edule has been cultivated at Kew almost ever since its introduction into Europe, and thrives both in the cool end of the Palm house and in the octagon of the temperate house, forming a trunk 3 to 4 feet high and 8 to 10 inches in diameter. The spread of the crown is 8 to 10 feet, and contains as many as fifty fronds, each 4 to 5 feet in length and 6 to 9 inches in breadth. Both sexes come frequently, the male come varying from 9 to 12 inches in length, the female from 7 to 12 inches.

"The seeds of Dion are eaten by the Mexicans, both the fleshy testa and the albumen, which latter in other Cycadæ is full of a starch that affords an excellent arrowroot."—(*Bot. Mag.*, t. 6184.)

**PRIMULA PARRYI.** *Nat. ord., Primulaceae. Linn., Pentandria Monogynia.*—Flowers reddish purple. "Except perhaps the *P. japonica* this is the handsomest Primrose ever intro-

duced into this country. It was discovered about 1860 in the Rocky Mountains of the Colorado district, always on the borders of alpine streams near the snow line, flowering in July, where it gives the name of "Primrose Creek" to one of the affluents of the Colorado River, in about lat. 37° N. Since that period it has been discovered commonly in alpine and sub-alpine spots in Nevada, in the E. Humboldt range, Clover Mountains, Gray's Peak, and Mount Lincoln, ascending to 18,000 feet altitude. *Primula Parryi* was raised and flowered by Messrs. Backhouse of York in May of the present year."—(*Ibid.*, t. 6185.)

## PRUNING FIG TREES.

WHEN Figs are grown in heat, and those sorts selected which bear only an autumnal crop, it has been recommended to cut the trees into shape at the end of the season, as they will break in the spring from dormant buds. It takes time, however, for these dormant buds to rouse themselves, and I find it better practice to cut-back the shoots to two leaves as soon as they become denuded of fruit. These leaves will remain on another month, and will employ their time in forming a bud in the axil of the upper one. Thus considerable advantage is gained in the spring. If any shoots do not show fruit in summer after having been pinched they are cut-back at once, and make either strong buds or fresh shoots. In the autumn I like to see on the trees a few stubby shoots which have never been stopped, and have a natural terminal bud. These in spring start first and excite the roots, which in their turn stimulate the other parts of the tree.—G. S.

## OLDLANDS HALL,

THE SEAT OF ALEXANDER NISBETT, ESQ.

BETWEEN the readers and writers of the Journal a vein of sympathy exists to a more than ordinary extent. It is not easy to determine why it is so, but the fact has been demonstrated in a hundred ways. A contributor to the pages of this paper has only to make himself known wherever he may be, and shelter and hospitality is offered him, and he is made, like the publication which has preceded him, a welcome guest. Probably this feeling is engendered by the fact which is ever manifest, that there is a willingness on the part of all who essay to do so, to convey information in a manner to be the most useful to the recipients, sparing neither time or details, however simple these may be, in accomplishing what is the mutual desire of both.

I am about to be the medium of making one whose name is familiar still better known, if possible, to the many who have profited by the details of his practice, who have been stimulated by his precepts, or interested by the happy expression of his communications. Mr. Luckhurst has frequently shown himself in the Journal, I will now try to show Mr. Luckhurst at home.

His home is in a wood on the confines of a wild forest in Sussex, and one has only to see what he has done and fraternize with him in the discussion of congenial topics to find that he is one of the most able and accomplished gardeners of the day. In five years by extraordinary perseverance and a combating of difficulties and overcoming them he has converted a peison-impregnated soil, a worse than a wild waste, into a garden of extraordinary productiveness. The walls, which have only been built within the time mentioned, are—at least the south wall—covered with Peaches and Nectarines from base to apex, with not one insect on the trees, but thousands of fruit. The ground, which then would not grow Potatoes, Globe Artichokes, nor even Horseradish, owing to its impregnation of iron, is now growing Raspberry canes 8 to 10 feet in height and other crops in the same order of luxuriance. I can say it, as the results of no inconsiderable experience with gardeners and their duties, that not many men could have done what Mr. Luckhurst has done at Oldlands in so thorough and systematic a manner. The work that he has been called upon to do, and has done it in a manner to secure the approbation and confidence of an able and critical employer, is a proof that something more than donning a blue apron, potting a plant, and using a garden implement are amongst the requirements of a skilled gardener. Young men may well note what has here been done, and the way it has been done, and judge how far they are able to carry out similar duties which they may be called on to perform.

First, then, it is noted that five years ago the place was a

wood or a waste. Not only was there not a cultivated flower or vegetable, but there were no fruit trees, even no roads. The mansion was in course of erection, and timber had been cleared for its site and for access to the works. Beyond that was nothing but an almost impenetrable jungle. This must be converted into pleasant drives, with the usual ornamental and useful adjuncts of a gentleman's residence. The wood is something like a hundred acres in extent, and is boldly undulated: here a streamlet, there a precipitous bank, and now a ravine. The first of Mr. Luckhurst's duties was to make a careful survey of the place and transfer it to a map, showing every irregularity of surface, the heights and gradients of the declivities, and the nature of the streams. This was done in a systematic manner preparatory to making the drives and walks. This has been a formidable work, for it has been done with a regard to a saving of all the possible expense consistent with a preservation of the best natural features of the estate. These could only be ascertained by taking the views from the tops of trees, so dense was the underwood and irregular the surface. Mr. Luckhurst has planned and carried out the work of road-making with great success. In one part deep cuttings have been necessary, in another uplevelings of great bulks of material. In this work the cubic contents to be removed were ascertained with accurate estimates of the cost of the work furnished. It has been the same in pond-making, fencing, and erections of all kinds, of which Mr. Luckhurst has been, as it were, architect and contractor, having furnished drawings and estimates previous to commencing every portion of the work. As may be expected, a perfect system of drainage is carried out to take away superfluous water, and, what is not less important, a system for a supply when wanted is brought within reach of the crops, Mr. Luckhurst having so arranged matters that the sewage, commonly regarded as waste, is pumped up to tanks in the kitchen garden, and to this in a great measure is to be attributed the luxuriance of the vegetables and the rude health and sturdy vigour of the fruit trees.

Thus nothing has been done by guesswork, but everything has been carried out in a skilful and systematic manner.

The principal charm of Oldlands as a residence consists in its wild woodland walks and the great natural beauty of the landscape. In an artistic and gardenesque view there is nothing remarkable to note. The treatment of the grounds is admirable, but time is necessary to perfect the plans, and the new work which is continually in progress prevents the place, as a whole, having a finished aspect. The family being also absent two-thirds of the year, it is only at stated intervals that a polish is given to the home-surroundings. Flower gardening of a high order is, therefore, not attempted. The design of beds is effective, and the borders are rich in flowering shrubs. The walls of the mansion are being clothed with attractive plants, which I will not enumerate, but leave Mr. Luckhurst to tell us what is suitable for this purpose of decoration. Yet I must not omit to say how fine is *Berberidopsis corallina*, not only as a south-wall climber, but for the usefulness of its pendent crimson wax-like clusters for drawing and dining-room decoration. When the hundreds of Conifers have increased in size, when the thousands of *Rhododendrons* are perfected, and when time is found to "trim and make neat," then will the natural charms of the place be supplemented by ornamental appendages tastefully disposed. Striking objects in the garden are dense bushes of *Hydrangeas*, their hundreds of gigantic blooms being, by the action of iron in the soil, of a rich deep blue.

I will now glance at the useful department of this place. If Mr. Luckhurst amidst his multifarious duties of planning and carrying out new work cannot find time to devote attention to many details which he would wish to do, he wisely determines that, whatever is left undone, the fruit trees shall not suffer neglect. The collection is extensive, about eight hundred trees being under systematic pruning, embracing all the best sorts. The growth and condition of these trees is little short of marvellous considering the time they have been planted, and they afford incontestable proof that the attention they have received is of the first order in tree culture. That the word "marvellous" is not an exaggeration I will instance a *Bellegarde* Peach tree on the south wall. It was received from a nursery a small plant three years and a half ago, and it has now a spread of 24 feet, covering every inch of wall from top to bottom, and is laden with fruit. Pear trees which were planted at the same time in a small state are now perfectly formed pyramids 10 feet in height, and studded with fruit spurs to their centres. Plum trees there are of the same age

and size wreathed with fruit, also Cherries and Apples. Need it be said that Mr. Luckhurst is no advocate of early root-pruning and rigid summer-pinching? Light, liberty and cleanliness, good food and careful guidance, are his landmarks in fruit-tree culture.

But it may be surmised that the soil of this garden is naturally suited to the growth of trees. This is not so, and, paradoxical as it may seem, it is because the natural soil was so bad that these trees have been made to grow so well. It was because Mr. Luckhurst was told, on high authority, that Peaches would not flourish in the open air that he determined to make them, and to accomplish that the old soil was removed entirely and new soil introduced. This soil-removal has been a work of great magnitude, for thousands of loads have been carted a considerable distance, and now the fruits of the labour are to be seen in splendid trees and luxuriant vegetables. The orchard trees were all planted on stations of fresh soil 6 feet in diameter and 3 feet deep for each tree, and hence their ruddy health and great promise.

In Peach-growing Mr. Luckhurst is not afraid of strong wood; indeed his aim has been to produce it as strong as possible, or he would not have covered a wall 10 feet high in three years and a half with fan-trained trees. So long as the growth is regular the stronger the better, would seem to be the principle of action here. As an instance of the luxuriance of the trees, the leaves of *Lord Napier Nectarine* are 9 inches in length and 2½ inches in width. But what of the fruit? The tree is laden with them, many exceeding 7 inches in circumference, and some of them taking honours at the great Show at the Alexandra Palace. In the case of these strongly grown Peach and Nectarine trees their vigour has not detracted from their fruitfulness, but has increased the size of the fruit. Ceyling boards project over the wall 15 inches, and they are never taken down. The trees are watered with sewage to keep them healthy, and syringed with pure water to keep them clean; and fruit is supplied in abundance from the second week in July from *Early Beatrix*, to the end of October from the *Late Admirable*. Dr. Hogg Peach is fruiting freely; it is a handsome fruit of superior quality. I cannot give an estimate of the varieties of fruit; that may well be done by the grower, for assuredly he is well able to furnish reliable information on the cultivation and merits of the best varieties of wall and orchard fruits.

But in this general glance one speciality must be noted in a wall of Pear trees. It is a happy idea, and will be an ever-growing source of interest. On an eastern aspect is planted a collection of Pears to be trained as diagonal cordons. The arrangement is this: At the extreme end is planted the earliest known Pear, followed by the next in succession, and so continued until the other end is reached with the latest sort. In this plan is embraced upwards of seventy varieties. The arrangement has been made with great care, and the trees are very promising.

Vines are grown in two spacious and well-constructed houses. They are also vigorous, fine in bunch and berry; and while the *Muscats* are beautifully finished, the *Hamburgs* do not quite satisfy the grower. *Royal Ascot* is carrying a fine crop, capitally finished and of splendid quality, and *Gros Guillaume* is heavily laden with noble fruit. Heavy surface-dressings of manure are applied to the border, and into this feed the spongioles are darting in all directions and adding vigour to the canes and fruit. Surface-dressing of the soil with manure is carried out with various crops with the very best results. For fruits especially, in Mr. Luckhurst's estimation, it has quite superseded the practice of digging-in.

Cucumbers are grown in a fue-heated pit, as also are plants for table decoration. In this pit a late crop of *Tomatoes* are also ripening. These and the Cucumbers are grown in strong clay, but it is first burnt and then soaked with sewage, and the vigour of the plants proves how well this strong food suits them. Melons are grown in dung beds, so that we observe two old-fashioned appliances—dung beds and fue-heating—turned to profitable account in this new garden.

I will summarise the cardinal means which have transformed a wild wood into a complete and fruitful garden. They are careful calculation, skill, zeal, plans prepared on sound principles, details carried out with thoroughness, and—for this is worthy of especial mention—sewage.—A VISITOR.

**HENDER & SONS' SEEDLING PETUNIAS.**—We have before us fifty flowers of these seedlings, each a distinct variety, each

large, and each strikingly and beautifully coloured. We never before saw such a group of *Petunia* flowers.

#### CARYOPHYLLUS AROMATICUS.

This is a commercial plant of considerable importance, and has been known to this country for nearly a century. It is only cultivated in choice and botanical collections of plants, where it flourishes in a soil composed of loam and peat, and must have a high steady temperature. It is propagated by cuttings inserted in sand under a bellglass. But while we speak of it and know it as a plant in our artificial mode of growing it, yet in its perfected state it is a tree of which the clove spice of commerce is the dried flower buds. Dr. Hogg in his "Vegetable Kingdom" states that the Clove is a tree 20 to 40 feet high, a native of the Moluccas, but now cultivated all over the East Indies where situations favourable to its growth can be obtained, and also in some of the West India islands. The cloves of commerce are the unexpanded flower buds, the corolla forming a ball on the top between the teeth of the calyx. They are first gathered when the trees are about

the prizes amount to upwards of £100. Entries close on the 20th.

#### PEACH BUSHES.

I noticed a few days since that Mr. Rivers of Sawbridge-worth had sent to London ripe Peaches of the Early Beatrice grown on a bush outdoors. I think it possible that in many parts of England the Peach may be grown and ripened on bushes. For some years I have had the Early York so grown, and it generally bears well. This year I have gathered more than six dozen well-coloured fruit of excellent flavour. I have also Crawford's Early very fine on a bush with large and good fruit. I shall try the Early Beatrice, the Prince of Wales, and one or two others. I have no wall, so rely solely on bush-growing also for other fruits. My land is high up, and bleak in winter, yet I generally have good crops; the only drawback being the number of bullfinches that eat out the bloom buds and do more damage to me than the frosts ever do. Perhaps others will try a few bushes of different sorts of Peach out of doors and give their experience. Mine are planted amongst the shrubs and used as ornamental trees, as I do also my Pears and Plums, and they have a very pretty effect both when in bloom and also when covered with bright high-coloured fruit; besides which I save the labour and expense of wall-training.—HARRISON WEBB, *Weirleigh*.

[We had a seedling Peach tree trained as an espalier in a garden on a southern slope near Witham in Essex. It ripened its fruit annually.—Eds.]

AN AGAVE AMERICANA is now in flower at Siebold's Holme, Wisbech; it stands in front of the house bordering on the street, and first showed for bloom about the 15th of May last. Its stem has reached 17 feet, and the twenty-five clusters of flowers are of a brilliant chrome yellow. The plant is known to be above eighty years of age. It was last year reported, which is supposed to have thrown it into flower.

#### OLLA PODRIDA—A CONTINENTAL TOUR.—No. 4.

FROM Milan we went to Venice. As Venice is quite a city *sui generis* built on the sand dunes of the Adriatic, and as the streets are all turned into canals, and the locomotion effected by gondolas instead of voitures, it is hardly fair to expect any public gardens; and yet Venice has a public garden on the extreme north-east point of the city, and a botanic garden near the railway station. I paid a hurried visit to the latter during a heavy fall of rain, but was much better pleased with it than the one at Milan. There was a very fine collection there of Yuccas and Agaves grown in pots, and shaded from the sun by being grown under double span sheds, covered with Bamboo mats. This species of Bamboo, nearly allied to the *Arundinaria falcata*, is much used in different ways for shading. I first noticed it in Milan, split and cut into lengths like tile laths, nailed against the sides of scaffolding poles to form a protection for workmen against the scalding sun, and also to prevent pieces of stone, or brick and mortar, from falling into the streets. It is also used nailed across windows to prevent plastering of walls from drying too fast and cracking. The smaller and finer ends are again made into blinds, by having cord twisted in and out between them, having much the appearance of fine straw. These blinds admit the air, but form a very perfect shade, and are very durable.

The Agaves and Yuccas at the Orto Botanico at Venice were growing under blinds made of the coarser Bamboo, which could be rolled up at pleasure. The collection was a very good and varied one, and the plants seemed to rejoice in their treatment. I have heard of Orchids in India being grown much in the same way in houses lathed-in with split Bamboos, and covered on the sunny side with leaves of the Sago Palm. One of the most striking Yuccas was *Yucca quadricolor*. There were also a nice collection of Roses, including many of our best sorts, and some, too, of the older varieties, which I had not seen for some time, and a very large kind of yellow Banksian; but the climate was too hot, and the petals of the Roses were too thin, as if they had been forced too much into growth. There were also some good specimens of *Acacias* and some plants of *Heliotrope* which promised to be very fine. However, the rain began to come down in torrents, and as the gondola was in waiting outside I had to hurry back through the gardens.

The public garden at the north-east end of the city is very

Fig. 52.—*Caryophyllus aromaticus*.

six years old, and are either collected by hand or beaten with reeds so as to fall upon cloths which are placed under the trees to receive them, and dried either by fire heat or in the sun. The fruit, which is a dry berry, also possesses a very aromatic taste and odour. The use of cloves in domestic economy is well known. Water extracts the odour of cloves, with comparatively little of their taste. All their sensible properties are imparted to alcohol; and the tincture when evaporated leaves an excessively fiery extract, which becomes insipid when deprived of the oil by distillation with water, while the oil which comes over is mild. Oil of cloves is obtained by distilling cloves with water, to which it is customary to add common salt in order to raise the temperature of ebullition; and the water should be repeatedly distilled from the same cloves in order completely to exhaust them.

AT THE INTERNATIONAL POTATO SHOW to be held in the Alexandra Palace, Muswell Hill, September 29th and 30th,

devoid of interest, and certainly very devoid of plants. There was a crop of hay being secured by a set of idle Italians; though when I speak of its being secured by them it is rather a figure of speech, as they were one and all lying down under the trees for the midday *siesta*. There is also the unfailing *Café Ristoranti*, or rather two of them, one at each end of the garden—one raised on a mound of earth, apparently mud dredged out of the Adriatic. There was no attempt, as I said, at flowers, and very little at flowering shrubs; but there were some nice *Acacias*, and another tree which I did not know, and which I have not yet learned the name of, which was in full flower and very sweet-scented. The flowers are in drooping racemes, white, with a purplish throat, each flower nearly an inch across when fully expanded. I saw it elsewhere afterwards—as at Verona, Bellagio, and Lugano—but never learnt the name. I need not detain your readers longer with Venetian gardening. Nor was there anything worthy of note at Verona, which was the next place we went to, except a beautiful avenue of *Cypresses*.

From Verona we went to Bellagio on the Lago de Como, and here the luxuriance of the foliage was very striking. There are two villa gardens here exceedingly well worth seeing—the Villa Serbelloni, where there is a dependance belonging to the *Hôtel Grande Bretagne*, and the Villa Melzi. The grounds of the Villa Serbelloni are very extensive, comprising the wooded knoll and point projecting into the lake, commanding views of the three arms of the lake. On one side the winding paths are cut into the face of a rock looking perpendicularly down into the lake a height of 400 or 500 feet. The whole of the wooded knoll is intersected with paths, with a circuitous driving road, by means of which you can drive by an easy ascent to the top. All the shrubs and many of the best kinds of Pines and Firs seem to luxuriate; and against a wall facing south beneath the villa were two or three beautiful plants of *Mandevilla suaveolens* just coming into full bloom. In some of the sheltered nooks were beds of *Agaves*, *Yuccas*, *Aloes*, *Dracenas*, &c., and in the woods were a great variety of Ferns. The winding paths command at different points the finest views of the lake, and this is the only point where all the three arms of the lake can be seen to perfection. Nothing was more striking than the exceeding verdure of the sides of the hills with the fresh foliage of all the trees which had not as yet suffered from the summer's sun.

The grounds of the Villa Melzi are private, but are shown to the public by payment of a fee. They are close upon the margin of the lake, and equally with the grounds of Villa Serbelloni display great luxuriance of foliage. There was a better attempt here at lawns; but with the usual fault, the grass not being mown more than once in three or four weeks. The following plants and shrubs were doing well:—*Araucaria excelsa*, *Cocos coronata*, *Chamerops excelsa*, *Abies pendula*, a beautiful specimen of the Weeping Fir; *Pinus lanceolata*; *Salisburia adiantifolia*, a very striking plant; *Justerenia violacea*, *Lagerstrœmia regina*, &c. This, which I had only seen before as a denizen of our cool stoves, was quite a large tree, both here and at Villa Serbelloni. The *Benthamia fragifera*, with its yellowish-white cross-shaped flower, was also very conspicuous. The *Bambusa gracilis*, and *Arundinaria falcata*, and other plants of the Bamboo tribe seemed to be much at home in shady places by the water side; and plants of *Sanchezia nobilis* plunged in pots had, the gardener told me, done well last year, though they had only just been put out then. The Oranges, Lemons, and Pomegranates were also flourishing; and though one of our first-class English gardeners would have made much more of the great opportunities presented by soil and climate, yet the exceeding luxuriance of the early spring growth on the trees and shrubs made the gardens well worth a visit, and we only regretted that our *cicerone* somewhat hurried us on, as is the manner with some *cicerones* who expect other visitors and other fees. There is some fine statuary in the house; but for the description of interior see Murray. I have already been carried away too far with this description of the villa gardening by the side of the lakes.

We met with much the same at Lugano, and again at Baveno, on the Lago Maggiore, where there is a beautifully-kept villa garden, and a new villa built by an Englishman; but I will not weary your readers by a repetition of the names of the shrubs and Firs, &c., which were planted there. I may mention, however, that the *Wellingtonia* was developing with great rapidity, making young quick growth, tapering far more than in any English-grown specimen I have yet seen, and the young growth of the *Pinus excelsa* and *insignis* was some-

thing wonderful. But the gem at the Villa Clara is the little chapel built in an octagon form, beautifully decorated with mosaics, frescoes, encaustic tiles, and painted windows, with a daily service. The chapel is open to all English visitors at the hotels at Baveno, and it is quite worth while to make it a Sunday resting-place. The chapel is quite perfect in its way.

From Baveno we crossed into Switzerland by the St. Gothard Pass, and I will reserve my few remarks on the vegetation, &c., we saw *en route* till another paper.—C. P. P.

## EARLY WRITERS ON ENGLISH GARDENING.

No. 7.

JOHN EVELYN.

SWITZER, the contemporary of Evelyn, and one of the best practical gardeners, and the best writer on gardening of that period, observed that "Evelyn, like another Virgil, was appointed for the retrieving the calamities of England and reanimating the spirit of his countrymen for their planting and sowing of woods; to him it is owing that gardening can speak proper English." He was born at Wotton in Surrey, the mansion of his father, on the 31st of October, 1620. He commenced his education at Lewes in Sussex, and completed it at Balliol College, Oxford. In 1640 he entered as a student of the Middle Temple, but proceeded in 1644 on the grand tour of Europe to Italy. Having exerted himself in promoting the restoration of Charles II. he was appointed a commissioner for the sick and wounded during the Dutch war. He was one of the first Fellows and of the Council of the Royal Society on its establishment in 1662. It was by his persuasion that Lord Henry Howard in 1667 presented the Arundelian marbles to the University of Oxford, for which he received its thanks and the degree of Doctor of Laws. He was also appointed one of the Commissioners for rebuilding St. Paul's Cathedral, had a place at the Board of Trade, and was one of the Council for the management of the Plantations. After the accession of James II. he became one of the Commissioners for executing the office of Lord Privy Seal, and in 1695 Treasurer of Greenwich Hospital.

Mr. Evelyn became possessed of Sayes Court in 1647 by marrying the only daughter of Sir Richard Browne, tenant under the Crown. Sir Richard, being absent as our representative in France, allowed Evelyn to reside at Sayes Court in 1651.

In the January of 1653 Evelyn writes, "I began to set out the oval garden at Sayes Court, which was before a rude orchard, and all the rest one entire field of a hundred acres, without any hedge except the hither Holly hedge joining to the bank of the Mount walk. This was the beginning of all the succeeding gardens, walks, groves, enclosures, and plantations there."

"The hithermost garden I planted about 1656, the other beyond it, 1660; the lower grove, 1662; the Holly hedge, even with the Mount hedge below, 1670."

Previously to his incurring the expense incident to all these improvements Evelyn had wisely secured to himself and heirs a long possession. The ground belonged to the Crown, and he obtained in the December of 1662 a warrant to prepare a lease to him of sixty-five acres, the portion of Sayes Court now held by him, for ninety-nine years, though the term greatly exceeds the Lord Treasurer's instruction, on rent to the Crown of £20; and 204 acres, the remaining portion, for thirty-one years at a rent of £40. In 1663 the lease was finally granted, but the rent was reduced to 22s. 6d.

In 1683 he "planted all the out-limits of the garden and long walks with Holly," and of one of them he thus speaks—"Is there under heaven a more glorious and refreshing object of the kind than an impregnable hedge of about 400 feet in length, 9 feet high, and 5 in diameter, which I can show in my now ruined garden at Sayes Court (thanks to the Czar of Moscow) at any time of the year? It mocks the rudest assaults of the weather, beasts, or hedge-breakers." This last sentence evidently refers to its being proof against the barbarian amusement of the barbarian Czar of Russia, his temporary tenant, being impelled through the Sayes Court hedges in a wheelbarrow.

In 1696 Evelyn let Sayes Court to Captain Benbow, afterwards Admiral, of whom he thus speaks in his diary:—"I have let my house to Captain Benbow, and have the mortification of seeing every day much of my former labours and expense there impairing for want of a more polite tenant." In the commencement of the year 1698 Benbow underlet the

house, together with all his furniture, to the Earl; but Evelyn soon had to regret the accommodation he had allowed to His Majesty, for in the month of May in that year we find him petitioning the Lords of the Treasury that compensation be made him for the damage the Earl had done to his house, garden, and furniture. The well-known gardener, Mr. London's report is as follows —

"May 9th, 1696.

"Some observations made upon the gardens and plantations which belong to the honourable John Evelyn, Esquire, at his house of Sayes Court, in Deptford, in the County of Kent.

"During the time the Earl of Newcastle inhabited the said house, several disorders have been committed in the gardens and plantations, which are observed to be under two heads: one is what can be repaired again, and the other what cannot be repaired.

"1. All the grass works is out of order, and broke into holes by their leaping and shewing tricks upon it.

"2. The bowling green is in the same condition.

"3. All that ground which used to be cultivated for eatable plants is all overgrown with weeds and is not manured nor cultivated, by reason the Earl would not suffer any man to work when the season offered.

"4. The wall fruits and standard fruit trees are uprooted and unnailed.

"5. The hedges nor wilderness are not cut as they ought to be.

"6. The gravel walks are all broke into holes and out of order.

"These observations were made by George London, his Majesty's Master Gardener, and he certifies that to put the gardens and plantations in as good repair as they were in before his Majesty's residence there will require the sum of fifty-five pounds, as is justified by me.

"GEORGE LONDON.

"Great damages are done to the trees and plants, which cannot be repaired, as the breaking the branches of the wall fruit trees, spoiling two or three of the finest true phillareas, breaking several hollies and other fine plants."

Lord Keeper Guildford described Sayes Court as "most boscaresque, being, as it were, an exemplar of his (Evelyn's) book of forest trees." It long since was pulled down, and its gardens built over. Several years previous to 1759 Sayes Court, mansion, and part of the grounds had been used as the workhouse for the parish of St. Nicholas, Deptford. Then it became a dépôt for emigrants, and was pulled down nearly twenty years since. There is a small drawing of the house and grounds in a map of Deptford attached to Evelyn's "Diary."

Evelyn was far in advance of his age in almost all knowledge and judgment. After the great fire of London he proposed that with the rubbish a quay should be formed from the Tower to the Temple, whereby the river there would be always full and easy of access. Not succeeding in that, he seems to have turned his thoughts towards preparing materials for re-erecting the city; for in the next year, 1667, he applied for a sole license for fourteen years, in conjunction with Gabriel Sylvius, for their invention of a kiln and furnaces for burning bricks.

Amongst the MSS. at Wotton are parts of two volumes entitled "Elysium Britannicum," and the contents are specified, but the work was never completed. If it had been completed it would have been an "Encyclopedia of Gardening" of Evelyn's time. A portion of it was finished and published as "Kalendarium Hortense." It is dedicated to Cowley the poet, his "deare and worthy friend;" and in 1690, writing to Lady Sunderland, Evelyn said, "It is now entering on the eighth edition. 'Tis now almost forty years since first I writ it, when horticulture was not much advanced in England."

Among the State Papers of the date 1664 (?) is a MS. of fifty-seven pages, being that "Kalendarium Hortense, or instructions for each month of what is required to be done in the Orchard and Ollitory Garden, and in the Parterre and Flower Garden." There is also the table and table of contents

of his "Sylva," printed in 1664; also particulars of large Oak trees found in different localities, with the prices for which they were sold; also discourses on cider by Dr. Smith and Capt. Taylor. At the end are money accounts in Spanish of the dates 1642, 1648, and 1661. One thousand copies of the first edition of the "Sylva" were sold in two years, and the author was naturally gratified by this success, so unusual in those days, as well as by being able to inform the king that the publication had caused in that same space of time "more than two millions of timber trees to be planted, besides infinite others."

Evelyn in his "Diary" states many particulars relative to twenty-six gardens he had visited in France and Italy, and fourteen in England. Among the latter is that of the Earl of Essex at Oashobury, of which he says "The gardens are very rare, and cannot be otherwise, having so skillfull an

artist to govern them as Mr. Cooke, who is, as to the mechanic part, not ignorant of mathematics, and pretends to astrology. There is an excellent collection of the choicest fruit." In its culture the gardener named was certainly a proficient. He is the Moses Cooke who, in 1679, published a favourably known book on "Raising Forest and Fruit Trees."

Evelyn gives still more special details of Lord Clarendon's mansion and gardens, Swallowfield, in Berkshire, "the delicious and rarest fruits of a garden, the skill in the flowery part, and the innumerable timber trees. There is one orchard of one thousand golden and other cider Pippins."

In 1700 Evelyn visited Beddington, "the ancient seat of the Carews now decaying with the house itself, heretofore adorn'd with ample gardens, and the first Orange trees that had been seen in England planted in the open ground, and secur'd in winter onely by a tabernacle of boards and stones removable in summer, that standing 120 yeares, large and goodly trees, and laden with fruits, were now in decay. The Pomegranades bears here."

Evelyn died at Wotton, February 27th, 1705-6, and

was interred in the family vault there after a life of unwearied utility, sincerely regretted by every man of science and every patriot.

Besides the works already mentioned, Evelyn published the following relative to the cultivation of plants: "The French Gardener," in 1658; "Terra, a Philosophical Discourse of Earth," 1675; "Pomona," 1679; "Quintiny's Treatise of Orange Trees," 1693; and "Acetaria, a Discourse of Sallets," 1699.

## NEW EARLY AND LATE STRAWBERRIES.

No. 2.

The remaining sorts I have at present to notice are decidedly late, and first of all *Excelsior* (fig. 54). This is a seedling the second generation from Cockcomb, by which I have removed the objectionable cockcomb shape altogether. The foliage is dark green, and the habit of the plant very handsome, of moderately dwarf and compact growth, much after the style of River's Elisa. The fruit is not so large as its parent, but much handsomer and of regular conical shape from which it never departs.

The woodcut represents the ordinary run of the fruit, and is far from being a large specimen. I have frequently grown

Fig. 53.—John Evelyn, Esq.

it half as large again. The quality of the fruit is excellent. Flesh white and sometimes pinky white, very solid and buttery, with a rich vinous flavour. Under glass the plant behaves remarkably well. It is, perhaps, rather bushy, and therefore requires a full-sized pot, but it bears accordingly, and I know of no forced Strawberry so good in quality or of such undeviating high flavour. Early Prolific and Duke of Edinburgh for early, and Excelair for late forcing, are not to be beaten by any sorts yet known, let anyone say what they may.

This variety has also a property to which I have before alluded. After the plants have finished fruiting the beds present a mass of bloom all over from the runners, which may be removed with a little earth, potted, and grown-on in a cool frame, or if let alone in the open ground, and should the season be mild it will ripen a second crop of fruit late in the season.

*Variegated Enchantress* (fig. 55). This is quite a novelty, at least as far as my experience goes. I never met with a variegated sort bearing a good-sized fruit.

This variety not only bears the class of fruit represented by the woodcut, but the quality is everything to be desired. Like its parent Enchantress, it produces a bright crimson-coloured fruit with very numerous small yellow seeds prominently disposed, pinky-red flesh, solid, very juicy, and possessing a remarkably rich Pine flavour. Like most variegated sorts the plant is not very large, but it bears well for its size, and is altogether a late and remarkable variety.

Next in order is *Bonny Lass* (fig. 56). The fruit of this fine late sort is very large and handsome, pale red in colour, with prominent seeds thickly disseminated, remarkably solid pinky-red flesh, juicy, and of good flavour, the flavour improving as the season advances. Plant stout and healthy, a good grower and profuse bearer. It commences ripening its fruit at mid-season, and generally lasts all sorts out except *Fragaria tardissima*. Quite the finest late Strawberry, the latest berries of which, though smaller, have frequently the highest flavour. This sort, with Early Crimson Pine and Sir John Falstaff for early and mid-season, are the three fine sorts we grow for market.

Lastly, *Fragaria tardissima* (fig. 57). This is not a sort anyone would care to grow largely, but where a little very late fruit is wanted at the middle and latter end of August, and sometimes beginning of September, this will be a desirable kind to grow. The fruit is not very large, and cannot possibly be so good in flavour at so late a period of the season; nevertheless it is sometimes very good. Colour of fruit bright red with a tinge of scarlet; seeds depressed and thinly scattered; flesh pale red, melting and juicy, with fine flavour, varying with the season. The fruit is borne in clusters on shortish footstalks, so that its blooms become quite hidden by the foliage. The plant in my soil makes too much foliage; so that to ensure success I have found it necessary to considerably reduce the quantity of foliage once and sometimes twice during the season, to enable the blossoms

in the first instance to set their fruit, and later on to ripen it. When this is done the flavour is really very good. The tendency of the plant is to set its fruit well; and from what I am about to relate I doubt not this very late sort, if it possessed no other merit than its lateness, bids fair to be one of the parents of a new race of very superior high-flavoured late sorts. These four last seedlings, together with Enchantress, Gipsy Queen, and Fair Lady form a group of late varieties, each having some peculiar quality differing from any other late sort in cultivation.

I must conclude these descriptions by observing that several years ago Mr. Laxton of Stamford was good enough to send me a seedling Strawberry which he described as a cross between the Pine and Alpine races, having then no very positive characters, and being also anything but fertile—in fact, as he said, almost a mule. He sowed the seedling Alliance and sent it to me, thinking it might possibly, if good for nothing else, become the parent of a new race. I worked away at this alliance of two original types of the Strawberry, sowing the seed of such fruits as I could get from time to time till I produced a considerable amount of fertility. Having so far overcome its mullish propensity, it struck me some two or three years ago that *Fragaria tardissima* as a very late sort, but still wanting in some respects, might make a grand second parent for a further acquaintance with Alliance; for it is a notable fact according to my experience, that you do not generally succeed in producing any very new feature by using parents on either side which in themselves already possess a

large amount of perfection. I therefore determined to cross two or three of the earliest blooms of *F. tardissima* with the pollen of Alliance, and I believe I have succeeded thoroughly; for on sowing the seed of two berries thus treated I have raised, to my mind, one of the most delicious late Strawberry-berries I ever tasted.

The season just ended is the second year of the selected plant. It bore a heavy crop of fruit which, though not at present very large, was of exactly the outline of *F. tardissima*. Some of the fruit was rather larger, but darker in colour like Alliance, dark red flesh all through, and so remarkably juicy, sugary,

vinous, and melting, that I cannot easily forget its delicious flavour, and am only longing for next season to arrive, when I hope to have the satisfaction of confirming the above impressions on witnessing the results from some twenty or more fine plants I have already reared and hope to fruit well in due course. The plant is of stout upright growth, and partakes of the character of both parents—that is, the colour of leaf from Alliance and the contour of plant from *Fragaria tardissima*, and the season will undoubtedly be late.

If these remarks should catch the eye of Mr. Laxton I shall be happy next season to return Alliance to him improved in size and fertility, accompanied (if he will accept them) by a plant or two of the new cross, to be named, if still found worthy and he will do me the honour, after Mrs. Laxton or

Fig. 54.—Excelair.

Fig. 55.—Variegated Enchantress.

Fig. 56.—Bonny Lass.

Fig. 57.—*Fragaria tardissima*.

some member of his family to be selected by himself. This little compliment, I am sure, is quite due to one who has done so much to add to our enjoyments, yearly increasing, in one of the great luxuries of our table, and for which I thank him.

I cannot close this article without alluding to the extraordinary season through which we have just passed, not only in the midland district, but generally throughout the country; the enormity of the Strawberry crop, which has been almost unparalleled; the large amount of fruit which has been totally spoiled by the incessant wet weather; and the consequent general lack of flavour in all but a few of the very best sorts. —W. ROSEN, M.A., M.D., *Morningside, Kidderminster.*

### THE WATER GARDEN.

If there is one branch of gardening more neglected than another, it would seem to be that which relates to the culture of aquatic plants, both hardy and tender. It is not possible, or even desirable, to grow the Victoria Lily in every garden; but there are smaller and scarcely less beautiful Water Lilies, which only require a tank a few feet square in which to cultivate them very successfully; and in the majority of cases the extra expense of a shallow slate tank is amply compensated by the minimum amount of attention which the smaller aquatic plants require when once planted compared with ordinary decorative plants in pots. Many of the most beautiful and interesting of all exotic water vegetation may be grown in an ordinary plant stove during the summer months, and their introduction would do much to break that everlasting monotony and sameness of material one generally finds in such structures. A slate tank, about 4 feet square and 1 foot or 14 inches in depth, is amply sufficient for one of the smaller *Nymphaeas*; and a few smaller plants, as *Pistia stratiotes* or *Limncharis Humboldtii*, only require an inch or two of space around the sides. A series of these shallow tanks might occupy one side of a plant stove during the spring and summer months, and thus, at a slight expense, afford the means of growing a very interesting collection of aquatic plants. These tanks are of a very portable size, and are readily emptied and removed in the autumn, when the plants have died down or are at rest, in which condition one tank is often sufficient to keep the tubers of such plants as *Nymphaeas*, which should never be dried off.

Most aquatics grow well in a compost of fibrous loam and manure, and they may either be planted in pots or shallow wicker baskets (which for the larger kinds are better), plunged beneath the surface.

Aquatics are now kept in stock by most of the principal nurserymen, so that they are readily obtainable. Now it is the fashion to plant out our conservatories on the natural style, it is advisable to make provision for aquatic or sub-aquatic vegetation. Even if it is a cool or unheated structure, our common white Water Lily and the American *Nymphaea odorata*, together with the fragrant and perfectly hardy *Aponogeton distachyon*, may be introduced with success; but if the water is heated by a circular coil of piping, the selection of plants may be increased by planting the lovely and free-flowering blue and rosy *Nymphaea*, *Papyrus*, and the beautiful umbrella-leaved *Nelumbium* or Sacred Bean should always find a place. Even where no regular aquatic pond or tank is provided by the architect in heated conservatories or plant houses, the *Nelumbium*, *Papyrus*, and other distinct and effective sub-aquatics, may be grown with every success by plunging tubs or barrels down through the middle in the beds or border, so as to afford the necessary means of supplying them with the requisite amount of moisture. I have seen this plan adopted in several cases, and most interesting and surprising effects may be obtained in heated houses by these or similar means.

Outdoor tanks, streams, ponds, or basins may be rendered doubly attractive by the addition of white Water Lilies, *Aponogeton*, and *Richardia aethiopica*, whilst their moist spongy margins may be judiciously planted with *Agapanthus umbellatus*, *Arundo donax*, or the hardier *Arundinarias* and *Bamboos*. Even the humblest window garden need not be less ornamental or pleasing on account of the absence of aquatics, when such a lovely plant as the Hawthorn-scented *Aponogeton* may be grown and bloomed all through the autumn and winter in an inverted bell-glass or ordinary parlour aquarium. There are many of our commonest decorative plants which double or treble their vigour when grown as aquatics, and this is especially the case with *Cyperus alternifolius*, *C. laxus*, and the white-spathed Lily of the Nile (*Richardia*). The golden-flowered

*Limncharis Humboldtii* blooms freely every summer in the open air, planted in a shallow tank in the Jardin des Plantes, and succeeds perfectly in a sunny greenhouse in this country, although generally grown in the stove. The fresh-green water Fern, *Ceratopteris thalictroides*, also grows well in a pot plunged in a pan full of water.

Apart altogether, however, from the beauty and interest of aquatic vegetation in our plant houses, the introduction of water tanks influences the climate of such structures to a wonderful extent by keeping them constantly in a state of genial humidity; indeed, the introduction of water vegetation in the manner above suggested is indirectly a saving of labour in other ways, and is certainly worth more general adoption. Between the two extremes of a gigantic and expensive aquarium for the great Victoria Lily and the modest inverted bell-glass, there are hundreds of intermediate means of growing aquatic plants which deserve the attention of all amateurs and gardeners who are not completely led on by habit or fashion in this as in many other matters relating to the embellishment of our gardens.

The following list of aquatic plants may be useful to some in making selections:—*Nymphaea pygmaea*, white; *N. oerulesa*, blue; *N. alba*, white; *N. odorata*, white; *N. roses*, bright rose; *N. rubra*, rosy crimson; *Pistia stratiotes* or Water Lettuce, bright green tufted foliage; *Vallisneria spiralis*, bright green leaves and curious spiral flowering stems; *Nelumbium speciosum* or Sacred Bean of the East, bright rosy flowers and large peltate foliage, borne on long stalks, which give them the appearance of so many umbrellas; *Cyperus alternifolius*, Umbrella Sedge of Madagascar; *Ceratopteris thalictroides*, aquatic or water Fern, *Limncharis Humboldtii*, yellow; *Thalia dealbata*, fine glaucous foliage; *Aponogeton distachyon*, white; and *Richardia aethiopica*, white Trumpet Lily, perfectly hardy if plunged 1 foot or 10 inches below the surface, so as to guard against frost.—F. W. B. (in *The Gardener*).

### SNOWFLAKE AND EUREKA POTATOES.

HAVING seen several accounts of the crops raised from single pounds of seed of the above-mentioned varieties of American Potatoes, I venture to forward an account of the produce grown here from the same quantity of seed. As I am a competitor for the prizes offered by Messrs. Hooper & Co., the Potatoes for planting were weighed, the sets counted and planted, and the produce weighed in the presence of their agent besides a number of other witnesses. They were planted on the 13th of April, and Snowflake was lifted on the 13th of August, the produce being 638 lbs. Eureka was lifted a week later, and the astonishing quantity of 1082½ was the produce of 1 lb. of seed. Snowflake is a remarkably handsome Potato, but with me has suffered severely from the disease. Eureka is a later and more robust variety than the preceding, and produces very large Potatoes, three hundred tubers weighing 369½ lbs. It appears to suffer less than Snowflake from the disease.—F. FORD, *The Gardens, Capeethorne.*

### COVENT GARDEN.

THE neighbourhood of Covent Garden abounds with objects of historic and architectural interest. Now dedicated to the goddesses Flora and Pomona, its market held in high repute, its stalls crowded, and its surrounding streets bustling with the traffic of the great city, it was once the garden of a convent, afterwards a fashionable part of town, the residence of persons of rank, opulence, and literary fame. In the days of the early Georges it was the resort of men whose names crowd the canvases of the most brilliant picture of the time. Looking back well and that before the suppression of the religious houses this spot was a garden or burial-ground: hence the name "Convent" or "Covent" Garden; it then devolved to the Crown, and the property was first given to Edward Seymour, Duke of Somerset. At his attainder it reverted to the Crown, and was granted to John Earl of Bedford in 1552. The area of Covent Garden, devoted to the sale of fruit and vegetables, has since 1680, the year when it was first laid out as a square by Inigo Jones for Francis the fourth Earl of Bedford, experienced many vicissitudes. What the original design of Inigo Jones was for the square or "market-place" may be gathered from the few vestiges we have of it, though Mr. P. Cunningham seems to think the square was never completed, if fully designed. The Piazza, as designed by Jones, is said to have been suggested by the square at Leghorn; the colonnade was

first called the "Portico Walk," an appropriate name enough. The term then changed to "Piazza"—an Italian word for square or place—subsequently misapplied to the arcade, being out of place. Hollar's view of Covent Garden in 1647, looking in the direction of the church from Russell Street, shows the south-eastern part of the colonnade destroyed by fire, and in the distance the picturesque gabled fronts of Hen-i-etta and King Streets. Another picture, by Inigo Jones himself, at Wilton House, Salisbury, the residence of the Earl of Pembroke, shows the garden in its original state, with the tree in the middle; while Hogarth, in his "Morning," has immortalized on canvas King's Coffee House, under the portico of the Church of St. Paul's. The Square and Piazza figure also in the drama of the Stuarts. Gay, too, has given us in a few lines of his "Trivia," a vivid picture of the church as it existed in his day:—

"Where Covent Garden's famous temple stands,  
That boasts the work of Jones' immortal hands,  
Columns with plain magnificence appear,  
And graceful porches lead along the square."

The "famous temple" here spoken of is the present Church of St. Paul, whose columns and projecting cornice are noted for their Vitruvian proportions. The original structure was erected between 1631 and 1638, and forms the west side of the "Garden." The "graceful porches" are in allusion to the porticoes which ran along the north and eastern sides of the square, and which, for aught we know, were intended to have surrounded the area, and to have invested it with an air of truly Italian magnificence. Unhappily Jones's design was never completed, and if it had been it is probable the present square would have been a more attractive place. The present market was established by charter in 1671 granted to the Earl of Bedford. At that time a mere handful of salesmen tenanted the stalls and sheds, which were of the most temporary kind. Strype, one of the few topographical chroniclers of old London we can rely upon, speaks of it as it was in 1689, and Pepys in his "Diary" alludes to the locality:—"The south side of Covent Garden square lieth open to the Bedford garden, where there is a small grotto of trees, most pleasant in the summer season, and on this side there is kept a market for fruit, herbs, roots, and flowers every Tuesday, Thursday, and Saturday, which is grown to a considerable account, and well served with choice goods, which make it much resorted unto." The ancient boundary of the parish of Covent Garden was the subject of considerable contention some years ago, and a committee was appointed to investigate the limits. An ancient map from a survey made in 1686, and given in Strype's edition of Stowe's "Survey of London," clears up the matter, and helps us to form an opinion of the true extent of the parish, which was made a distinct parish by an Act of Parliament 12 Car. II., 1660. Stowe minutely particularises the inward boundaries of the parish and Bedford House, which is said to be "seated in the Strand, but runneth backwards, being a large but old-built house, having a large yard before it for the reception of coaches, with a spacious garden, having a terrace walk adjoining to the brick wall next the garden, and from thence received the prospect thereof." Bedford House was pulled down in 1704, and the result of the committee's investigations, and evidence adduced, shows that the parish establishes the claim to the site of Bedford House, though, by some irregularity, certain assessments to the land-tax were discontinued, and an injustice done to the ratepayers. Bedford House and out-buildings, from the plan we have alluded to, had one front towards the Strand, and occupied the sites of Southampton and Exeter Streets, the parish boundary circumscribing this property. Afterwards, early in the eighteenth century, great progress was made, though no permanent buildings marked the site of the present market; and contemporary prints show the square enclosed by a post fence, and having a column of the Corinthian order in the centre, which was taken away in 1790. During the time of the first Georges the vicinity was patronised by the fashion and learning of the day. Dryden, Pope, Johnson, Butler, Addison, Voltaire, Garrick, Sir James Thornhill, Hogarth, and Dance resorted to the neighbourhood, whose coffee houses and cellars became noted, and whose piazza was thronged by fashionable loungers. Sir Godfrey Kneller, state painter, lived near Covent Garden Theatre; Wilson, the painter, lived in the piazza; and Sheridan frequented the Piazza Hotel.

But the Covent Garden of the present day has a somewhat altered aspect. We content ourselves with noting some of the changes that have taken place during the last few years in

the locality. Its square is no longer crowded in the daytime by the fashionable, nor is it at nightfall the resort of footpads and Mohocks, as it was in the reign of George II. Shenstone and Gay have given a picture of life at that time; Shadwell's comedy of the "Scourers" shows the danger of the London streets at night early in the eighteenth century; and Mr. Cunningham alludes to the pranks played upon the watchmen of the time. All this has changed, and if we have other inconveniences to submit to, such as the overcrowded and uncleanly state of the streets round Covent Garden on market days, we are at least safe in our rambles, and our absolutely sanitary wants are tolerably looked after. To begin with the Garden, whose aspect our readers are all doubtless acquainted with. The market has lately undergone some improvements. The original structure, built from the design of the late Mr. Wm. Fowler in 1830, for the sixth Duke of Bedford, is more conspicuous for its granite colonnade of Tuscan columns which front the shops than for any striking elegance of structure. Indeed, few strangers would imagine from the precincts of this market that Flora was enthroned here, or that Nature here emptied her lap of produce. Considering it the central congress of the vegetable world, in which every variety of plant and vegetable, from the humble esculent to the choicest of flowers, may be seen, it can hardly be said to be a fitting receptacle since the erection of larger and more costly markets, and we hope the Duke of Bedford will some day expend some of the fortune accruing to him from this fine property upon its improvements. Lately, we are glad to see, a light iron and glass roof has been erected over a portion of the market, and we might suggest some improvement to the main arcade in the shape of glass panels, and a little decoration in the timber roof and clerestory, if the old structure is to remain. The centre arcade is very much too narrow for the present traffic, however well it may have answered its purpose forty years ago. No doubt an iron and glass structure, somewhat after the design of the Floral Hall, by Mr. Edward M. Barry, close by, would be more in unison with its purpose than the present basilican-looking building, with its flat kingpost, close-boarded roof, and its Tuscan clerestory. A well-proportioned centre vista of greater width and height than the present, and the transverse vista only developed, would meet the demand of the trade, though a slight encroachment would be made upon the side rows of shops. As it is, the new roof somewhat dwarfs the present centre building, though it provides shelter for a large area devoted to the sale of fruit and vegetables. The construction adopted, though exceedingly plain, is light and effective. The roof comprises the area between the centre arcade and southern row of shops. The ribs are semicircular, supported on round cast-iron columns resting on high bases, and are of plate iron with double flange, a light spandrel supporting the straight rafters. Running along the top of the roof is a raised ventilating skylight with glass roof, supported by smaller semicircular ribs springing from the larger ones with light spandrels, and having a wide overhanging roof. The side upright lights are composed of a series of semicircular-headed openings. The part of the main roof above the side shops forms a clerestory above the roofs, and consists of an arcade of light iron with a frieze panel of circles over the lights. Below this clerestory the pillars are cross-braced longitudinally by circular ribs with circle spandrels, each arch embracing the width of one shop. The ribs of the roof have round iron cross bracing to stiffen them lengthwise, above which the upper half of the main roof is glazed; below it is boarded. The glass is rough plate, fitted into light sash bars of T section. The iron ribs are coloured a light blue of two shades, and the pillars and bases are of buff and chocolate. The works have been carried out by Messrs. Cubitt. On the south-east corner, with its entrance in Wellington Street, the recent addition in the shape of a flower market is certainly wanting in character or expression, and its heavy front in no way suggests its purpose.

Confining ourselves to the square, we may notice that new buildings have scarcely replaced the old haunts. The "Bedford" still retains at least the external appearance it had when Garrick, Foote, Sheridan, critics, scholars, and wits frequented its coffee room. The late Mr. Timbs has popularised this once famous house in his "Curiosities of London." Its stone arcade, now painted, looks modern; but traces of its age are apparent on examination. On close inspection of the arcade near Evans's we found the groined arches have thrust out of perpendicular the rather slight piers which support the front of the hotel, and we should suggest that an iron tie rod or two be inserted. Probably the defect is not of recent origin. It extends through

the arcade, but it gives an insecure appearance. Close to this and at the end of the Piazza, is Evans's famous hotel and supper rooms, once a mansion dating from the time of Charles II., though afterwards rebuilt. Its fine carved staircase, painted ceiling, and new music hall—the design of the latter by Mr. Finch Hill—are features of interest, and are memorials of a past full of associations.

The Church of St. Paul on the west side of the market was, as is recorded over the eastern doorway, totally destroyed by fire in 1795, and was rebuilt upon the old plan of Inigo Jones by John Hardwick, the architect. Its architecture, familiar to the student of London antiquities, was much lampooned by that noted art-critic, Horace Walpole, for its barn-like overhanging roofs, and its Tuscan proportions. It is rumoured the Duke of Bedford intends to restore the church, and re-instate its old services. The author of "Hudibras" lies in the graveyard, and we believe a flat, almost undecipherable stone marks the spot near the east end of the north wall, though there is a conflict of opinion on this point. Other celebrities repose here also—among them Sir Peter Lely, the painter; Estcourt, Edward Kynaston, Wycherley, and Macklin, actors and dramatists; Worsdale, the painter; and John Wolcot, the satirist. We understand, on good authority, the tablet of Charles Macklin, the comedian, was taken down by the last restor. One of the latest and probably best adaptations of iron to architectural purposes is the Floral Hall at the north-east corner of the square, and which runs parallel and close to the new Opera House, with a covered entrance in Bow Street. This building seems to unite the floral and festive elements of the neighbourhood. We think its architect, Mr. Edward M. Barry, the architect also of the adjoining Opera House, successfully blended the Italian facade of his great building with this work. The project of forming a central flower market is due to Mr. Gye. On the rebuilding of Covent Garden Theatre, after its destruction by fire in 1856, the idea was realised by the present iron and glass arcade. Though designed as a flower market, such is the "irony of fate" that it has chiefly been used as a concert hall, and is now proposed to be turned into a skating rink. The size of this structure is belied by its contiguity to the Opera House, which completely dwarfs the proportions. Few who pass it believe it to be a structure divided into a nave and aisles 280 feet in extreme length, and having a frontage of 75 feet in Bow Street. The nave or central arcade is 50 feet span, and the aisles are each 12 feet 6 inches. The dome at the crossing of the roofs at the Covent Garden end is a conspicuous feature. The height of the circular ribbed iron and glass roof is also 50 feet to the crown, and to the lantern-roof ridge 70 feet. The ribs are 21 feet 6 inches from centre to centre, connected by light purlins, and are supported by twenty-four hollow columns from the basement on York stone slabs, 2 feet 6 inches square and 2 feet 8 inches thick, resting a solid bed of concrete 2 feet in thickness. At the springing of the arches in the hall enriched capitals adorn the columns, which are cast iron hollow, and the capitals perforated to ventilate the basement. The side avenues have lean-to roofs, and are connected to the main roof by ornamental spandrels. The hall floor consists of thirty-two arched girders, 18 inches deep, with two hundred others placed transversely, having flanges to receive hollow tile arches. The roofs are covered with bent Hartley & Co.'s glass, 21-in. to the foot. In the facades of this structure we have the circle as the leading element in the design. This figure is the predominating one in the circular-headed radiating panelled gable; it adorns the faces of the pilasters and spandrels, and, in fact, is visible everywhere. We may add Mr. Henry Grissell, of the Regent's Canal Ironworks, was the contractor. We admire the recessed panelled fronts within the projecting wide runs of open ironwork, which take off the usual fatness of iron buildings in a manner to be commended, and we have before hinted the value of this kind of effect in iron buildings. Let us wander through the neighbourhood so loved by Dickens and by Thackeray. Every street recalls the memories of literati, artists, dramatists, and notabilities of wealth or fashion. King Street and Henrietta Street can boast of Coleridge the poet and other residents of note. One of the old houses we visited in King Street retains sumptuous interior fittings—as mahogany doors and dados, handsome cornices, and massive mouldings. Garriek Street within the past few years opened up a thoroughfare to Leicester Square. Tavistock Street, partly on the site of the gardens of old Bedford House, according to a rare map from a survey of W. Lyborn, in 1686, was once the Regent Street of fashion; in it Defoe, the author of "Robinson

Crusoe," lived. Maiden Lane was noted for its "Older Cellars," a resort of "swells." Turner lived in the street now occupied by the extensive show rooms of Messrs. Cox & Sons, the decorators, and the well-designed Roman Catholic Church of the "Sacred Heart," opened by Archbishop Manning last year. Chandos Street is noted as having seen the first introduction of the "balcony," that English feature of our houses, which was first set up here, and was said to be the invention of Lord Arundel. Messrs. Benham & Froud have a warehouse in this street in progress of completion, from a design of Mr. Frederick Meeson of Adam Street, to which we shall refer further on. Southampton Street is associated with Garriek. James Street borrows its name from the Stuarts, and many other streets from the Russell family—all are deeply interesting, both on account of the pictures of old London life they open to our view, and the various architectural changes which they have undergone.—(*Building News*.)

### PRINCE OF APPLE-GROWERS.

It may not be known that we have in America an "Apple prince," whose income from his handsome Apple orchard on the banks of the Hudson river exceeds that of many bankers. He is a scion of British nobility and the chief among American farmers—that is, his lands are made to produce a better return to capital than in any other instance on record. Robert L. Pell, the gentleman to whom reference is now made, is the lineal descendant of Lord Pell, a peer of the realm, who obtained a patent for a vast tract of land in Ulster county, near the old town of Esopus. Mr. Pell occupies the ancestral farm, which contains 1200 acres, all of which he cultivates under his own personal attention. During the spring, summer, and the autumn he resides upon the place.

Mr. Pell's father, who was noted for his good judgment in agricultural matters, stopping many years in the little village of Newtown, L. I., observed two Pippin trees of English origin, whose fruit was much sought for. The one produced an Apple tinted with yellow and red, and the other of a green hue, the difference in colour being solely caused by the difference in the soil. He was so much pleased with the fruit that he determined to create an extensive orchard of a similar kind. The cuttings were obtained from time to time, trees were planted and grafted, and after many years of perseverance and labour the grand orchard was in existence. Mr. Pell then could show 200 acres planted with the Newtown Pippin alone, and containing 21,000 trees. He then remarked, if each tree should yield his son one dollar a-year it would be a handsome income. His plan, however, has been greatly exceeded, for some of these very trees have yielded eighteen bushels at a picking.

During Apple harvest about one hundred men are employed, and the work generally requires a fortnight. The rule is to pick the trees clean, and not to let go of an Apple until it rests in the basket. The latter are laid carefully on the ground, and the teamster picks them up with equal care, and conveys them to the Apple house. The latter is one of Mr. Pell's inventions, and he has four in use. They are spacious structures, perhaps 40 by 100 feet (such, at least, is my recollection from seeing one of them), and are what may be called two storeys high. The first storey has no windows. You enter by a wide door, and the Apples are seen covering the entire interior to the depth of 4 feet. The upper part of the building has a few windows, and the door is grated, so that when closed there is an ascending draught. The fruit will while in this place discharge a very large amount of moisture, and thus deliver itself from the chief cause of decay.

An Apple house at such a time is really a fine sight. In three days the sweating is done, and the draught removes the moisture. The fruit is then sorted, and all below a certain size are carted to the cider mill, while the rest are packed for shipment. They are placed in boxes, each of which contains one hundred of the best Newtown Pippins, and are at once shipped to Liverpool. Mr. Pell's fruit is well known there, and he has adopted the custom which prevails in the Orange and Lemon trade in this city—viz., selling it by auction. The sales are largely attended, and the Pippins from the Pelham farm are sold all over Europe. They sometimes bring 14s. a-piece by the box. Such is the value of a reputation, and in this point the Pelham fruit has for forty years been unrivalled.

Mr. Pell has 80 acres devoted to Grapes, which are in great demand. He has a peculiar way of placing the best (if there

be any difference) at the bottom of the basket; and hence his brand needs no recommendation. He has 800 acres under general cultivation, and with the assistance of improved machinery the work is done by nine regular hands, with an extra force during fruit-picking.—(*Boston Cultivator*.)

#### NOTES ON VILLA AND SUBURBAN GARDENING.

**KEEPING FRUIT.**—The fact that storing places for fruit are mostly of a very inconvenient and also unsuitable character, generally suggests to one that the greatest care is needed in gathering not to injure it in any way, and to take care that none but sound fruit be put away. Now, as there are various ways of keeping fruit, several of which I have tried through necessity, it will be as well to state how I have found it here answer. I allude only to Pears and Apples. Having at one time no fruit room, my first experiment was with storing them in vegetable and other hampers as well as boxes. A quantity of moss was procured and well dried, and afterwards beaten in order to free it from rubbish; it became thus very light and soft. The fruit after being gathered was laid out thinly for a few days, as most kinds of fruit will sweat a little. The bottom of the hamper was lined with the moss and a layer of Apples placed upon it; a layer of moss over these, which must be a very thin one—just sufficient to prevent the Apples touching each other; then another layer of Apples: in this way till the hamper was filled. There is a little air passing through them in such baskets, but for boxes I made several holes in order to have the air admitted. After being filled they were stood in a dry yet cool room, with the bottom clear from the floor.

It is most proper for only one sort to be packed in each basket, as the time of coming to maturity differs with the different kinds. They were protected from frost, and I must say they kept well. The stock not being very large they were all used by the early days of February, and were packed in October. There were six sorts, and of these the Winter Queening, Northern Greening, and Alfriston kept best. The following year, having more of them, a dark room was secured for them, in which many were laid in a heap, and others spread on the floor with clean wheat straw under and over them; others were put into small casks with clean oat chaff amongst them. This is valuable to keep them in when it can be obtained, it being very light, clean, and soft as silk, and in which the fruit kept uncommonly well. Others were packed into earthen vessels and covered with bran for an experiment, but the bran in time became musty, and the fruit had to be taken out of it. This room was at the top of the gardener's house, and was a dry yet cool room. The fruit, which laid in a heap, as might be expected did not keep so well.

One great object should be to keep the fruit in an even temperature, not, of course, hot and dry, but cool and dry; this will prevent the fruit from shrivelling. The fruit should be looked over twice, and if any signs of decay appear remove them. Generally speaking the dessert Apples, such as the Ribston Pippin and Pears of the larger kinds, are each wrapped in soft paper before packing away, and as a rule the late kinds of both Apples and Pears were unpacked a few days before wanted; and the Pears, especially if not ripe, were exposed to a higher temperature and full light to finish their ripeness. There is not a doubt that such a way of keeping fruit involves more trouble; but then where there is no regular fruit room, or if there is, and is not commodious enough to lay the fruit out thinly at first, the next best method is the one to choose.

In my present fruit room I lay the fruit on a layer of moss. I have used straw or hay; but the first is too hard, and with weighty fruit it bruises it, while hay soon becomes musty and imparts to the fruit an unpleasant flavour.—T. Biscoe.

#### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

##### KITCHEN GARDEN.

We have not had any heavy rains since the end of July or very early in August, so that *Celery* has required good soakings of water. The earliest has been earthed-up a week or two ago, and is now ready for use; later crops will not be earthed-up while there is no danger of the plants being injured by frosts. We have had much of the best *Celery* spoiled through decay about midwinter and onwards, and have fancied that this was owing to its being earthed-up too early, and, perhaps, the mould might have been allowed to fall into the hearts of the plants. In earthing-up *Celery* care must be taken to keep the leaves together, and in an erect position; a good way is to tie the whole with a strip of matting, not too tightly, but only sufficient to keep them together. The mould ought also to be broken up finely, and should be dry. *Cardoons* are not much grown, but those who cultivate them will now be preparing to earth them up, so that they may come into use about the middle of October and onwards. A good way is to place some clean straw out to the required length in an upright position against the plants, and

then tie the leaves in with the straw, placing the mould against the plants with the same care as is required for the *Celery*.

Our work has been hoeing between the rows of growing crops, and digging vacant ground. Even the quarters that will be trenched have been dug over, for we disapprove of trenching a hard surface and throwing the earth in lumps down to the bottom of the trench. When the ground intended to be trenched has been dug over first, and exposed for a few weeks, the surface spit is then in the best condition to be turned into the bottom of the trench. Coleworts, Spinach, Broccoli, and all winter crops, even if there are no weeds amongst them, should be Dutch-hoed. Onions and Lettuce have been sown, the varieties being White Spanish and Brown Globe. The Lettuce seed was mixed with that of the Onions and sown with it in the rows. Of course, as soon as the Lettuce plants are strong enough they are planted out into the borders, where they usually stand well through the winter.

**MUSHROOMS.**—It is now time to prepare the material for the beds. The staple of this is horse droppings collected from the stables. The little straw that may be mixed with it will be of some benefit to the bed and should not be removed. The manure should be thrown into a heap or ridge according to the quantity. If large beds are to be made up the manure must be in ridges; it ought to be protected from rains, and must be turned over every second day, being careful to turn the outer part of the heap into the centre. When the rank steam has been thrown off the manure may be spread out to dry if it is too wet, and when it is spread out it ought to be turned over every day. The manure ought not to be wet when it is used for the bed. Many different methods have been recommended to make up Mushroom beds. Some make up the dung in ridges in the form of a triangle and spawn both sides, others have beds sunk into the ground; but the usual and best way is to make up the beds on stages erected round the house, on tiers one over the other. A 9-inch board is fastened to the front to sustain the bed in its place, and to prevent its component parts from falling off. The manure must be beaten down firmly, and when the heat has sufficiently declined the spawn is inserted, and an inch or so of fine loam is placed over the surface of the bed. Should the heat decline too much some dry hay or straw must be laid on the bed, and it is astonishing the effect this has either in promoting or sustaining heat. We fancy that much of success or failure in cultivating Mushrooms depends not so much on the heat of the bed as upon the amount of moisture contained in it; but we would rather err on the side of dryness, as the spawn will run in a dry bed, whereas an overmoist state of the manure will kill the spawn, and if it is ascertained that the bed is too dry water can be applied to it.

##### ORCHARD HOUSE.

It is now a busy time amongst the pot trees, as the largest proportion of them require repotting, and it is best to have this done as soon as possible after the 1st of September, so that the trees may become established before the leaves fall; if they do not, the probability is that some of the shy-setting sorts will not have a crop of fruit next season. It has been stated before that in potting it is sometimes necessary to reduce the ball of roots to a considerable extent, so that the tree may go into the same-sized pot that it had been in previously. In doing this a large proportion of the best roots are removed, but the house is kept close for a few days, and the leaves are frequently moistened with the syringe. Under this treatment fresh rootlets are produced in three days, and the check which the trees experience is beneficial rather than otherwise. Good clayey loam is essential to the successful culture of fruit trees in pots, and it should be used in the proportion of four parts to one of rotted stable manure.

The principal element of success in orchard-house culture is liberal supplies of water at the roots, and when large quantities of water are required the drainage should be perfect. We place the crooks carefully in the bottom of the pots, and over them some fibry loam from which the clay particles have been shaken. This prevents the finer portion of the compost from mixing with the drainage. In potting, the loam must be pressed in quite firmly with a wooden rammer, and finishing off at the top with some of the finer particles.

Nearly all the fruit has been gathered except *Desse Tardive* Peach and the very late sorts, such as *Lord* and *Lady Palmerston*, *Salway*, &c. These are very useful for furnishing dishes when the other sorts are over. *Desse Tardive* is the most certain in bearing, and it is an excellent sort. Plums are over except *Coe's Golden Drop*. We shall be glad of the fruit, as the flies do not attack it in the house, whereas out of doors they are attacked before they are ripe. Not being very successful with Pears either on the walls or planted out, it is satisfactory to be able to gather first-class fruit of the best sorts from the pot trees. *Doyenné du Comice* and *Chauumontal* are specially fine; nor have we ever before seen such good examples of *Beurré Hardy* and *Souvenir du Congrès*.

##### PLANT STOVE AND ORCHID HOUSES.

The plants were removed into the house early in the month.

after it had been painted, and we were rather afraid that the sun, which acted powerfully on the glass, would injure some of the plants, but none of them have suffered in the least. We admit air rather more freely at this season, and the plants are exposed to as much sunshine as they will bear. There is not so much moisture in the atmosphere from evaporation from now until March next year. We have been repotting some plants from pots which it is not desirable they should remain in through the winter, and young plants that have been struck from cuttings recently have been potted off. Amongst them are *Dipladenia Brearleyana*. Nearly all this class of plants have striking characteristics about them. Many are extremely beautiful, but this garden variety is the most magnificent that has yet been obtained. It strikes very freely from cuttings, but the young plants require careful handling during the operation of potting them off. The newly-potted plants must also be quickly returned to the place from whence they were taken, so that they receive no check to their growth. If the pots can be plunged a little, say to half their depth, in a bottom heat of 85° or 90°, they will start more quickly into growth. The potting material used is equal parts of turfy loam and turfy peat, with a liberal proportion of silver sand.

*Stephanotis floribunda* has also been potted-off from the cutting pots; the treatment and soil is the same. *Ixoras* are potted in peat entirely. We have also potted Ferns, *Adiantums*, and *Davallias*. Of the latter species *D. Mooreana* is the very best, if it is not the finest, Fern in cultivation, and being of rapid growth it soon forms a large specimen. Like all the *Davallias* the roots do not penetrate deeply into the ground, and if the ordinary pots are used they ought to be filled nearly half full of drainage, nor should the plants be potted deeply into the pot; the rhizomes should not be covered with the mould. Loam and peat in equal proportions is good potting material for it.

It has also been necessary to repot some of the *Orchids*. Small recently-imported plants that had been potted on their arrival into the smallest pots it was possible to cram the roots have made growths, and are now making plenty of healthy roots. This is always the most suitable time to repot. At this season especially a very small shift is better than placing too much material about the roots. Thus, plants in 8-inch pots should be repotted in 4½-inch, and other sizes in proportion. Thrips are the only insect pests that give us much trouble at this time; the difficulty is to reach them without injuring the plants. When *Orchids* are attacked we can only persistently wash them off by hand with soapy water. We have sometimes fumigated with tobacco smoke, but it is very dangerous work, as valuable plants have been much injured by the smoke.—J. DOUGLAS.

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

CRYSTAL PALACE COMPANY (Bees and their appliances).—September 21st to 23rd.—Sec., J. Hunter.  
LONG SUTTON.—September 22nd and 23rd. Mr. J. W. Swain, Sec.  
ROYAL HORTICULTURAL SOCIETY OF ABERDEEN.—September 23rd. Mr. A. J. Rennie, 128½, Union Street, Aberdeen, Sec.  
ALEXANDRA PALACE (Potatoes).—September 29th and 30th. Mr. P. McKinnlay, 23, Upper Thames Street, London, Hon. Sec.  
JERSEY.—Autumn October 18th, *Chrysanthemums* November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

## TRADE CATALOGUES RECEIVED.

Thomas Bunyard & Sons, Maidstone.—*Select List of Dutch Bulbs, &c.*  
G. Yates, Underbank and Royal Oak Mills, Stockport.—*Catalogue of Bulbs, Strawberries, &c.*  
Barr & Sugden, 13, King Street, Covent Garden, London.—*Descriptive Catalogue of Bulbs and Plants.*

## TO CORRESPONDENTS.

NOTICE.—Our pomological helpmate being absent we shall be unable to name fruits for three weeks to come.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

PLANTING HALF-STANDARD ROSES (C. C.).—Three feet will be a distance sufficient between Rose trees on stakes 2 feet high.

BOOKS ON GARDENING (C. S.).—The "Garden Manual," 1s. 8d., and Keane's "Indoor Gardening," and "Outdoor Gardening," each volume 1s. 8d., all free by post from our office at the prices quoted, would suit you.

PRESERVING FILBERTS AND COB NUTS (S. J. Cox).—We remove all the husks and place them in jars and boxes in alternate layers with damp sand. The jars and boxes are kept in a cold cellar. If you wish the husks to remain on, and the nuts for winter use only, have the sand quite dry.

INTRODUCTION OF THE POTATO (K. E.).—There is a portrait of Gerardes with a flowered sprig of the Potato in his hand appended to the catalogue of the plants growing in his Holborn garden. This was published in 1595. He states that he received the Potato from Virginia. We know of no earlier mention of its being in England.

FERN DISQUALIFIED (F. Petek).—The Judges were right; the specimen sent to us is not a native Fern, but is *Adiantum cuneatum* from Brazil.

SALINE MANURES (An Old Subscriber).—Each of our answers is correct. The last answer you refer to related to different salts.

TRANSPLANTING HARDY FERNS (Oliver P.).—The early part of October would be a good time to move hardy Ferns, taking them up with good roots and soil adhering, and giving a good watering, or you may defer the removal until early in March. Fern "seed" (spores), may be sown now, or so soon as the spores are ripe. They require to be scattered over a surface which is kept constantly moist, and they germinate sooner, and more quickly attain size by being covered with a hand or bell-glass. Ferns do not grow well in sandy soil unless of a vegetable or peaty nature, both of which retain moisture. To a soil of very sandy loam add a part peat and a part of rather strong yellow loam, leaf soil being useful.

CAMELLIA CASTING ITS BUDS (J. R.).—It may be due to a sudden check by the want of water (for once only being sufficient), but a more likely cause in your case is the exposure of the plant to the full sun, and a defective root action. Add some loam to your peat, at least half good turfy loam, and repot at once. Particulars of treatment you will find in the "Greenhouse Manual."

STANDARD OF MERIT IN CUCUMBERS (Idem).—In the "Cottage Gardeners' Dictionary" it is given as follows:—"Length not less than 18 inches; diameter, one-ninth of the length; colour, dark green; spines, black and numerous; bloom unremoved; circumference, circular and equal throughout; neck and nose, each not more than a diameter long; flesh, crisp and juicy; flower, remaining on the fruit."

WINTERING COLEUS (Idem).—For soil use three parts turfy loam and one part leaf soil. For wintering safely the temperature should be 45° to 50° from fire heat, watering only to keep fresh.

FRUIT TREES FOR EAST WALL (Salop).—The extent of wall you do not give, nor the number of trees required. *Pears*.—\*Jargonelle, Beurré d'Amanlis, \*Beurré Superfin, Gratiol of Jersey, \*Urbaniste, Doyenné du Comice, \*Marie Louise, \*Beurré Diel, \*Beurré Bechellier, \*Gloire d'Orléans, Knight's Monarch, Winter Nellis, \*Josephine de Malines, and Ne Plus Meuris. *Plums*, *Dessert*.—\*Judy Green Gage, \*Golden Gage, \*Kirke's, Jefferson, \*Green Gage, \*Transparent Gage, and \*Ooe's Golden Drop. *Kitchen Plums*.—\*Early Prolific, \*Prince Englebert, \*Victoria, \*Pond's Seedling, \*White Magnum Bonum, Belle d'Orléans, \*Empress Eugénie, Frogmore Early Bigarreau, \*May Duke, and Late Duke. Those marked with an asterisk will suit if too many are named.

LIQUID MANURE FOR ROSES (H. C.).—Guano 1 lb. to a gallon of water is suitable, but neither it nor any kind of liquid manure ought to be distributed over the foliage of the plants, but upon the soil about them, and given in this way it will be beneficial.

CRINUM AMABILE.—PROPAGATING CENTAUREA CANDIDISSIMA (W. Bolton).—*Crinum amabile* requires to be kept during winter rather dry in a stove temperature, and would not, we fear, succeed in a house from which "frost were only kept out." *Centaura candidissima* is best struck in early spring in mild bottom heat, though it will strike in autumn in gentle top and bottom heat; the only thing to guard against is damping-off.

PIPING REQUIRED FOR CUCUMBER PIT (J. S. W.).—From the pit 86 feet long and 6 feet wide you will require two rows of 4-inch pipes the length of the house for top heat, which should be in front, or at least one of them, and the other in the pathway, not nearer the glass than 15 to 18 inches. It will have a pathway at the back of the pit, and this being 2 feet wide you will have a bed about 4 feet, and this will require two rows of 4-inch pipes. The pipes should be 18 inches from the top of the pit, and the top of the pit in front 18 inches from the glass. Altogether you will require about 160 feet of 4-inch piping.

STRAWBERRY PLANTS IN POTS (A New Subscriber).—The plants you have now in 8-inch pots will, unless strong and well rooted, be of but little value for fruiting in pots, as they ought now to be well established in the fruiting pots. If you wish to try them shift at once into 6-inch pots, and drain the pots efficiently, pot very firmly, using a compost of rich, turfy, strong loam, and after potting place them outdoors in an open yet sheltered position, placing them on ashes or other hard bottom, keeping well supplied with water, and removing all runners as they appear. They would succeed at the back of the house, but ought to be only half the distance you name from the glass.

CUTTING-IN CUPRESSUS LAWSONIANA (J. W., Aberdeen).—This very handsome Cypress stands cutting-in well, and makes a splendid screen, but it does not break well from the old wood, so that in cutting-back you will need to leave some green spray, and as evenly disposed as possible. When cutting-in is intended it should be commenced early, so as to prevent the plants becoming bare of spray or growing parts near the stem. We should cut-in moderately at first, and by removing the strong growths you will induce the spray nearer home to become more dense, and by annually doing so the size may in a few years be considerably reduced without interfering with the symmetry of the plants. The end of March or early in April is the best time to shorten the growths, or you may remove any irregularities now.

TIMES FOR OPERATIONS (H. E.).—The times recommended for performing operations, whether published in this Journal or the "Garden Manual," may be safely followed in any part of the British Islands. If we modified the times in any locality it should be in the far north, where we might sow a little later in the spring and a little earlier in the autumn.

ROSE LEAVES MILDWEED AND RUSTED (Miss E. H.).—Dust them thoroughly with flowers of sulphur, and keep the roots well watered and mulched. The *Ancuba* leaves excessively white are not uncommon.

**STORING PEARS AND APPLES (F. J.).**—Having no fruit-room you will be under the necessity of storing them in your coolest room, and if not dried by a fire in close proximity so as to make the air very dry, it will enable you to keep the fruit without shrivelling. It should be dark, and the fruit not exposed to strong light until ripening is commenced. The cooler the room the better if frost is excluded. Pears and Apples may be kept somewhat later than their usual period by placing them in pure dry silver sand in earthenware jars, placing them in a cold place; but this is chiefly applicable to late and not to autumn or late summer kinds. It is useless to expect "Williams's Bon Chrétien" ripe this month to keep until November or December. No Pear will keep long after it is ripe, and this is not sought by the placing in jars, but the retarding of the ripening.

**ORANGE TREES (E. P. B.).**—We should place the trees in the house, and not keep it close, or otherwise give them any stimulus, but defer it until spring. It is likely you will injure the Vines by now keeping the house close and moist, and the Oranges must start into growth late another year from the present being perfected late. If they have not already commenced growth we should throw the house open, and keep them rather dry during the winter, starting in February, and when fairly in growth retub. If, however, they have commenced growth you will need to keep moist for a time, and lessen it as soon as you can after the growths are complete, not retubbing until spring, or until they are fairly in growth. Our advice is based quite as much for the good of the Vines as the Orange trees, and the viney being a cold one will need to be as dry as you can have it to ensure the thorough ripening of the wood.

**PLANTING HAUTOBOIS STRAWBERRIES (Flora).**—So many of the flowers being barren, is a peculiarity of the Hautobois, especially of the old sort. The only kind of Hautobois that can be considered prolific is the Royal Hautobois. Runners should be taken from fruitful plants only, and they may be planted now, but we should have preferred planting six weeks earlier, or so soon as rooted runners could be obtained. They should be planted in rows 2 feet apart, and 18 inches apart in the rows, with the soil well and deeply dug and enriched with manure. Water freely when the plants come into flower, but avoid wetting the flowers.

**SHRUB CULTURE (Idem).**—The spray sent is evidently an Olea, we think *O. fragrans*, which has not attained a size for flowering. Keep rather dry during the winter, not so as to cause the leaves to fall, affording a light and airy position in a greenhouse, and water freely during growth. The chief point to be aimed at is the well-ripening of the wood, and to secure this the plant may, after the growth is complete, be stood outdoors in front of a south wall, and have water only to keep the leaves from flagging. A compost of two parts fibrous loam, one part sandy peat rather rough, and a fifth of silver sand with good drainage, will grow it well.

**COST OF CONCRETE WALK (Rus).**—The price varies with the cost of material, and the carriage to where they are to be used. The lowest prices we know were 9d., and the highest 14d. per square. Consult someone in your locality experienced in such matters, describing to him the work and quantity to be done, which will influence the cost considerably.

**PRUNING POT ROSES (O. S.).**—Pot them now, or at the close of the month and remove to a sheltered situation, placing in a cold pit early in November admitting air very freely. Or they may remain out in a sheltered position with the pots plunged over the rim in coal ashes, and protection given with mats in severe weather. Prune them when taken into the house, if a greenhouse, early in January.

**VIOLA CUTTINGS WINTERING (Idem).**—They being well rooted now, we should transplant them to a sheltered place, planting in rows 6 inches apart, and the plants 8 or 4 inches asunder in the rows, and transplant to the beds in March. That would save you the trouble of wintering in a greenhouse, which is not necessary for such hardy subjects. You might, however, winter the Pansies in a cold frame, but the others are better outside.

**STRIKING CUTTINGS (Idem).**—Bedding Geraniums are best struck in the sunniest place you can command, and so are Felargoniums; but Pansies and most other bedding plants strike best by keeping close and shaded until rooted.

**CHAUMONTIEL PEAR IMPERFECTLY RIPENING (R. S. F.).**—We can only account for the imperfect ripening through your soil being heavy and wet, which does not admit of the fruit being thoroughly matured, hence it ripens "bitter" and speedily decays. This Pear requires a rich warm soil. Probably more efficient drainage of the subsoil would give greater warmth and higher maturity to the fruit. The present year we should not place the Pears in the fruit-room, or only for a short time, removing early in November to a room with a temperature of 50° to 55°, or a warm and moderately dry room and light. The bitterness may probably be evolved during the more speedy ripening process. We think your best remedy will be found in well draining the soil, making it not only drier but warmer.

**ACHIMENES (W. G. M.).**—We cannot name florists' varieties of any flower they are in regions and so nearly alike.

**PEARS FOR SOUTH WESTMORLAND (Le Grand).**—For pyramids and dwarf standards, two of each of the following:—Doyenné d'Été, Clifton des Carmes, Jargonelle, Williams's Bon Chrétien, Beurré d'Amanlie, Louise Bonne de Jersey, Comte de Lamy, Jersey Gratioli, Thompson's and Knight's Monarch. For south wall Duchesse d'Angoulême, Marie Louise, Beurré Rance, and Beurré Dial. Culinary Apples, two of each:—Gallie Odell, Keswick Odell, Cellini, Gloria Mundi, Alfriston, Blenheim Pippin, Dunsdown's Seedling, and Northern Greening.

**CHERRY-TREE LEAVES CATERPILLAR-EATEN (J. H., South Kensington).**—Dust them thoroughly with white hellebore powder, and syringe with water next day. Repeat the treatment if needed.

**SEEDLING PANSIES (Typo).**—They are only suited for borders. They have no special merit.

**NAMES OF FRUITS (Connaught Sub.).**—The Pear is Beurré d'Amanlie. (S.).—Your Peach is not a clingstone, and its leaves are glandless. It is the Early Tilton.

**NAMES OF PLANTS (T. P.).**—1, *Saponaria officinalis*; 2, *Silene Armeria*; 3, *Eupatorium cannabinum*. (J. C. N. and J. O.).—*Datura stramonium*, the Thorn Apple. (G. B.).—Both specimens are insufficient. One seems to be *Arenaria rubra* (*Leipigium rubrum*), the other *Sagina apetala*. (I. H. R.).—We cannot determine the species of *Eucalyptus* from specimen sent. (*A Lady in Chelsea*).—*Catalpa bignonioides*. (S. J. Cow.).—1, *Linum grandiflorum*; 2, *Plumbago europæa*; 3, *Salpiglossis* sp. (W. Bolton).—2, *Asclepias curassavica*; 3, *Tradescantia zebrina*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### DOUBLE BASKETS.

We hoped that the advantages accruing from the use of double baskets would have been so palpable to the committeeman as well as the exhibitor as not to need further comment. We thought that the subject only needed time to set itself right, and to a great extent this has happened. We never anticipated that every schedule would make a rule to allow the use of these double baskets, but we did think that the important exhibitions, the real poultry shows, would carry into effect an arrangement which is of the greatest advantage to all. We have watched with pleasure how many shows have given in and allowed several pens of poultry, as of Pigeons, to come in one package. We do not hesitate to say that Bristol owes a great portion of its 1875 success to this new rule; and we find Oxford, who allowed the use of double baskets last year, but only came to the determination to do so after the schedules were issued, has this year introduced the new rule that "Several pens of poultry may be sent in the same package provided they are properly separated," which is a good proof that they found the plan answer. In the face of all this it is disappointing to find that the best chicken show schedule, on the single bird system, ever issued has kept to the old rule—viz., "Each pen of poultry must be packed in a separate hamper." We expected better things from the Alexandra Palace people, for the names on the schedules are those of men thoroughly *au fait* in all poultry subjects. We write for amateurs, and they are the people who feel this rule so much. The great exhibitors who send their servants with their baskets will never send each bird in a separate basket; but the amateur must either do so or risk the basket being returned or his birds not penned.

Carriage is a fearful item in the account book, and insisting on single birds being in a separate hamper is simply putting so much money into the hands of the railway people, who in return are always ready to be as disagreeable as possible. We cannot see what objection to the plan there can be. Of course all birds in the sale classes must be packed separately; but for other entries, where say the price is £50, so long as there is a rule to the effect, it must surely be an advantage to the show people for two or three birds to be in one basket; and it stands to reason there would be much less trouble in moving about the baskets, and much less space required for stowage.

This is the sort of rule we should like to see inserted in all schedules, especially where they are arranged on the single-bird system, "Several pens of poultry may be sent in the same package provided they are properly separated and labelled; but the price of all such pens must not be less than £50, and every package must have a conspicuous red cross painted on the inside of the lid of the same. All pens entered at less sums than £50 each must be sent in a separate basket."

Now we think some such sort of rule would be a good one. We name £50 as a prohibitive price. A larger or lesser sum can be named at the option of the show authorities, or "not for sale" would, perhaps, answer all ends even better. This, too, would at auction sales save much time which is now needlessly wasted, for no such pen need be put up at all. The red cross would be of great use to the packers, for on opening the baskets they would immediately see the red cross, and would at once know two or more pens had to go into it, and would accordingly search them out and pack them. We suggest this red mark because we have heard some bring forward against the use of double baskets the possibility of only one or two of the birds being packed in the basket when the show is over, and the others which should also have gone into it being left basketless. Now the red mark would at once show this was a package in which more than one pen came, and it would be the packer's fault if the birds were packed wrongly. Those who send their pens at selling prices, or at such prices—say £20 or £25, at which they may be sold, will in the case of this rule being in the schedules only put such prices for the chance of sale, and they will consequently not so much mind paying the extra carriage. So very many birds are sent to our shows which no money would tempt their owners to sell, and this plan would be to them the greatest boon.

We have only to take a catalogue of a fair-sized show and count up the pens entered at £40 and upwards to realise the truth of this, and for such exhibitors to only have to pay half the general railway charges would indeed be a help in the balance sheet. As far as we ourselves are concerned we have worked at a show where the birds came in double baskets, and we can say most positively the trouble they saved was great. We are certain that, once the system got into full swing, the show people would realise the advantage of it as much as the exhibitors, not only in their entries, but in reducing the number of packers, porters, and such-like poultry show hangers-on.

We are greatly pleased with the success of the past few months,

and write in no way disconcerted. We go so far as to call 1874 the year of the "triumph of the double baskets," but we are brought to write this article at the wish of many poultry friends who, finding the old single-package rule in the otherwise magnificent Alexandra schedule, are nervous—not only about the baskets for that show, but lest other schedule-framers, ignorantly copying the rules of their stronger friends, should insert the rule also, and so destroy the work of the past year. Some exhibitors may feel a little anxious about their birds being properly repacked in the double baskets, or of their being sent wrong; to all such we say, Go on with your single baskets by all means, for though the rule may state "several pens may come in one package," it does not say they must, and so only those who themselves approve of the plan are in any way bound to act upon it.

Those who oppose this new system which we are urging may very likely have some minute difficulties to throw in the way, but we feel sure the advantages must entirely flood out the disadvantages, provided the divisions in the baskets are labelled correctly. In conclusion we must say we should be truly delighted if the good Alexandra people will take all we have written in good part and let the fancy know, for it is not at all too late, that several pens may after all come to their show in one properly-divided package at the exhibitor's wish. We feel quite certain they would get more entries, for the place is rather inaccessible from many counties, and the carriage money must necessarily be a high item in the expenses of exhibiting there. To all other societies now issuing or about to issue their schedules we thoroughly recommend them for their own interests to insert some such rule as we propose, as we are convinced that it must be a benefit to all.—W.

### ALEXANDRA PALACE POULTRY SHOW SCHEDULE.

THE opposition Palace has issued its poultry and Pigeon schedule, and the neat little book lies before us. There is a striking resemblance in its "get up" to that of the other Palace, but then the names of the Hon. Secretaries explain this. The Alexandra Palace certainly has commenced in a very satisfactory manner, the list of cups and prizes being a splendid one, and the names of the "management" are those of gentlemen respected and well known for being fanciers of the highest *morale*. We may safely prophesy a good meeting and an unique show of chickens. It is essentially a chicken show, not even the sale classes being open to birds which saw the light before last New year's day. Poultry have eighty-four classes, and twenty-eight cups varying in value from £10 10s. to £3 8s., the most valuable going to the Brahmas. Money may be had instead of plate. The entry fees are the same as usually charged at the Crystal Palace. Of the various breeds Dorkings, Cochins, Brahmas, and Hamburgs are nobly provided for, in some of the classes there being as many as eight prizes. The "neglected breeds" can indeed make this a place of rejoicing—it will be surely a perfect carnival for them. We find three classes for Polish with substantial prizes, two classes for Leghorns, two classes for Malays, one for Silkie, and a variety class with four prizes where Andalusians, Minorcas, and Sultans can play for a good reward. Bantams, too, are well provided for, and the sale classes are numerous with a lot of money spent over them. We shall expect to find many a good bird there; and as all specimens will be put up to auction we shall hope to hear that no exhibitor bought in his birds. Waterfowl and Turkeys have handsome prizes. The Pigeon classes are legion. It should be a superb show of Pigeons, for almost every variety has a class. The Judges are announced, and all good men.

Thus much for this fine schedule. We must not forget to mention one point where it stands out superior to the Crystal Palace—there is no Sunday work for exhibitors. We rejoice we have this great Show over on our side.

There is but one blot on its fair escutcheon, but that one is indeed a bad one—"Each entry for poultry must be packed in a separate hamper." This is positively ridiculous for a single-bird chicken exhibition.

We hope exhibitors will patronise the Show and try to make it a success; and we will endeavour to make the report, which will be found in this Journal of the same week as the Show is held, worthy of the birds we expect to find there.—W.

GREAT NATIONAL POULTRY SHOW at the Crystal Palace.—The Baroness Burdett Coutts, amongst her numerous other kindnesses to protect animals, is anxious to discountenance the exhibition of fowls that have been trimmed in any way, by encouraging those which are shown in their natural state, offers two silver cups for competition. The first will be for the best Game cock, any age, not dubbed or trimmed in any way, silver cup value £5 5s. The next will be for the best cock, any age or variety (excepting Game), not plucked or trimmed in any way,

which will include Cochins or Brahmas with vulture hocks, and Spanish or other varieties, silver cup value £5 5s.

### THE RECENT BIRMINGHAM SUMMER SHOW.

As Treasurer and promoter of this Show I am willing to submit to the subscribers and exhibitors the balance sheet of the third Show held at Aston on August 21st, which I am sorry to say has resulted in a nett loss of over £180, without saying anything of the labours of management, secretaryship, office rent, and numberless sundry expenses. These I am willing to lose, but I really cannot afford to pay the loss. I have four guarantors of £5, and I will give £5 myself in addition to all the expenses of management. This will leave a deficiency of over £105; and I am compelled to appeal to the exhibitors, and especially to those who have been successful, for their assistance in the way of subscriptions to aid me to make up this deficiency.

In originating the first Birmingham Summer Show ten local fanciers shared the liabilities with me, and the Show, though in other respects successful, resulted in a loss of £10 a-piece for us. The next year there would have been no Show had I not taken the responsibility entirely on my own shoulders. It was again a pecuniary failure, and I lost over £70 besides all the trouble, Mr. Piggott and my clerks doing all the work at my expense. This year I determined to make another attempt to establish an annual show, and I called several meetings of the local fanciers and endeavoured to get ten gentlemen to subscribe £10 each. I could only obtain four guarantors of £5 each, but the favourable arrangements I had negotiated with the proprietor of the Aston Lower Grounds induced me in spite of this to try a third time; and the splendid show of birds, splendidly shown, and a loss of £181 are the results.

Our prize list shows 342 prizes. Our exhibitors number 351; if each of these would kindly subscribe a small sum the difficulty would soon be overcome.—JAMES WATTS.

### TOO MANY BREEDS AT ONCE.

"Do one thing at a time and do it well" is a good motto. It has occurred to me that it would do no harm to apply it to poultry-breeding. In looking over your advertising columns one would be led to believe that a man's standing as a breeder depended to a great extent upon the number of varieties he could advertise. I have always thought that the highest excellence in any department of effort depended upon concentration of one's endeavours upon a certain fixed end. If this idea be a correct one, what is the result when a man distracts his attention and divides his efforts among six, eight, or a dozen different varieties? Can he attain the highest excellence in all? The standard of excellence in one breed of fowls cannot be made the standard for any other. For instance, what is excellence in a Brahma or Coochin would be deformity in a Game or Hamburg.

Every breeder should have a distinct ideal type of perfection, or what would be if it could be attained, of the stock he is breeding. How many of us have brains clear enough to conceive a dozen different types and work them out at once? Every man who has ever made a reputation as a breeder has confined his study to one or, at most, two breeds at a time.

Raising fowls and running them is a very different thing from breeding fowls and improving them. I believe that very few men really know more than one breed of fowls. True, many men are good judges of different varieties and breed; when they are brought before them; but this capacity to judge does not prove their proficiency as breeders of all the different kinds. I would object less to a man breeding different varieties of a class than to breeding different classes. There is a strong family resemblance between the different varieties of the Asiatic class, and the same is true of the Spanish class; but where a man desires to attain excellence as a breeder in either class he should omit the other. We do not sufficiently discriminate between the breeder and the mere dealer. To be the one requires study and patience; to be the other, some money and an easy conscience. Is this too sharply accentuated?

If ever poultry-breeding is to become a fine art in this country we must confine our efforts within narrower limits. I confess it shakes my confidence in a man as a breeder when he advertises a long string of specialties. What is a specialty? As I understand the term it should limit the breeder to a single variety. A specialty is a particularity—a limitation to a single thing. How, then, can a breeder have more than one specialty? Can we not do more to improve the poultry in this country by keeping fewer varieties and concentrating all our efforts upon improving them?

Aside from the foolishness of keeping too many breeds, the difficulty in many cases of keeping them pure is very great. I know well-meaning men of whom I would not buy eggs and expect them to hatch true to name. They think their fowls are pure, and never get together nor mix; but I presume many a

good rules that we advise exhibitors to send for a copy of the schedule.

### ST. IVES POULTRY SHOW.

The Huntingdonshire Agricultural Society met at St. Ives. It was a capital meeting, and the quality of the birds exceedingly good. The prizes were handsome, and several cups were given, the competition for which was strong, many of the northern exhibitors coming down to have a try for them. Mr. Nicholls awarded the prizes, and did his work very carefully, and therefore we heard of very little grumbling in any quarter, which is a good proof, for it does not take much in these days to set people off in that direction.

*Dorkings* had four classes, and the quality was very good; perhaps the adult class was the weakest, Coloured were first and second in it, and a nice pen of Whites highly commended. In chickens there were seven entries; the cup fell to a fine pair of chickens in this class, but we should be afraid of the cockerel's toes in days to come. Single cocks only brought two entries, and pairs of hens four; the two noticed pens being really fine-coloured birds. *Brahmas*, Dark, were a nice lot; the first-prize pair came from Creeting. They were exceedingly good, and won the Brahma cup deservedly; second also a good pen. In Lights the first-prize pen contained the cockerel first at Bath, at least we believe so, and here again he looked well; second also a nice pair of birds. In single cockerels or cocks a very fine young Dark bird won easily. *Cochins* made two capital classes; in Buffs a finely-grown pair of chickens won first, but we thought the colour was a little washy; second a good old pen of Buffs. In the next class very fine *Partridge* chickens won the cup; second going to old Whites of great excellence. *Game* had three classes; the Reds were a fair lot. In the Any other variety a very smart pen of Piles won the cup; they were good in colour and head, and very stylish in shape. Single *Game* cocks a fair class of seven birds. *Hamburgs* had four classes, and made up twenty-two entries. The Golden-pencilled were the best as a lot; with the exception of the prize-winner, which were mostly good and properly placed, we saw nothing very striking. A good pen of Silver-spangles won the cup; they were a smart pen of chickens. *Game Bantams* made up a dozen pens, but there was not anything wonderful among them. The first in the next class and the Bantam cup went to a capital pair of Silver-laced. *Spanish* only two pens, and neither up to much. The Variety class was good; a very smart pen of Black Hamburgs winning first, and a nice pen of Oréves second; highly commended good Oréves and Poindes. In the cross-breeds both the prizes went to large birds, evidently a cross between Brahmas and Dorkings; both pens were priced at 10s. per couple.

*Ducks* were very good; *Aylesburys* made a large and remarkably good class, the cup and donation fell here. *Bouens* were good, and must have been a hard class to judge, for in many pens the quality was very even. *Turkeys* and *Geese* were really two very good collections; the winning *Turkeys* very fine indeed. In *Geese* the cup went to Roehdals, and the winners deserved it.

*Pigeons* had only six classes, but the quality was splendid. Strange to say the Antwerp class had only one entry; as a rule this class is one of the strongest in exhibitions, and we cannot conceive why this pen was allowed to run over the course so easily on this occasion. Mr. Baker brought down fourteen pens, and as his reward carried home the donation from the Duke of Manchester for the best pen of Pigeons in the Show and the point cup. Messrs. Yardley and Nottage also sent large and good teams. None of them, however, were able to knock Mr. Walker's pair of Carriers out, and once more they scored first. The Fans were in beautiful trim, and the winners exceedingly good. The Variety class was most attractive, but why Mr. Baker's five pens in this class were all catalogued as "Fantails" history telleth not. We publish full awards below:—

**DORKINGS**.—1, J. Walker, Roehdale. 2, Viscount TURNOR, Shillingee Park, Petworth. 3, W. Morfill, Gooch. *Chickens*.—Cup and 1, Rev. B. Bartrum, Barchampton. 2, Viscount TURNOR, etc. Mrs. E. Wood, Clapton, Thrapstone. 3, R. Chessman, Westwell, Ashford.

**DORKINGS**.—Cock.—1, J. Walker. Hens.—1, Mrs. E. Wood. 2, Rev. B. Bartrum.

**BRAHMAS**.—Dark.—Cup and 1, H. Lingwood, Creeting, Needham Market. 2, W. H. Crabtree. Light.—1, M. Leno, Dunstable. 2, J. Long, Bromley Common. 3, F. Holmes, Farnham; W. H. Crabtree; H. Lingwood. 4, Viscount TURNOR. Any colour.—Cock.—1, G. B. O. Beeson, Easingw. Ware. *Cochins*.—Crown.—Cinnamon or Buff.—1, C. Sidgwick, Keighley. 2, J. Walker. Any variety.—1, C. Sidgwick. 2, W. Whitworth, jun., Longsight. 3, T. M. Darry, Gadeney.

**GAME**.—Black-breasted or other Reds.—1, J. Cook, St. John's, Worcester. 2, J. Mason, St. John's, Worcester. 3, Deacon, Oundle. Any other variety.—Cup and 1, E. Winwood, Worcester. 2, Deacon. Any variety.—Cock.—1, E. Martin, Southorpe, Farnham. 2, E. Winwood. 3, Deacon. *Spanish*.—Any colour.—Cock.—1, S. W. Hallam. 2, H. Pickles, Kirby. Silver-spangled.—Cup and 1, S. W. Hallam. 2, J. Long. 3, H. Pickles. **HAMBURGERS**.—Golden-pencilled.—1, H. Pickles. 2, A. F. Fankner, Thrapstone. 3, J. Ward, Barton Hill; W. H. Crabtree. Silver-pencilled.—1, H. Pickles. 2, J. Long.

**SPANISH**.—1, E. Winwood. 2, S. W. Hallam, Whitwick. **GAME BANTAMS**.—Black-breasted or other Reds.—1, D. C. Wingfield, Sibbury. 2, J. Mayo. 3, Deacon. Any other variety.—1, J. Mayo. 2, Deacon.

**OXFORD POULTRY AND PIGEON SHOW**.—This is on the 27th and 28th of October, and we regret that the Alexandra Park Show is fixed so nearly before it. However, the Oxford Committee will make arrangements to receive pens direct from the Alexandra Park. The Oxford prize list is very rich. Prince Leopold and others give cups, so that altogether there are forty-four for poultry and eighteen for Pigeons. Several pens may be sent in the same package. There are so many new prizes and

duction of the original type. As to the former, it is an established fact, and I quite agree with him. His plan for the latter is very good; and if committees and judges could come to such an arrangement it would, I feel sure, bring fancy Pigeons up to the old standard, which has not been improved upon in this country.

To return to the Jacobin. There is a new point besides the mane now named by some of our friends, which Mr. Weir does not notice. I purposely avoided naming it in my last paper, as I could not admit that such belonged to this bird. That new point is the rose. Until the present year (1875) I never heard of the rose on a Jacobin (the rose is one of the points in the Trumpeter). The so-called rose is caused by the ugly mane, which generally brings the chain to an abrupt termination, often stopping at the side of the neck from this cause. Now the great beauty of the Jacobin is the chain down to the pinions on both sides, or as much farther down as it can be got, tapering off on the lower sides of the breast. The whole characteristics of the head and neck of this bird should be of a rounded nature, all softened off. The hood should not appear to be gummed on to the head, but tilted forward easily and gracefully. The chain, like a lady's boa, divided up the centre over the neck, tapering to points; and the head pleasantly rounded, with a neat, small, well-set beak; and the bird is finished off by a fine taper from the shoulders, caused by the long flights and tail. I say with Mr. Weir that I have not for long seen a Jacobin "I would have as a gift," unless as feeders for young Pouters. They now do well for this purpose, as all cross-bred birds do. I have proved them. Fancy a pair of Red Jacobins bringing up three young Pouters at one time; such was the case with the last I had. They were of the mane and rose type.

Mr. Ure has the credit of bringing forward anew this subject, which must be of great interest to all Jacobin fanciers, and I hope he will give us a few more lines on it, as they may be the means of bringing out the ideas of some other of our friends.—J. HUIE.

### BEE GOSSIP.

HONEY, it may be said, is the ulterior object in apiculture, for a good harvest of it is pleasing alike to both amateurs and bee-farmers. For the last five or six years we have not been favoured with what we call a good honey season. In Scotland and Ireland the bee-keepers have been more lucky than those of England. If the weather be favourable for honey-gathering for a fortnight while the fruit trees are in blossom, and for three weeks while white clover is in flower, bees swarm early and lay up great stores. The clover season generally ends with July; August follows, making, to use the language of royalty, the moorlands "purple with heather." This purple heather yields to bees more honey, or rather yields it faster, than any other plant. When swarms rise in weight to 70 lbs. and upwards on the clover bee-farmers are satisfied. When such hives are taken to the moors they nearly gather their own weight of honey in fifteen days of fine weather. We regret that so few bee-keepers in the south send their hives to the moors.

Every year we send ours to the heather, a distance of twenty-five miles, and on their way to and fro they have to be re-shipped at Manchester. On three seasons of the last six years, while many were lamenting unfavourable results, our best first swarms rose in weight to nearly 100 lbs. each, from some of which we obtained supers of honeycomb weighing 80 lbs. each. Most, if not all, of this was gathered on the moors. Last year (1874) the bees had a good turn on the clover, and went to grouse-land in good condition; but on other seasons of late they were less fortunate on the clover, and had to fill their hives from the heather. Three years ago our hives were so well filled with heather honey that we cut some £30 worth of honeycombs from them without reducing their number. In cutting-out honey from hives kept for stock they are doubtless injured to a certain extent, for the spaces left empty by the comb-knife have to be refilled in spring by the bees, and thus they are hindered from coming to the swarming point so soon as they would otherwise. As a set-off we have "a bird in hand," deeming it good policy to take honey when it can be obtained. If the honey had not been taken that year it would all have been eaten by the bees in 1873, one of the worst seasons for honey-gathering ever known. In a few days our hives will come back from the moors, when the honey will be taken from all that are beyond 60 lbs. weight each. A hive 60 lbs. weight yields about 30 lbs. of honey. In heavier hives there is, of course, a proportionately larger yield of honey.

We would like to encourage all English bee-keepers who are seeking profit to keep large hives, and to send them to the moors every year. Those who resolve to do so will have to use cross sticks in their hives to support the combs on the way. Bar-frame hives, or hives of any kind without cross sticks, cannot be safely carried during the summer months. A Manchester gentleman who has taken a fancy for Ligurian bees has had two stocks sent him from the south by advanced and experienced

apiarians. One of the hives is a bar-framer, the other a common straw hive without cross sticks. Both hives came packed on the crowns in boxes with great care. The bar-frame hive was placed on four yielding indiarubber balls, but notwithstanding all the care bestowed in packing them, all the combs in both hives were shaken loose and detached from their holdings before they arrived, and lay in confused masses. The bees in the straw hive were the best marked Ligurians I ever saw, but they were suffocated and destroyed on their journey. It was sad to witness such injury and destruction. We are sending hives to distant parts, and never have such breakdowns. In a few days we shall send half a dozen hives to a gentleman in Perthshire. All will be prepared for the journey in fifteen or twenty minutes at most, and we guarantee their safe arrival. We simply nail the hives to their boards, ventilate them with fly-proof wire, and send them off in their natural positions without box or basket, or anything else to protect them. Cross sticks in hives are of great value to the bees while they are working, and of great advantage to the bee-master while he handles them, keeping the combs steady and secure on all occasions.

On taking the honey from our heaviest hives we first drive the bees from them into empty hives, and unite them to the bees of those we keep for stock. The stocks are thus strengthened very much, and made strong by numbers. We hear a great deal of talk about managing bees on the depriving system; but any system of management that saves the lives of bees may be termed a depriving system; and one kind of hive is as much depriving as another. The word as used is misleading, and should have no place in apiarian literature. The bees of our honey hives are all united to the stock hives; and the combs containing brood are put into a hive or box, and bees put amongst them to hatch the brood. These brood combs gathered from several hives, and laid in one, yield a large swarm of young bees, which strengthen many hives. The mortar of a building is the least costly, but it gives strength and stability to the whole; and from the refuse combs of honey hives we obtain swarms of bees, which give additional strength and power to hives that have to face the winter storms.—A. PATTIGREW.

### AN APIARIAN TREAT.

ONE of the pleasantest traits to be found among men of science is the hearty good feeling with which they welcome one another for a friendly chat on their mutual hobby, and a sight of the works and collections to illustrate it. Now my hobby, at least one of them—for I have several—are bees, and the occasion of a flower show at Horsham was a good excuse to pay a visit to a friend, Mr. F. W. Cowan, and see his bees and all belonging to them. Now Mr. Cowan is no ordinary bee-keeper, for he manages his bees as well as keeps them to such tune that the *Times* newspaper last year recorded his exploit of obtaining 907 lbs. of honey from twelve hives of bees. Not many people can beat this, so I went to see how he does it.

Mr. Cowan is happily situated in pleasant Sussex. The country around is naturally luxuriant, but not that I could see marvellously favourable to the production of honey. Moreover, the bees are in the town—open country behind it is true, but still there are shops and breweries near, where many workers must be attracted to their destruction. There is one grand feature about Mr. Cowan's bees different from most people's—that is, they are with few exceptions all in houses; not the poky stuffy little places called bee-houses, where the owner cannot get his head into, much more his body, but veritable houses! rooms 20 feet long or more. But I am getting along too fast, so will return to my starting-point, which was from the drawing-room window, into a beautiful well-kept garden, gay with flowers and artistic beds of foliage plants in the highest perfection, which having passed with a cursory glance only, I was introduced to the sanctum sanctorum of the bees, a fine old-fashioned substantial range of stabling, with servants' rooms over. In these latter were the bees, every window having one or more hives, about twenty in all, and every hive a covered way from its mouth to the outer world. If insects have an aristocracy I should say these bees belong to it. No squire of high degree could be better lodged or have more careful thought for his comfort. The hives are all home-made, but none the worse for that, for my friend makes all his own, and is the possessor of a circular saw. Knowing how to use it, it would take a good joiner to beat him in hive-making. The Woodbury pattern is evidently Mr. Cowan's favourite, although he has others. The hives are populous, many having already filled respectable supers, which will figure at our show, and nearly all the others have supers still filling. I should except a Woodbury observatory, which, with its six frames, is as usual unprofitable for honey, but instructive and valuable for observation. Ligurians are greater favourites than the common bee, and such a practical owner has no doubt not given them the preference without due consideration. One objection to bees in rooms that I have found, has been when the crown board is removed the bees fly to the window and are difficult to expel;

but the difficulty was met here by having the window-frame to swing like a fanlight. The bees thus were easily turned outside, and would fly home when no disturbance to the colony was going on. The windows could be closed, and feeding from the ordinary bottle pursued undisturbed by robber bees, and without causing undue excitement.

The secret of Mr. Cowan's success I apprehend is the good housing his bees obtain—thorough ventilation and unceasing care in stimulating feeding; each stock in the autumn is fed up to 80 lbs. contents. The body of the hive and the crown-board is raised about an eighth of an inch, so that a fresh current of air may be always passing through the hive. Some hives have even been wintered with the greatest success without crown-board at all. This bears out what I have before written on the importance of fresh air to bees as well as men. I asked Mr. Cowan if he liked "the quilt" covering, and received the significant answer, "I have tried it, but you see I do not use it." As soon as the severity of winter has passed the bees are transferred into clean hives with five or six of the centre combs, the hive being contracted to fit, and two frames at a time have the knife passed over to unseal all the remaining honey. In this state they are returned to the bees, which rouses them into activity. They seem to believe that spring has arrived, the queen sets about her important vernal business of egg-laying, and the excitement being kept up by a judicious provision of syrup, by the time spring really does arrive the hive has a teeming population ready to take the utmost advantage of fruit blossoms.

Descending to the ground floor we enter a storehouse or museum where all the miscellaneous apparatus of scientific bee-culture seems collected together, as well as hives and supers both in straw and wood; good sound skeps, large and small, with supers and ekes seldom used by our scientific friend, but improved patterns, offered gratis to the cottagers who will condescend to ask for them, in the benevolent hope of teaching them to benefit themselves; well-made, substantial, cottage Woodbury hives, offered as prizes at the flower shows, but which, alas! when won are more often sold than used by the winner; new hives ready for use upstairs when required, all ready for the good time coming. We pass on to the workshop, where we find a lathe, circular saw, and carpenter's tools galore, ready to do duty when required. Here we see a honey-extractor and a couple of pans of honey obtained by its use. This extractor figured at the Crystal Palace Show last year, and was by many thought to be the best exhibited, but I hope to find it beaten this year by the experience gained in the past. My host evidently has an impartial mind, for looking round I see various things which are evidently put aside as not up to the mark, among which are Abbott's frame-bar hive and Addey's column hive, the first with the seams drawn all apart with the weather, and the latter merely a couple of old cheese boxes lined with straw, price one guinea. I fancy buyer as well as hive is sold here.

After viewing a few skeps in the garden whose inhabitants are doomed to transfer to frame hives in autumn we terminate our apianarian treat, and with a passing glance at some excellent Crève-Cœur fowls and a short turn round the garden we adjourn to the house, where I find the same cultivated scientific taste displayed in collections of fossils, minerals, coins, insects, as well as philosophical instruments and cabinets, mostly made by Mr. Cowan's own hand. The sheering strains of the military band at the neighbouring flower show then moved us there, where we found much to admire in flowers and fruits.—JOHN HUNTER, *Eaton Rise, Ealing.*

### OUR LETTER BOX.

**CARRIER PIGEON AT SEA (W. S. and Others).**—It is quite certain that the inscription on the wing feathers must have been moulted off many times since the siege of Paris, but the owner may have renewed it after each moult to identify it as the bird that was then serviceable. We have heard of a Pigeon that had the loving memorial renewed on its wing annually, "Ellen's pet."

**TRANSFERRING BEES (A Beginner).**—First drive your bees out of their present hive into an empty hive. Then take out carefully every comb, and cut squares out of each piece of worker comb only, which you must fit into the frames of the Woodbury hives, so as to reach from the top bar to the bottom of the frames. Secure each comb in its place by narrow strips of wood nailed with tacks or brads to the frames, and crossing each comb in two places on each side. When all the bars with comb are arranged in their places put the Woodbury hive on its stand, and shake the driven bees into it. When all is quiet cover up and leave for a few days, only giving them a little food to quicken them. After a week or so you can take out each comb and remove the narrow strips wherever the combs are securely fixed to the bars. The others may be left on a little longer, or till the spring. This is not a good time to transfer bees unless you are prepared to give them 20 or 30 lbs. of sugar at least, and immediately.

**GOLDEN SYRUP FOR BEES (W. M. E.).**—We have never seen the "golden syrup" as sold by grocers used as food for bees, but as it is a kind of refined treacle or molasses we think bees would greedily eat it if presented to them. When sugar was higher in price than it is now we once saw a swarm put into an empty hive in September and fed with common treacle, nothing else. The bees half filled the hive with combs beautifully white, and were healthy

enough all the following winter. No evil resulted from the use of treacle in this case. By some apianarians treacle and brown sugar are considered too relaxing for bees as winter food. Apart from the question of expense, there is nothing else to fear from its use.

**HIVES (An Old Subscriber).**—We dare not answer your question as to which hives are best. The bee-keeping world would tumble over our heads—that is, all inventors and patrons of specialities in hives would pursue us with maledictions. We prefer and always use ourselves boxes of wood. Some are of an oblong shape to suit our bee house, with large windows on both sides and a small one at the back. They are of common deal. Also we have in use Woodbury bar-framed hives. For profit we should advise you to adopt a good-sized box, say 14 inches square, of inch deal (not red deal), and 9 inches high. This for the main hives. Supers should be smaller every way. As you have a bee house they need no other protection.

**STEWED WATER-CRESS (Annie).**—They should be placed in strong salt and water to free them from insects, then all the water drained off and the cresses put into a stewpan with a lump of butter and a little salt and pepper; a few minutes will suffice to render them quite tender. A little vinegar may be added just before serving, but this must be according to taste. The cress stew made thin, as a substitute for parsley and butter, is also excellent with boiled fowl.

### REMARKS.

8th.—Unusually dark and beginning to rain at 8 A.M.; dark and Novemberish at times all day, but very clear nevertheless.  
9th.—Fine morning; cloudy at times all day, but with bright intervals.  
10th.—A most beautiful day; rather stormlike at 6 P.M., but fine after.  
11th.—Fine morning and very pleasant day, though sometimes cloudy, and at no time very bright.  
12th.—Dull in the morning, and rather so till noon, then bright and fine, but rather cool.  
13th.—Very bright soon after 10 A.M., and all the rest of the day very fine and warm.  
14th.—Another fine bright day, wind rather high and cool, but very pleasant.  
A very pleasant week, dry and moderately bright, but by no means hot. The mean temperature at 9 A.M. nearly the same as last week, but the range less, the nights being slightly warmer and the sun less powerful.—G. J. SYMONS.

### COVENT GARDEN MARKET.—SEPTEMBER 15.

THE supply of common fruits still keeps abundant at last week's prices; but household fruit is quoted at a rather better figure. Of foreign fruits Pines are quite over, but large quantities of Melons and White Grapes are arriving from Spain, as are Pears from France. The Hop season in Kent has checked the supply of Cobs and Filberts, consequently quotations are better.

From observations taken near London during forty-three years, the average day temperature of the week is 63.7°; and its night temperature 44.1°.

## PLANTS FOR OUT FLOWERS AND SPRAYS.

No. 2.

FOR purity of colour, sweetness, and usefulness for cutting from, the "Lilies" (which appears in ancient phraseology to be synonymous with the modern term "bulbs") must take a foremost position; and for fitness the rare, rich, gorgeous, or beautiful Orchids must pale into insignificance, as they, charming though they may be, are not within the reach of more than a few of the cut-flower-like class; but bulbs are within the command of all, and from this fact alone are deserving of first rank in any notes to aid in meeting a demand for cut flowers, inasmuch as among bulbs are some of the most useful for the purpose, and some of which will suit the means and requirements of all.

Some bulbs are hardy, the season of which is prolonged by the adaptability of many for forcing, and others are tender, requiring heat, which is all the claim many, and I must say most, plants have in general acceptance to be choice and rare. A value is put upon some subjects not from any merit, but from the cost entailed in their production. This is not taste, it is not other than setting it aside, knowing the prevailing love for uncommon things; and in this way many equally beautiful and not less suitable subjects are looked down upon, if not rejected altogether, because common. I am forced to this exposition because I shall have occasion to bring before my readers some of the most common of plants, of which the fitness for cutting are unprejudiced by vulgarity or coarseness.

The first plant that I will name is the ROMAN HYACINTH, single white, the flowers of which are delicately scented and profusely produced, each bulb sending up often (not always) three or four spikes of pure white flowers. It may be potted early in September, three bulbs in a 5-inch or five in 6-inch pots in turfy loam, with a fourth of well-rotted manure, and plunged in ashes in a cold frame, covering the bulbs or pots over with about 4 inches thickness of the same material, and left there till early in October, when they may be removed to the shelves of a greenhouse, where they will flower at the close of November or early in December; or they may be had early in November by forwarding in a light airy position in a warm greenhouse. I find if the pots and bulbs are not buried that when the roots are being emitted the bulbs are lifted, or some of them, which the burying material from the pressure upon the bulbs prevents. Bulbs potted about the middle of September and plunged outdoors for a month, then introduced to a greenhouse, will bloom early, or by the middle of December; and bulbs potted the end of September will, if not subjected to a higher temperature than an ordinary greenhouse, flower at Christmas and the new year. Too much cannot be said in praise of this beautiful and extremely valuable plant. It should be grown extensively where early flowers for cutting or plants for decorative purposes are in demand.

No. 746.—VOL. XXIX, NEW SERIES.

To succeed the Roman Hyacinth the PARISIAN HYACINTH is very useful, and potted, say a batch early in September and another at its close, and treated in the same way—i.e., plunging them in ashes for a month or six weeks before placing them in a greenhouse, they will flower in January or early in February, and are very pleasing. They may be had in various colours—viz., French Single White (Lily of the Virgin), French Single Blue, French Single Red (Coeur de Chair). There are also doubles—rose, dark and light blue, but they are not nearly so good as the singles.

Of the FLORISTS' HYACINTH I shall be understood when saying that they in the close spike are too stiff and formal, but some of the long and rather loose-spiked kinds are very useful and effective; and as no spring flower can vie with the Hyacinth, we should not be justified in other than advising their extensive culture for their great beauty, delicious fragrance, grand and varied effect. For cutting from the kinds known as "bedding" should, as they are less costly than named varieties, be extensively grown, both under glass and in the open ground, for succession. Bulbs which were last season grown as pot specimens, and taken care of afterwards, will if now potted be found to give flowers very useful for cutting.

BORDER HYACINTHS.—*Hyacinthus amethystinus*, with its sky-blue bells on a spike about a foot high, is very pretty, doing well in a border of rich loam, sandy rather than heavy. It has the form of the Wood Hyacinth or Bluebell, and flowers at the same time (April), varying somewhat with the season. The *Wild Hyacinth* (*Scilla nutans*), though it may be seen in many places in woods by the acre, and in hedgerows in some places in countless numbers, where the soil is a light sandy loam, at the close of April, is nevertheless very pretty, and is worthy a place in every garden. There are varieties—alba, white; carnea or rosea, rose; and a light-red kind, rubra. They do best in sandy loam, and when wild are most luxuriant where the soil is enriched by fallen leaves, but they will succeed admirably in strong loam.

GRAPE HYACINTH (*Muscari botryoides*), with blue flowers, and the white variety (album) are simply beautiful. *Feather Hyacinth* (*Muscari comosum monstrosum*) has a curious frizzled head or cluster of pale purple flowers, and is useful. The *Musk Hyacinth* (*Muscari moschatum*) is esteemed for its powerful musk perfume. STARCH HYACINTH (*Muscari racemosus*), rather larger than the Grape Hyacinth, otherwise bearing a close resemblance. They flower in March and April, and may be had earlier by potting in autumn, and forwarding in a position near the glass in a light airy greenhouse.

NARCISSUS.—Charming are the Narcissi for cut flowers; they last fresh in a cut state for a long time, the buds opening successively, and are sweetly scented. The whole genus, and it is an extensive one, is deserving of culture from the purity, chasteness, and beauty of the flowers, in combination with a fragrance that cannot fail to please. The flowering season is long, commencing in March and closing in June. There is such a host of species and varieties that I shall name only the most

No. 1408.—VOL. LIV., OLD SERIES.

desirable; not that all are not worthy of a place, but though all are gems, our purpose can be served by the varieties following. *N. bulbocodium* (Hoop Petticoat), which is fine in pots and good outdoors, the flowers golden yellow; and *N. bulbocodium monophylla* (White Hoop Petticoat), which are both very pretty, and the latter as yet scarce. *N. cernuus* (Silver Trumpet), white, is very beautiful, but it pales before the Double White Trumpet (*N. cernuus plenus*). Then the grand *N. pseudo-Narcissus grandipennis* (Double Lent Lily), and the Double Daffodil (*N. Telamonius plenus*), both having very double yellow flowers and large; the Dwarf Daffodil (*N. minor*) being far less, but none the less pretty; and Dwarfest Daffodil (*N. minimus*), with flowers not more than half the size, is very pleasing.

We now come to the *Orange Phoenix* (*N. incomparabilis aurantius plenus*), double yellow, with orange centre; Double Incomparable (*N. incomparabilis*), light yellow; Sulphurkroon (*N. incomparabilis sulphureus plenus*), double white sulphur base, large. These are all very beautiful—the Bush-leaved (*N. juncifolius*), with its bright yellow flowers, charmingly fragrant, being indispensable for association with flowers of less size, it being a dwarf small-flowered species; those fond of the curious will not omit the Cyclamen-like reflexed, dwarf, pale yellow *Narcissus triandrus*. Grandest of the genus is the Double Pheasant Eye (*N. poeticus plenus*), very pure in colour (white), and very sweetly scented. What the *Gardenia* is to the stove this is to the garden, and should be grown in quantity.

Of the *Polyanthus Narcissus*, the Paper White (*N. Tazetta papyraceus*), from its earliness is very valuable. It, and the Double Roman (*N. Tazetta romanus*), white, orange nectary, potted in September, and plunged in ashes outdoors until well rooted, and then brought forward in a light airy position in a rather warm greenhouse, or gently forced, will flower by, if not before, January. The *Polyanthus Narcissus* are good alike for indoor forcing or garden culture, and if not very highly forced, they being flowered in an ordinary greenhouse temperature, and taken care of after flowering, the bulbs flower well in pots a second year. Bathurst, primrose, yellow cup; Bazelman major, white, yellow cup, very fine and sweet; Gloriosa, white, orange cup, and large fine truss; Grand Monarque, white, citron cup, fine flower; Newton, yellow, orange cup, large truss and flower; and Sulphurine, sulphur, light yellow cup, are all good.

The whole family of *Narcissus* are so chaste that no disparagement is apparent in their association with the choicest hothouse flowers, and where cut flowers are in demand there should be representatives of this most beautiful of spring-flowering bulbs planted in quantity. Dainty they are not as to position, thriving well in the open as in partial shade, and in all soils in which stagnant water is not present, but best in rich loamy soil, sandy rather than clayey, and with a well-drained subsoil. In shrubby borders, in shady woodlands or grassy glades they are at home. All that is required is to plant the bulbs with the crown of the bulbs not less than 4, and not more 6 inches beneath the surface, and left to themselves they will continue to grow, flower, and increase.

Of the fairest and sweetest of the *Narcissus* are *Jonquils*. *Camparnelle* (*N. odoratus*), large, single; Double Sweet-scented (*N. jonquilla plena*), and Single Sweet-scented (*N. jonquilla*), are all of easy culture—all with yellow flowers. They require light loam, enriched with leaf soil, and well drained, and sheltered if grown outdoors; but they are chiefly grown in pots, three bulbs in a 5-inch, or five in a 6-inch pot, and treated like *Hyacinths* flower well in February onwards, being gently forced. The *Jonquils* have grassy leaves, and are fine as pot plants. Beds of *Jonquils* ought to be in every garden, the bulbs being planted 8 inches deep, and 4 to 6 inches apart, and not disturbed oftener than every third or fourth year.

All the *Narcissus* should be planted in October, and not later than early November, though it is becoming a practice to plant successionally, or as late as early January, with a view to later bloom. The bloom is, however, so long continued by growing the several varieties above named, that a succession of *Narcissus* bloom can surely be had during a fourth of the year without having to plant at times which tells disastrously upon the after well-doing of the bulbs.

**TULIPS.**—Beautiful and effective as these are for the garden and house decoration in the early part of the year, we are compelled to own they do not come up to the excellence required in a cut flower. Still they have brilliancy of colour, which may or may not be gaudy, just as some estimate bright-

ness and high colour; and whatever we may think of them when expanded, we are compelled to own them very telling in the bud state. The flowers of the *Duc Van Thol* are very gay and sweet. By potting early in September, plunging outdoors in ashes, or what is better, cocoa-nut fibre refuse, and introducing to gentle heat about six weeks afterwards, they may be had in flower at the close of November or early December. Expanded blooms are not chaste. These remarks apply to the singles. The doubles of course tell best when expanded. As I am not advising their extended culture for cut flowers, I need not trouble you with names, only the *Duc Van Thol* in its varieties among the singles, and *Blanche Hative*, *La Candeur*, *Rex rubrorum*, and *Tournesol* of the doubles, may be useful.—G. ABBEY.

## INTERNATIONAL EXHIBITION OF FRUITS AT GHENT.

A GREAT International Exhibition of fruits was opened at Ghent on the 20th inst., and formed one of the series of *Congrès Pomologique* of the *Société Pomologique de France*, which have been held annually in various places for a number of years past. In carrying out the meeting at Ghent the Society has been ably supported by the *Cercle d'Arboriculture*, who have come forward in support of the project with the energy they always exhibit in everything concerned in the advancement of the interests of horticulture and arboriculture. The result of the united efforts of these two bodies is a show of fruits representing the pomology of Belgium, such as, perhaps, has never been gathered together before. In the country of Van Mons, Bivort, Hardenpont, Esperen, and Grégoire, one naturally expects to see pomology in its best and brightest aspect, and in this case the expectation has not been disappointed.

The Exhibition, which is truly international, is held in the great hall of the Casino, a place familiar to British horticulturists for many years as the shrine of Flora and Pomona in Ghent. The whole extent of that space is furnished with thirty-five large tables completely covered with fruit. These consist principally of Apples and Pears—the season getting late for the "soft fruits," and the duration of the Show for a whole week being unfavourable to the exhibition of these in good condition.

These exhibitions of Peaches and Plums which are present are consequently very limited, and their condition not of the best. Among them we saw nothing that was new. Next in importance to the Apples and Pears, of which there is an enormous quantity, Grapes form the great attraction. In this class our countrymen, Messrs. Lane & Son of Berkhampstead, take the first rank, and were awarded the gold medal for fifteen varieties grown under glass. These gentlemen also received (*avec acclamation*) the silver-gilt medal for eight varieties grown under glass. These productions of Messrs. Lane & Son are familiar to our readers by the honours they have repeatedly obtained at our exhibitions at home. In the class for eight varieties M. Ambrose Verschaffelt, who in his retirement has not abandoned his former love for horticulture, is second with some good bunches, among which is a very good one of Foster's White Seedling. The second in the class of fifteen varieties is the Baroness van Loo-Malfait of Evergem, and these, too, are well grown, and would have formed fine large bunches if they had not been too much thinned. Certainly the best-cultivated of all the Belgian Grapes were those of Dr. Centerick of Audenarde, who received the silver-gilt medal for the best collection of twelve varieties grown under glass, and especially the bunches of *Muscot* Hamburg, Bidwell's Seedling, and Dutch Hamburg showed great skill and judgment in their cultivation.

Of the Grapes grown in the open air the finest collection was from M. Beeson of Marseilles. This consisted of varieties many of which were wine Grapes, and to this collection the gold medal offered by the city of Ghent was awarded. Among them we observed many of those that are cultivated in the vineries of England, and remarked what has often been stated before, that even in the land of the Vine Grapes are grown in a manner much inferior to what they are when produced under glass and with applied skill in England. Of the other exhibitions, whether it is that Melons are not relished by the Belgians, or that they are enamoured of a particular class of that fruit, we do not know, but of all the fruits that were exhibited we saw nothing which was so inferior in quality as the kind of that fruit. In England, as is well known, the Melon forms a very important article of cultivation in every well-regulated garden, and the skill bestowed upon its production is an object of rivalry among all our great gardeners. Judging from what we saw at Ghent this does not appear to be the case in Belgium. At this

season of the year in England, if a prize were offered for the best collection of Melons, the Show would be inundated with them, but here the class was vacant for want of competitors. There were a few Melons exhibited in general collections, but they appeared to be varieties of a common description—a sort of Cantaloupe with the deep longitudinal furrows down their side, and with the firm red flesh. We would commend the high cultivation of the Melon to our Belgian friends, and advise them to procure from England seed of such varieties as Beechwood, Golden Gem, Victory of Bath, Reed's Scarlet Flesh, Scarlet Gem, Trentham Hybrid, and others, which would revolutionise the culture of the Melon in Belgium; and if a little attention were paid to their cultivation, as has been done during the last few years to the culture of Grapes under glass, our friends will find that they have added another pleasure to their lives.

The largest and best exhibition of miscellaneous fruits sent by a private individual was that of Messrs. Baltet frères of Troyes. This occupied two very long tables, and contained admirably grown specimens of numerous varieties of Apples and Pears. The most remarkable specimen in this collection was a fruit of the Apple Managère, which measured 1 foot 7½ inches in circumference, and weighed upwards of 1 lb. 1 oz. A very large and fine collection came from the Société Centrale d'Agriculture de Belgique of Brussels, among which were remarkably fine specimens. But it would be needless for us to go farther into particulars than we have done. The Show is a very extensive one, and the collections are necessarily very similar, the classes varying only in the quantities which constitute them; and it will give some idea of the extent of the Exhibition when we state that it embraces upwards of twelve thousand dishes of fruit of all kinds. To specify in a report which must necessarily be short any great number of these would be impossible and to a certain extent unprofitable, for, as we have already said, the varieties exhibited are so often repeated in the various classes, that to do so would be to go over the same ground again and again. But before concluding we must notice a very large collection of seedling Pears shown by that indefatigable and successful raiser M. K. Grégoire-Nelis of Jodoigne, and to which the gold medal offered by the King was awarded. These were all shown under numbers, and as no names were yet given we cannot specify them.

We shall now conclude this notice of the Show by giving an outline of the schedule. It is divided into seven sections—First, miscellaneous fruits, and the highest honours here fell to Messrs. Baltet frères of Troyes for the collection already noticed, and to which the medal offered by the Royal Agricultural and Botanic Society of Ghent was awarded; the second, consisting of a gold medal, falling to M. Hago Courtrai and M. de Ghellinck de Walle of Wondelgem. The second section was for Pears; and for the largest collection of all kinds the gold medal, offered by the Federation of the Horticultural Societies of Belgium, was awarded to M. J. L. van Leekwyk of Antwerp. For the best hundred varieties of dessert Pears the first prize was awarded to M. V. Biebuyck, President of the Horticultural Society of Courtrai; for the best seventy-five varieties to M. Struelens of Grammont; and for the best fifty varieties to Count de Kerchove de Denterghem, Burgomaster of Ghent. The third section was for Apples, and for the largest collection the gold medal offered by the Government was awarded to M. Hago of Courtrai. The fourth section was for stone fruits, and as we have already said the exhibition was in these so weak that we shall not further remark upon this section. The fifth included Grapes, on which we have already commented. The sixth for miscellaneous other fruits brought no competitions; and the seventh was for various objects, including implements, &c., among which we saw nothing differing from what one usually meets with on similar occasions.

OCCASIONS such as these horticultural exhibitions would not be complete in Belgium if the pleasure and comfort of the visitors were neglected. The hospitality of our neighbours, which has become proverbial, was fully indulged on this occasion, and a series of banquets and excursions were projected and carried out, which contributed very much to the enjoyment of the occasion. Here follows the programme, which is enough to satisfy the most craven appetite:—

Sept. 19.—Nine o'clock, work of the Jury. Twelve o'clock, opening of the Exhibition. Two o'clock, banquet to the Jury. Five, concert at the Zoological Garden.

Sept. 20.—Reception of members of Congress at the Hotel de Ville. Twelve, installation of the Congress at the Casino. One, visit to the gardens of Count de Kerchove de Denterghem. Five, concert at the garden of the Casino.

Sept. 21.—Nine, sitting of the Congress. Two, visit to the gardens of the Baroness van Loo-Malfait and of M. J. de Poorter.

Sept. 22.—Nine, sitting of the Congress. Two, visit to the gardens of M. Jules van Loo and of M. de Ghellinck de Walle.

Sept. 23.—At nine, sitting of the Congress. At two, visit to the gardens of Meester de Ravenstein. At five banquet to Members of Congress. At eight, a concert at the Royal Society of *Mélanes*.

Sept. 24 and 25.—Continuation of the Congress and visits to the horticultural establishments of the city.

### TAKING-UP AND STORING POTATOES.

It is with much surprise that I have observed a general tendency to revert to the obsolete and useless practice of pulling the haulm from Potatoes to preserve them from blight. The plan is utterly worthless, and is a mere compromise upon the part of those who will not be convinced that the tubers may be taken up while the haulm is green in perfect safety without suffering the slightest deterioration in quality. The whole of my Potato crop has now been in the storehouse for upwards of a month. In quantity it amounts to about sixty sacks, and in quality is of more than average excellence. There are the tubers now exhibiting a little roughness upon the skin, it must be granted, but as firm and plump as could be wished. Let it rain, say I, and make the late-sown Turnips, Celery, and winter Greens grow, the late autumnal fruit to attain the fullest perfection of size and maturity, and an abundant herbage spring up in parks and meadows for our flocks and herds.

Those persons whose Potatoes are spoilt by rain this year deserve to suffer, for never was there a more propitious season. The crop sustained no check during its growth, frequent showers maintaining it in fullest vigour. As it attained full growth dry weather ensued; the ripening process went steadily on, and when it was taken up the soil was literally dust-dry. Much of the foliage was already of a dull brown and yellow tinge, and the tubers parted freely from the haulm. But the skin was much rubbed in the process of collecting and conveying the Potatoes to the storehouse, and this is the rub—this the stumbling block which Messrs. Dull and Dawdle cannot get over. Let me assure them that those of us who have now for several years adopted the early-lifting method, and thus escaped the ravages of disease, can no more afford to indulge in rash or speculative theories than they can. We are bound to succeed where success is possible, and in order to do this we strive to understand and avail ourselves of every advantage placed in our way by nature or science, applying such lessons with all due caution, but never hesitating to do so thoroughly when experience proves us to be right.

At the time of writing this (September 14th) I am fully aware that in my own neighbourhood the greater part of the Potato crop still remains in the ground. Almost all the haulm is dead, glorious weather prevails, and yet nothing is done. One can only conclude that those who so positively court failure have no right to complain when it comes, and to such I have nothing to say. Nor did I suppose it would be necessary to repeat to really practical men former statements in favour of the early-lifting process, when its immense advantages must be so patent, and especially when such men as "D., Deal," Mr. Wright, and many others, had also borne testimony to its value; but when it is gravely asserted that the disease may be avoided by pulling the haulm from the tubers, and leaving them in the soil, it becomes a positive duty to speak out.

As confirmatory evidence of the value of timely lifting I append an extract from a letter received this morning:—"The Potato yield is fine and abundant; I have 120 sacks housed, free from blight and in excellent condition."—EDWARD LUCKHURST.

### CROPS IN NORTH LANCASHIRE.

WITH the exception of a heavy flood at the beginning of this month we have had glorious weather in the northern districts during September, a second summer in fact, with a temperature ranging from 65° to 70° in the shade. This has done splendidly for the ripening of fruit, and the memory of man cannot reach back to a year of such plenitude of fine and well-ripened fruit. Fruit which, in other years, would have afforded matter for newspaper paragraphs is now completely unnoticed, from the simple fact that such is grown in every garden or orchard. Cabbage, Broccoli, in fact all garden produce, is very plentiful and remarkably well grown. At the recent Show of the Ulverston Horticultural Society, an old-established one, the judges remarked that never before had they witnessed

so fine a display of vegetables. Potatoes are exceeding our expectations, and very few diseased tubers are now being taken up. Market prices are 5d. to 6d. per 14 lbs.—BETA.

## STRUCTURES FOR FORCING AND PROTECTION.

### No. 2.

In a previous communication on page 200 I endeavoured, in reply to many inquiries, to submit in a concise manner some of the most simple forms of protective structures. A batch of other applicants seeking instruction suggests that something more than mere shelter is needed. The great majority covet something that is simple yet useful, economical yet efficient. They not only require structures which with much covering and great care will keep their bedding plants alive during the winter, but they wish to keep them in a comfortable and healthy state. To this end fire heat must be afforded in some form or other, for, as a means of winter protection, heat from fermenting material, as manure and leaves, can seldom be relied on. That heat is too moist, and subject to fluctuation by weather changes that, however valuable it may be in spring, it is not adapted for employment in winter.

Hot water is now the orthodox medium of heating glass structures, and withal it is the best medium, being sweet,

winter the soil is removed, and a lattice-work trellis is placed for bedding plants. It is admirably adapted for its purpose, and is inexpensive and substantial.

Fig. 59, though perhaps more showy, is still more simple, the flues being built in the walls; the fire communicating with the front, crossing one end, and continuing along the back flue. In this pit bottom heat, when required for Melons in the summer, is afforded by manure and leaves, and excellent crops are produced; *a* shows the soil, *b* the manure, *c* the trellis, and *d* the flues. In the autumn the soil is removed and a flooring of boards introduced, when bedding and greenhouse plants are safely and healthfully kept. These simple flue-heated pits are valuable adjuncts to any garden where means of heating by hot water is not provided and cannot be obtained.

The next figure is more pretentious; it is a section of a span-roofed house heated by flues. The flues are made to furnish both top and bottom heat, and between them are chambers (*a c*) which communicate heat to the beds *b b*. The flues are partly under the beds, to which they communicate heat by the

Fig. 58.—Heated Pit.

certain, and well under command; but as more than one correspondent expresses himself, "to wait until a boiler and hot-water pipes, is to wait an indefinite time," and he also wishes to know if "something cannot be done by a flue." I reply that a great deal may be done with a flue. A great deal has been done, and is being done, by the aid of this primitive mode of heating. Some of the best Black Hamburg Grapes that I have this year seen were produced by flue heat; and I have not seen a better house of Cucumbers than have been produced with the aid of the flue as the sole means of supplying artificial heat. But it is not because of what I have seen that I speak a word in favour of flue-heating, but because my own experience has afforded me proof of its usefulness. I say this for the benefit of those who desire heat in some form, and who cannot obtain a hot-water apparatus, but who yet can manage to have a flue erected.

Some years ago Mr. Abbey submitted plans by which I benefited. As near as possible I will reproduce them for the benefit of others. Fig. 58 is a very simple form of pit. It is shown with two flues, or rather one flue commencing at and running underneath the bed for bottom heat, and continuing along the front for top heat. The chamber *a a*, covered with

Fig. 60.—Flue-heated House.

spaces left between the flagstones and the sides of the beds, as well as by the chambers *a a*; whilst top heat is afforded by the sides of the two centre flues, and the heated air ascending from the openings *c c*. This house is adapted, if the beds *b b* are filled with tan, for plant-growing, or if filled with soil for Cucumbers, Melons, or pot Vines. When I say pot Vines I mean fruiting canes which have been grown in pots and then planted out to produce their fruit. By that simple mode very large crops of Grapes may be obtained, and to those who have seen them it is a matter of surprise that the bedding-out system is not more general. In the hands of amateurs especially it is more easy and satisfactory than fruiting the Vines in pots.

But while admitting the great usefulness of flues preference is given to hot water, and it may be useful to place the two systems as adapted for the same purposes side by side. Fig. 61

Fig. 59.—Flue Melon Pit.

flagstones, affords heat for Cucumbers in spring. In the

Fig. 61.—Hot-water Pit.

shows an ordinary pit heated by two hot-water pipes, *a a*, for bottom heat, which are surrounded by rubble, such as half bricks, &c., from 6 to 9 inches of the same being placed above them; the rougher parts of the compost are then put on, or a layer of charred turves an inch thick, so as to prevent the finer soil from passing into the rubble, and on that from 10 inches to a foot of soil, *b*, in which the Melons or Cucumbers are planted in the centre of the bed. They are trained over the soil in the same manner as those in dung frames. There are

two 4-inch hot-water pipes in front, at *c*, to maintain the proper degree of atmospheric heat, the soil being kept from them by a slate on edge, *d*. *e e* is the ground level. Except in being heated by hot water the pit does not differ from an ordinary one. In the winter the soil can be removed and boards or ashes introduced for affording convenience for wintering plants. That useful pit is also adapted for growing Mushrooms after the summer crops are removed if it is not required for plants. The surface in that case will need to be covered with hay. Another pit (fig. 62) has been submitted

Fig. 61.—Hot-water Pit.

by Mr. Abbey, but as I have not myself had actual experience of it, I will submit that cultivator's remarks:—Fig. 62 is "the end section of a pit heated by hot-water pipes, differing little from the preceding, except in the bottom heat being supplied by two 4-inch pipes to a chamber, *a a*, the soil being supported above by flagstones, which also form the upper cover of the hot-air chamber; two of their ends and sides rest on the outer walls, the other on pillars of brick or stone as *c*. The flags are not laid in mortar, but have the joints open. A few inches of rubble placed on the flags prevent the joints from becoming choked with soil. There are two 4-inch pipes in front for top heat; *c* is the space for a thickness of 1 foot of soil, and *d* the space for the plants; *e e* is the ground level. This mode of furnishing bottom heat by hot-air chambers is preferable to placing rubble over the pipes as in fig. 61, or soil immediately in contact with the pipes. The heat is more equable by the chamber system, and communicates to the soil above a much lower temperature; but the heat is greatest by the other plan immediately above the pipes, whilst the remaining parts of the soil are nearly cold. By the chamber system there is a large volume of heated air of an equable temperature throughout, presenting the same evenness as a bed of fermenting materials."

I now take one more step in advance to note a house which was erected for Melons, and which has afforded a great supply, not of Melons only, but Cucumbers, Figs, and Grapes. It has also been of immense assistance in plant-growing, and is in fact one of the most useful of structures for a garden of moderate requirements. This is simply a house with a half-span

Fig. 62.—Half-span Melon House.

roof. Bottom heat is supplied by two 4-inch hot-water pipes to a chamber *a*, and top heat by two pipes in front, and one to the left of the path in the centre of the house. *b* is a bed of soil. There is a trellis at *c*, and a bed at back (*d*) which is very useful for plants, yet of no value for Melons, but will grow Figs or Grapes, the latter in pots. Bottom heat is furnished to it by a hot-water pipe, *e*, covered with rubble.

In submitting these plans let me thank Mr. Abbey for the advice that many years ago he afforded me. I can now attest to the usefulness of these several structures. Their value has also been seen by others who have required plans. With the Editors' permission I now furnish them, being satisfied that as they have served me well that they will be also equally serviceable to others who are making inquiries for useful aids for protection and forcing.—COMPILER.

### NOTES BY THE WAY.

In going about on matters not connected with horticulture but with my own profession I contrive to pick up a few stray notes, which interest myself, not, perhaps, worthy of occupying a place separately in our Journal, but which strung together may have some little interest for a part of our readers. I paid my annual visit to Cheltenham in August, and both there and on my way home had an opportunity of stringing together some of these notes. Could I be at Cheltenham and not pay a visit to Mr. Cypher, who has so wonderfully come to the front as a planteman, showing what a real love for flowers can do, even although there may not be the benefit of a previous training? I had a run through his houses, and there saw the plants which have already done duty and were now being nursed and brought on to enter the campaign another year. Amongst other plants which he does so well, and which one rarely sees now-a-days, is that fine old stove plant *Gloriosa superba*. What can exceed its quaintness and gorgeous beauty? And while many a plant with not one-twentieth part of its claims to beauty is nursed and potted simply because it happens to be a novelty, *Gloriosa* remains, except in a few places, utterly neglected. Here it was very beautiful. The *Allamandas* were full of bloom and making grand growth; indeed, the same might be said of all his plants, and I doubt not we shall hear something more of them next year.

Dr. Abercrombie's garden in Suffolk Square was again interesting, notwithstanding the very unfavourable season. In his dry sandy soil very many things had failed, but his ribbon border was very fine, and he is evidently in the way of giving us some good things in Carnations and Picotees. We are already indebted to him for some of the best self-coloured varieties we have, for Maiden's Blush, King of Yellows, and Géant des Batailles cannot easily be beaten, and he is now striving in the way of florists' varieties. A Carnation raised by him and named Duke of Edinburgh, a fine scarlet bixarre, was sent out by Mr. Turner last year.

On my home journey I stopped at Reading and had the pleasure of seeing the establishment of the Messrs. Sutton, of which I have more than once written in the Journal, whose readers need not be told of the extensive character of the establishment and of the singularly complete arrangement of everything connected with it. And yet why say complete? I thought when I saw their new buildings last year that everything that was needed even for their colossal business had been done. What was my surprise, then, to find their excavators at work, and to hear that they had more builders' work on hand for the next two years than they had as yet undertaken. The first of these works is the erection of a store 240 feet in length mainly for their farm seeds and Potatoes; then their lecture-room is to be altered, and the "British Workman," a coffee house which they have erected for the benefit of their workpeople and others, and which has proved a real good to many. Time did not permit me to do more than visit Sutherlands, the seat of Mr. Martin Sutton, jun., where I saw one of the very best orchard houses (a lean-to against a wall) that I have ever seen, where the trees planted out were laden with fruit, and where alongside the walks a number of Tea and Noisette Roses had been planted and trained on wire, giving in the earlier months of the spring a splendid harvest of flowers. It is in such cases that the orchard house becomes really a great advantage—very unlike some that I have seen, where the plants grown in pots looked unhappy, want of watering being, I think, the cause from which they most suffer under such circumstances; but planted-out orchard houses, such as I saw here, seem to give us all that we want without the expense attendant on boilers and pipes.

From Reading I passed on to Slough, and who ever visited the Royal Nursery that did not find something worth looking at? We southern florists owe much to Mr. Charles Turner. But for him the *Auricula*, *Pink*, *Carnation*, and *Picotee* must have gone out of growth amongst us. He has fostered them

from sheer love of them, for his space and the time of his men could assuredly be occupied with things that would pay him better. But he has clung to their culture through pure love, and has exhibited them where no prizes could be obtained simply to show people what lovely flowers they were neglecting. The fine stock which he raises every year finds its way, however, mainly to the midland and northern parts of the kingdom, where certainly florists' flowers are more at home than in the south. I was here much interested in seeing some rows of what I believe will be found to be one of the very best Peas in cultivation—Dr. Maclean, so named by Mr. Turner to commemorate the name of a raiser to whom we are indebted for Little Gem, Princess Royal, Advancer, Best of All, &c., some of the best-flavoured Peas we have. Its productiveness is something wonderful. I saw it when two crops had already been gathered, and yet the pods there hung as thick as on an ordinary Pea. Mr. Turner, than whom there is no better judge, says it is an excellently flavoured Pea. It is about 3 feet high, and literally covers itself with pods from top to bottom. There is one thing I never cease to regret when going to Mr. Turner's in the autumn—viz., that he has abandoned, save in the matter of seedlings, the cultivation of the Dahlia. We miss his highly finished flowers at the exhibitions, and I can only hope that he will some day resume its culture.

Need I say that every department exhibited the care, skill, and neatness which always characterise this nursery? It is no light matter in such a season as this has been, and with the perplexities of the labour market, to keep a garden neat; but it has been done here. The pot Roses, Azaleas, Camellias—all, in fact, were in the rudest health; and the fine collection of Auriculas shaded by a fine row of Poplars were in snug summer quarters, giving promise of a fine spring bloom. By-the-by, why are not these Poplar hedges more used? I saw a grand lot of them at Mr. Ware's at Tottenham, and there is nothing where shade is required that makes a more effective hedge. Foreigners would perhaps laugh at us in England (where the greater number of them believe that the sun rarely shines, and that we are enveloped in fog for months together) for requiring shade; but in many of our southern counties there are gardens where it is most difficult to obtain it, and in such places no quicker or more effective hedge can be had than that composed of the Lombardy Poplar.—D., Deal.

## GREAT INTERNATIONAL FRUIT AND FLOWER SHOW AT EDINBURGH.

In submitting a report of this great Exhibition last week, we could necessarily not do more than give a brief record of the successful exhibitors in the most important classes. In that report a few unimportant errors had crept in in transmission by electric telegraph. It is only necessary to correct two. Mr. Hunter was made to be the winner in "light" varieties of Grapes; it should have been "eight" varieties; and Mr. Mathieson was awarded the Veitch Memorial medal for the best stove plant; the report was otherwise correct. Our further remarks will be commentary, descriptive, and supplementary.

The Exhibition was held in the Music Hall and Assembly Rooms, the plants in the former, and the fruit in the latter portion of the same edifice, but only a glance was needed to show that the Exhibition had quite outgrown the space which the large building afforded. The managers did their best—did, indeed, all that energy and skill could do—yet it was impossible to prevent undue crowding of plants, fruit, and visitors. We greatly fear that had southern managers to deal with the same amount of produce with the same limited means of staging it, that the Exhibition would have resulted in a failure, whereas in spite of the crowding this great gathering was a great success.

This success was directly contributed to by the energy of the Secretaries, Mr. Stuart and Mr. Young; and to Mr. Dunn, Dalkeith; Mr. Downie, West Coates; and Mr. Lamont in the plant department; and to Mr. Thomson, Clovenfords; Mr. LeClead, Newbattle; and Mr. Anderson, Oxenford Castle, in the fruit section. These are men who refuse to fail, and they averted failure by a determination to work the whole of the night, and to have all in readiness for the Judges by six o'clock of the morning of the Exhibition. This resolve was carried out, and the Judges were promptly at their duties at that early hour. The room was dingy, but by carrying the Grapes, &c., to the windows the work was persevered in, and the awards were attached before breakfast. This energy was most commendable, and one could not help wondering why a plan in all respects so good should not be adopted and carried out in all exhibitions of magnitude and importance.

The system adopted, too, was of the simplest, and the same, we believe, as that which is carried out at the Crystal Palace.

It is this: Each exhibitor's name is legibly written on the card which denotes the class in which he competes; this card is turned down and the class and exhibitors' numbers are written on the back of it, and the Judges give the awards to the respective numbers. An assistant, who has ready printed slips of "first," "second," and "third" prizes, turns over the cards and affixes them, and the work is done. For perfect fairness, smoothness, and celerity no system can be better; and by the side of it the plan of exhibiting under numbers and the consequent delay ensuing, to say nothing of its unpleasant suggestions, sinks into insignificance.

This early judging and prompt attachment of the awards enabled another most worthy plan to be carried out—of admitting gardeners, on payment of a shilling each, to inspect the Show during one hour and a half before the public admission at 11 A.M. The eagerness with which the gardeners availed themselves of this privilege proved how much it was appreciated. It seems almost incredible, but we state it on good authority, that £40 were taken in gardeners' shillings within the first hour of their admission. What earnestness and interest does that portray! and what sympathy it must call forth—it cannot be otherwise—between the managers of the Society and the men who are the mainspring of the success of that management! What a stimulus this reasonable concession must be to young gardeners who are permitted to enjoy a critical survey of the exhibits in their first fresh state! and what encouragement it is to more experienced men to feel that their efforts are appreciated and their position officially recognised in such a graceful and substantial manner! On grounds both of justice and policy this plan is commendable, and we draw attention to it as one of the most gratifying as well as one of the soundest features of management of this great Show. Another feature we must notice which is worthy of general adoption, and that is the payment of the prizes on the first day of the Exhibition. Such promptitude fosters confidence, creates sympathy, and in no small degree promotes success.

Judging, we have said, commenced at 6 A.M., and in half an hour afterwards we were enabled to quote the awards and note the characteristics of the successful products. This early judging contributed in a great degree to the success and enjoyment of the Show. It is an immense improvement on the old and too common system of not completing the awards until mid-day. The clumsiness of the latter plan was very apparent when thought of in connection with the business-like efficiency of the former.

The judging and weighing of the elephantine bunches was an exciting moment. Mr. Curror's compact bunch was marked by the grower as weighing 26 lbs. 4 ozs. It was transferred to the scale, and a shout ascended when the result was seen. In the excitement of the moment the weight was variously announced, one shouting 26 lbs. 1 oz., another 26½ lbs., and a third 26 lbs. 4 oz., but the official record was, we believe, 26 lbs. 4 ozs., and the Judges awarded the prize to this as the heaviest bunch of Grapes which the world has ever produced. The Vine was planted by Mr. William Thomson of the celebrated Clovenfords Vineyard, and carried, besides this monster, three other bunches, one of which weighed 18 lbs., and received one of the Veitch Memorial medals. The 26-pounder was a remarkably compact heavily-shouldered bunch, tapering to a point. It was very full and the berries good, thinning having been done with great care. Mr. Dickson's bunch, represented as weighing 25 lbs. 15 ozs., was apparently much the greatest in point of size, and as seen with its ponderous shoulders tied out covered an immense amount of space. The berries of this were finer than those of its great rival. It had clearly been overthinned when it is considered that the prize was for weight and not for quality. In the production of bunches in which weight is the primary consideration, it is clear that there must be little or no thinning of the berries. This was a forked bunch, but yet not unsightly. We shall next week be able to present an engraving of this gigantic bunch of Grapes from a photograph taken when it was hanging on the Vine. Owing to the extraordinary pressure of visitors it was hardly possible to make a critical examination of these bunches; they appeared, however, to be perfectly honest specimens of cultural skill, and if we judge them, as we must do, by the characters of the men who produce them, we must accept them as *bond fide* productions unparalleled in the history of Grape culture. In such a contest it was honourable to lose, but to win a triumph indeed.

The next great contest was for eight varieties of Grapes, won by Mr. Hunter. These were huge massive bunches of Gros Guillaume, Calabrian Raisin, Buckhardt's Prince, Muscat of Alexandria, Alicante, Royal Vineyard, Gros Colman, and Trebbiano. These bunches would range from 5 to 8 lbs. Mr. Johnson's (second prize) were smaller bunches, but the berries were, perhaps, finer, and the finish superior to the preceding. In this collection was a handsome example of Duke of Buccleuch and a grand bunch of Muscat of Alexandria, which worthily won a Veitch Memorial medal. Mr. Reid's (third) contribution was also of very high quality, the berries of Golden Champion being

pure and spotless, those of Gros Colman being of splendid size and finish, while the bunch of Mrs. Pince's Black Muscat was probably the most perfect ever exhibited; it was large, even in berry, and almost jet black to the stalk. Dr. Hogg and Mr. W. Thomson awarded a Veitch medal to this extremely meritorious bunch, of which it was eminently worthy.

The cup offered by Messrs. Boyd & Sons, Paisley, for six varieties of Grapes, brought forward some extremely fine collections. The competition between Mr. Stewart and Mr. Hunter was very close, quality, however, triumphing over size, and winning the cup for Mr. Stewart. Noticeable in these collections was the beautiful finish of Mrs. Pince, Muscat of Alexandria, Black Prince, and Black Hamburgh in the cup collection, and the ponderous bunches of White Tokay, Calabrian Raisin, and fine examples of Alicante and Madresfield Court from Mr. Hunter. For this collection a special prize was awarded. In this class valuable collections were staged by Mr. Bruce, Chorlton, Manchester, and Mr. Greig, Craighead Park. In the collections of four varieties were nine competitors, the winning collection (Mr. Loudon's) consisting of Black Hamburgh, Muscat Hamburgh, Black Prince, and Trebbiano of admirable quality, and in all the collections were Grapes of great excellence.

The baskets of Grapes were not of the same high standard as the other classes, and not equal to those exhibited at the Alexandra Palace Show. The names of the prize-winners were given last week. Neither were the Black Hamburgs, as a class, equal to those which have been exhibited in the south, although the winners staged produce of high quality and of medium size. The season, however, is late for this variety, which explains the rather poor show. Muscat of Alexandria was exhibited in fine condition, the bunches being generally full and heavy, and the colour all that could be desired. There were eight competitors, the winning bunches (Mr. Johnson's) being perfect examples of 5 to 6 lbs. weight. Muscat Hamburgs were large and full, but, excepting the winners, were not perfectly coloured. The heaviest would weigh about 5 lbs. Madresfield Court was splendidly exhibited from the neighbourhood of Manchester. The best would weigh 5 to 6 lbs., and were remarkably well finished. In this class, however, were some moderate bunches. For size, appearance, and quality this is proving itself one of the best of Grapes for late summer and autumn use. Black Alicante was staged in grand style by eleven competitors; Mr. Hunter's bunches weighing 6 to 7 lbs., the noble berries being as black as jet. This was the finest class of the exhibition, the whole of the competitors staging worthy specimens. Mr. Curran secured the prize for "bloom" with this variety. In the class for Lady Downes' Seedling thirteen competed. The bunches were generally small, but the berries remarkably fine both in size and perfection of finish. Gros Colman from Mr. Upjohn, Worsley, had noble and well-coloured berries, but the bunches were not large; and Black Prince was exhibited in splendid condition by Mr. Stewart. On the whole, saving the Black Hamburgs, it was the finest and most remarkable exhibition of Grapes, perhaps, ever brought together, and, if we mistake not, the best examples did not come from the districts noted for a low rainfall—a rather suggestive circumstance.

The collections of fruit were, next to the Grapes, the most striking feature of the Exhibition. Mr. Johnston's splendid collection comprised excellent Smooth Cayenne and Queen Pines, and equally excellent Black Hamburgh, Royal Vineyard, Black Alicante, and Muscat Grapes. Very fine Conqueror of Europe and Lord Strathmore Melons; also Royal George and Walburton Admirable Peaches, and Pitmaston Orange and Murray Nectarines of superior quality, with good Plums, Apricots, and Figs. In the other two collections the Grapes and Pines were generally very superior, but the small fruits were somewhat deficient in merit. The classes for twelve and eight varieties respectively resulted in sixteen admirable collections. In these collections the Melons were very good, and the Peaches excellent; Nectarines, Plums, Apples, and Pears all of superior quality, and Gooseberries remarkably fine.

Pines were not numerous but very fine. Peaches were great in size, numbers, and quality, some splendid fruit coming from Ireland (Courtown House). Nectarines, as a class, were not equal to the Peaches, yet the successful dishes were very superior. Of the former, Noblesse and Royal George were the best, and of the latter Pitmaston Orange, Elruge, Victoria, and Violette Hative were the most noticeable. Plums, of which there were upwards of thirty dishes, were uniformly good, but not quite equal to the recent grand display at the Crystal Palace. Green Gage, Transparent Gage, Kirke's, Dove Bank, Victoria, Diamond, and Pond's Seedling were in excellent condition.

Apples and Pears were represented by numerous very fine dishes, but these were not equal to the high standard of the Crystal Palace and Alexandra Park Shows. Of Apples, the heaviest were Lord Suffield, Warner's King, Gloria Mundi, and Ecklinville Seedling; New Hawthornden, Tower of Glamis, Dumelow's Seedling, Cellini, and Peasegood's Nonsuch were also in admirable condition. Amongst dessert kinds, Irish Peach,

Oslin, Cox's Orange Pippin, Red and White Astrachan, Kerry Pippin, Cornish Gilliflower, and Court Pendu Plat were fairly well represented, but they were much inferior to the culinary kinds in point of merit. Of Pears there were some capital dishes, the heaviest being Doyenné Boussoch from Mr. Cairns, Coldstream, and Calebasse Grasse from Mr. Barrie. Mr. Ingram, Alnwick, had the premier prize for Beurré d'Amanlis, Beurré Diel, Josephine de Malinas, Marie Louise, Beurré Leon Leclerc, and Beurré Rance, of each excellent examples. Melons were generally handsome table fruit of high quality; indeed, it was the best show of Melons of the year. Gooseberries and Currants were remarkably fine and very numerous.

In the miscellaneous class was a very fine dish of the Parsley-leaved Bramble. Messrs. Stewart & Mein sent a new Melon, Sir Garnet Wolseley, beautifully netted; Mr. Turner, Slough, Cox's Orange Pippin Apples and very fine Doyenné Boussoch and Duchesse d'Angoulême Pears; and a very good collection of tropical fruits came from Mr. Leslie of Munches, Dalbeattie, comprising fruits of Passiflora quadrangularis, P. macrocarpa, and P. vitifolia beautifully mottled; Monstera deliciosa, and Guavas. With the fruit closes that section of the Show which is the most generally interesting—a Show which reflects the highest possible credit on managers and competitors.

Of the plants it may be said generally that they were the best ever exhibited in Edinburgh. They were, considering the lateness of the season, remarkably fresh and bright. The stove and greenhouse plants in the prize collections of Mr. Syme and Mr. Stewart were in admirable condition. The dinner-table Palms from Messrs. Thyne & Co., Glasgow, and Messrs. Methven and Sons were glossy and elegant, and included the first varieties of the day; the first-price plants for table decoration from Mr. Currie, Salisbury Green, were also in excellent order.

Ferns were exhibited in splendid condition, the *Todea superba* from Mr. Green, Canonmills Lodge; Mr. Paul, Gilmore Place; Mr. Currie, and Mr. Clarke, being especially striking; the fronds were 2 to 3 feet in length, and in perfect health and colour. *Adiantums* were admirably exhibited, *A. Cardicblossa* being 5 to 6 feet in diameter, and plants of *A. farleyense* were in the first order of health. Heaths were in capital order from Mr. Glass and other cultivators, and a pot of *Lilium auratum* from Mr. Lothian, Dalrymple Crescent, Grange, attracted much attention; it was in a 9-inch pot, had seven spikes and over a hundred flowers.

Conifers of all the most rare and elegant varieties were exhibited by Messrs. Methven & Sons. The Lawson Seed Company had an extensive collection of fine-foliage plants, large and small, new and rare; Messrs. Gordon & Son, Murrayfield, had grand *Dicksonias*; and Messrs. J. & R. Thyne noble *Palma*. Messrs. Veitch & Sons, Chelsea, had a rich and varied collection of the valuable plants for which that celebrated establishment is famed; and Mr. Williams brought out the gems of the Holloway emporium, and when he does that a treat of no ordinary kind is always afforded.

Floriata flowers were numerous and remarkably fine. *Gladioli* from Messrs. Robertson & Galloway, Mr. Codling and Mr. Fenning, Morpeth, and Mr. Campbell, Mr. Ross, and other exhibitors were simply splendid; and not less striking were the noble *Hollyhocks* from Mr. Kerr, Chapel; Mr. Parsons, Beechwood; and McFarlane, King's Meadows: at any rate here were no semblance of disease. *Dahlias* were not superior, the best coming from Messrs. Downie & Laird. Mr. McMillan, Broadmeadows, and Mr. Hugh Mason, Belfast, staged excellent boxes of *Roses*; and Messrs. Dickson & Sons, Waterloo Place, *Phloxes* of great merit.

Bouquets from Messrs. Drummond Brothers, 52, George Street, and Messrs. Downie & Laird were excellent examples of tasteful arrangement.

Vegetables were good in all the classes, the Leeks especially being remarkably fine. Most of the vegetables were fully too large for table purposes, size rather than quality appearing to have been the point aimed at. Cucumbers for Mr. Munro's prize for the Duke of Edinburgh were of all sizes and of more than one sort. Mr. Stewart, The Glen, was awarded the first prize for an excellent brace of small fruits. Altogether the Exhibition was a great and successful gathering together of garden products, with fewer immoderate examples of culture than is generally seen in displays of the same nature.

We cannot close this report without once more placing on record the frank hospitality and generous munificence of our Scottish friends. The heartiness of their welcome was singularly refreshing; and the energy and earnestness of their efforts, and the bond of sympathy which exists through all ranks, is a sufficient assurance that future gatherings will be as successful as has been the memorable Exhibition which we have attempted to describe.

The banquet in the Douglas Hotel, presided over by Ballie Methven, supported by Mr. Syme, Mr. W. Thomson, and Mr. McIntosh, was complete and enjoyable. The various speakers—the Messrs. Thomson, Mr. Dunn, Mr. Syme, &c., representing Scotland; Dr. Moore, Ireland; Messrs. Veitch, Williams, and

Turner, England; and Dr. Hogg the pomologists of Britain, received a perfect ovation. We left the beautiful city of the north with the impression that "they do not do these things better in France"—nor in England.

### NOVEL HORTICULTURAL SHOW.

A NOVELTY in floral and horticultural shows has taken place at Lancaster, when an exhibition by gaslight of plants, flowers, fruit, and vegetables was held in the Palatine Hall, and was most successful in every respect, the entries being extensive, the quality of the specimens good, and the attendance of visitors very large. The novelty of the exhibition, no doubt, tended to bring about this result, as this was the first gaslight-show ever held in Lancaster, and the experiment will probably be repeated another year. The scene in the Hall was of a most brilliant description. The principal successful competitors in the open class were—Mr. Jas. Ireland, Mr. Gill, Mr. Wm. Parker, Mr. R. Clapham, Mr. R. Dods, Mr. W. Rainford, and the Messrs. Hargreaves. In the amateurs' class—Mr. J. Stewardson, Mr. F. G. Dale, Mr. W. Parkinson, Mr. W. Johnson, Mr. R. Moser, and Mr. W. Jackson. In the cottagers' class—Mr. T. Richmond, Mr. J. Metcalf, Mr. L. Bennett, Mr. Geo. Normanton, and Mr. Geo. Winter.—*BETA.*

### CARNATIONS AND PICOTEEES.

It was a real treat to read Mr. Horner's notes. He gave us such information as can be obtained nowhere else about these fine old flowers.

It is plain from his remarks about the dates of flowering that we could not have a truly national show. In Essex our blooms are at their best just a month before his in Yorkshire. The third week in July answers best for London: about that time the Royal Horticultural Society's Great Show of Fruit and Zonal Pelargoniums is announced, let us hope that this class of old favourites will not be forgotten in the rage for new and more easily-grown flowers. My reason for writing is to ask from your correspondent the favour of answers to the following questions:—First, a Carnation Show is announced at the Botanical Gardens, Manchester, September 15th and 14th, is it possible that a show can be held at that time? and how are the blooms obtained? Second, could Mr. Horner give a list of the best Carnations and Picotees for exhibition purposes? I quite agree with the remarks on dressing the flowers; there is fair and legitimate dressing which every exhibitor of cut flowers of whatever sort must understand, or he is not likely to be successful. Dressing that goes to the extent of "deceiving the public" is not legitimate, but I do not think it is often attempted. I well remember showing my first stands of twenty-four and twelve cut blooms of Chrysanthemums. I had touched the flowers up a little and had removed a few bad petals from some of them. On arriving at the room where the exhibition was held I showed the stands to a friend who had been long at the business. His remark was this—"You have splendid blooms, but they must be dressed. If you like I will pull them up for you." He did so, and on that occasion I think I stood highest on the list in both classes. Now, like Carnations, some of the varieties needed no artificial aid, others had the centres pulled quite out and the flowers pulled together with blocks; but no additions must be made to the flowers. If a flower has not a centre, one must not be put in. I presume that the flowers exhibited at the National are upon cards, as at the London shows.—*J. DOUGLAS.*

### GRAPES AT THE EDINBURGH SHOW.

THE following are facts concerning the respective weights of the first and second heaviest bunches of White Grapes. The first prize was awarded to J. Curror, Eskbank, whose bunch was said to weigh 26 lbs. 4 ozs., and when weighed in the show room it weighed 26 lbs.  $\frac{1}{2}$  oz.; while the second prize was awarded to myself, the Judges saying that my bunch weighed 25 lbs. 15 ozs. Prior to starting for Edinburgh my bunch weighed 26 lbs. 8 ozs., which can be attested by two witnesses. Not being allowed to be present at the weighing, I requested the bunches to be reweighed, but this was refused more than once within the two days. This seems a very strange procedure, and I leave the public to judge from these facts.

I object also to the first-prize Grapes being one bunch, as from what I saw myself it was two bunches, and I am backed in this by six of the best Grape-growers and principal prize-takers at the Show. I have had bunches of the same sort

over and over again, and I have always cut those parts away to prevent people saying it was more than one bunch. I should like to hear the opinion of two or three able men and parties that are not interested in either of the bunches mentioned. It surely ought to be known what constitutes one single bunch of Grapes.—*JAMES DICKSON, Arkleton, Langholm, N.B.*

### TAKING UP GLADIOLUS.

It is not often that I differ from so experienced a cultivator as Mr. Douglas, but I am compelled to do so as to his advice in last week's Journal about Gladiolus. He says, "In a large collection there are always a number of plants of which the stalks die off prematurely. The best way is to pull them up and tie them in bundles to burn. Some of the best growers consider this to be a disease, but it is probably nothing but degeneration, as no trace of disease is apparent in the corms." This degeneration in a previous sentence he explains to be the result of delicate constitution and of their cultivation in England.

Now for my reply. I send you herewith a root of *Celemene* which I imported this year from France. You will see the old corm has thrown up two shoots and formed two new corms, and you will perceive that they are fearfully diseased. Will you kindly look at them and then forward them to Mr. Douglas? The stalk has prematurely decayed, but the corms are diseased, and being newly imported bulbs it is not owing to their cultivation in England. I have observed the same premature dying-off in a seedling bed where degeneration cannot be laid to their charge. I do not like, if the bulbs are of a good sort, to burn them without close examination; and I am confirmed in this by a curious experience of last year. I took up some corms of *Madame Desportes*, a variety which it seems impossible to keep free from disease. At planting time they looked so scrubby and bad that I determined not to put them in my best beds, but planted them with some others in my kitchen garden. Strange to say they started into growth, and I have had some capital blooms from them. I therefore take up the bulbs when a plant dies off prematurely and examine the corms well. If they are badly diseased I destroy them; if only speckled I keep them on, hoping to secure perhaps some of them for next year.—*D., Deal.*

[This is a subject that "*D., Deal*," and I must agree to differ upon. He believes that the Gladiolus does not degenerate under cultivation in England. I believe that it does, and at a very rapid rate too. If your correspondent will discontinue importing for three seasons I believe he will hold the same opinion. The specimens sent are diseased and would never recover; those alluded to in the "*Doings*" were quite different. The bulbs were apparently sound, but they will never throw strong spikes again. They are afflicted with what might be called "the yellows." Many growers complain of the same. The late Mr. Standish told me that my bulbs would soon degenerate, and that I should have to give up their cultivation after a time; but I keep up a healthy stock from seed and by occasional importations. I may say that I have had bulbs die in the same way as the specimen sent, and amongst newly imported roots too. They might be from disease; degeneration is a different thing.—*J. DOUGLAS.*]

### BOURNEMOUTH, ITS SOENERY AND VEGETATION.—No. 1.

To the ordinary traveller who makes London his centre a journey by the South-Western Rail to Southampton, and beyond that place, presents larger tracts of waste unprofitable land than is to be met with on any other line that I am acquainted with in England. Certainly some of the Scotch railways pass through districts more truly wild, and consequently having a more picturesque appearance; but the waste land met with on the South-Western line from London has but little that is inviting about it, especially the portion that almost approaches the suburbs of the great metropolis. Though far from being sterile its vegetation is not luxuriant, and it is generally either flat or the undulations look tame, and, unless seen at the best period of the year, present but little that is cheering beyond the atmosphere which is no doubt exempt from the London impurities; but after passing the grief-stricken shadow of Woking a little more cheerfulness is infused into the landscape. Dry chalky hills show diligent cultivation, and trees and hedges look flourishing even if the grass land be burnt

up, which it is likely to be in dry seasons. Still prettier country is met with at Basingstoke, while the Ivy-clad ruins of a religious edifice close to the station attract the eye of the railway passenger on emerging from the station. The ancient town, or rather I should say city of Winchester, is surrounded by villas and residences vying with each other in taste and most likely comfort, suggestive enough of the peaceable times we now live in as compared with those in which Saxon and Dane fiercely contended for supremacy, very likely on the spot now so highly ornamented.

Journeying farther to the south, and passing through a district not remarkable in any way beyond the fact of seeing a sheet or two of water where least expected, we are at length brought up to a stand at one of the outskirts of Southampton, and water in great abundance is before us. The first view would almost make it appear as if it were a lake, for it appears to be surrounded by land; but a closer acquaintance dispels the idea, and the peculiarities of the vegetation on its shores attest at once its connection with the ocean. Neither is it at all inviting just at that point. The low muddy shore contrasts unfavourably with some sheets of inland water where a bolder coast line exists. But we have little time to take notes, and with the whistle of the engine we are off again farther south, but skirting this water as we go for some distance, and when we leave it we are presently brought into contact with extensive tracts of woodland or rather cultivated land profusely wooded, which, extending some distance, gradually brings us into that tract of country which the schoolboy and historian is more likely to regard with more importance than the traveller who passes through it. The New Forest, in fact, being perhaps the very oldest object to which the term "new" is still applied, for we are told it is fast approaching eight hundred years since it was so designated; but the term now seems more becoming, perhaps, than it was some centuries ago, as large portions of it have been newly planted, but to the unlettered traveller there is but little to see from the windows of a railway carriage that is at all interesting. Certainly the quantity of timber fit for ship-building purposes is very small indeed, while much that has recently been planted is Scotch Fir, large breadths being met with that appear to have been planted at various times, and is more or less thriving according to soil and situation, the former not always good—in fact I should say much of it only indifferent. But it would appear that some years back excellent roads had been formed, which being generally in straight lines and of great length must be of great service in traversing so wide a tract. Heathy wastes often occur with a few stunted Scotch Firs, but comparatively few Hollies or Birehes; and I do not remember noticing any Yews or Junipers, but doubtless they exist there, while the marshy spots present the usual herbage found in such places, with Alder, Willow, &c.; and probably the plant the ordinary traveller sees most abundant all over the place is the common Brake, which is met with almost everywhere, often contending with the Heath for the possession of those waste places which more robust vegetation refuses to occupy.

Passing over the remaining intervening space we reach our destination. Bournemouth, like many other fashionable watering places, owes its importance to its dry and healthful situation in addition to its excellent sea-bathing qualification. Bold sandy cliffs of great height have been washed into nearly a perpendicular condition, with sufficient sandy or gravelly beach at their base, free and safe to loungers in all conditions of the tide, excepting perhaps in extraordinary storms; and with a shore extending for some miles in this way is duly made use of by those who make a sojourn by the ocean a feature in life. The high cliff forming the coast is broken for a short distance by the narrow valley of the Bourne, a stream of no greater size than what a full-grown schoolboy would regard as only a good jump. It, however, has been turned to useful account, as will be shown hereafter, in aiding the embellishment of the place; and as it necessarily runs through the valley we may say that what may be called the business part of the town is mostly concentrated in or near the sides of the valley, while the residences of those who seek health and relaxation are mostly placed on the high table land on each side; and differing from most other places of a like kind, there are rarely two dwellings found united together, each occupying a site by itself, and in most cases I should guess from one to two acres is attached to each dwelling, the greater portion of that area being of course ornamental ground in the shape of shrubbery, lawn, and flower beds. Furthermore, it is only fair to observe that the ground originally appears to

have been a Scotch Fir plantation with an undergrowth of Heath, Brakes, &c. And as Bournemouth is the creation of the last quarter of a century or so, the design for its dwellings has been laid out with due care and attention to future effect—long straight roads wide enough for all purposes, with spacious footpaths on each side, the boundaries of which are sometimes Holly or other fancy evergreen hedges, or it may be ornamental iron railing. The dwellings, standing back all about equal distances from the road and 100 feet or more from it, give room for the closely shaved lawn, on the margins of which a sufficiency of Scotch Fir trees has been retained when the building was put up, and shrubs of suitable kinds introduced amongst them, with not more flower beds than seem needed for the due embellishment of the whole. Neatly kept carriage and back entrances of course are provided, while the residences themselves, being all of modern creation, are no doubt well designed for the families they contain. It is almost needless to say that architectural skill has been duly exercised in varying the designs, and endless are the diversities of form which two or three different colours in bricks and blue slates can be made to assume.

Such is Bournemouth, the winter residence of many who occupy an exalted position in the land, while to the casual wayfarer the accommodation for a night or two is not so good as that of many other places, and the roads leading to it do not pass many villages where the benighted traveller may take shelter. True the decayed old towns of Poole on the one side and Christchurch on the other are not far away, and act as landmarks to their fashionable neighbour rising about midway between them, and from Bournemouth the Poole road and Christchurch roads are important avenues, the latter in more sense than one, as the trees lining it overshadow the footpath, and render it very pleasant in the hot dry weather of the dog days; but enough has been said of the general features of the place. Let us now turn to the horticultural side of the case and see in what way the site is made to suit the various products generally required to constitute the ornamental; and although the place is still young in the sense in which towns are generally regarded, it is old enough, and there have been experiments enough to prove what class of plants seem to thrive best on the spot; and as it often happens that there is a something or other patronised more extensively in each place than in others, it may be said that Bournemouth seems more cosmopolitan in this way than many other places, and the anxiety which each may have to outdo his neighbours in variety has doubtless led to many things being tried that have been found not to answer; but on the whole shrubs of most kinds are sure to do well, and I need hardly say that a great preponderance seems given to evergreens, while deciduous shrubs are more scarce, but a few passing notes on such as do well will not be amiss here.

We have said that the general characteristic of the neighbourhood is sand, but sparingly intermixed with gravel, for even the seashore is not wholly covered with shingle, although cliffs from 100 to 200 feet high are washed down to produce the gravel. Sand of a pale yellow seems to have produced an herbage forming the thin tufty particles of peat on which the common Heaths grow with more or less vigour, and Scotch Firs when planted grow also, but not fast, and I do not hear much of their self-sowing and reproducing themselves as they often do in kindred situations.—J. ROBSON.

#### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*DRABA MAWII.* *Nat. ord., Cruciferae. Linn., Tetradynamia.*—"A native of Panchorbo in Old Castile, between Burgos and Miranda, where it was discovered by Mr. Maw in 1870, and introduced into his garden at Broseley and into the Royal Gardens of Kew. It flowered in the spring of 1873, and the fruit ripened for the first time in May, 1874. It is an excellent rock plant, of compact habits, bright green foliage, and red-brown buds, that are succeeded by crowded pearly flowers."—(*Bot. Mag.*, t. 6186.)

*CROCUS BORYI.* *Nat. ord., Iridaceae. Linn., Triandria Monogynia.*—"This pretty autumn-flowering *Crocus* is common in many of the islands, and on the mainland of Greece. We have specimens at Kew from Corfu and Cephalonia, and from Mount Parnes and Mount Corydalis, in Attica. It was first brought into notice by the celebrated traveller and naturalist, Colonel Bory de Saint-Vincent, after whom it was named by his friend Gay in 1882. He speaks of it as covering the mountains after the rainy season, from November to

January, flowering with the *Mandragora*. There are several closely-allied Grecian forms, as *O. laevigatus*, *Tournefortii*, and *Orphanidia*, of which we can scarcely judge whether they are species or varieties till they are watched side by side under cultivation. This one is characterised by its pure white unstriped flower with a yellow throat, and it is one of the few *Crocuses* that have white anthers."—(*Ibid.*, t. 6187.)

**WAHLBERGIA KITABELII.** *Nat. ord., Campanulaceae. Linn., Pentandria Monogynia.*—Flowers purple. "W. Kitabelii is a native of the Alps of Croatia, Transylvania, and the Banat, whence it was introduced by Messrs. Backhouse, who sent flowering specimens from York in May of the present year."—(*Ibid.*, t. 6188.)

**CHERRIES.**—"Two very fine and comparatively little known varieties of Cherry, belonging to the group of the *Geans*, from Messrs. Rivers & Son of Sawbridgeworth; ripe early in July.

"The *Early Lyons*, *Rose Hâtive de Lyons*, or *Guigne Hâtive de Lyons*, is a very large and handsome Cherry, which besides being excellent in quality has a very grand appearance for exhibition purposes. The fruit is roundish heart-shaped, with a faint depression or suture on the flattened side, and having the stalk, which is  $1\frac{1}{2}$  inch long, set in a rather shallow cavity. The skin is blackish crimson-purple, or glossy blackish mahogany colour. The flesh is of a very dark brownish-red, sweet, tender, juicy, and well-flavoured. It is an early variety, ripening naturally about the end of June.

"The *Ohio Beauty* is of a different character, belonging to the group in which the flesh is pale and the juice uncoloured. The fruit is large, roundish heart-shaped, with a faint suture. The skin is yellow, spread over with bright rich red on the sunny side. The flesh is pale yellow, tender, sweet, and juicy. It ripens about the same time as the *Early Lyons*.

"Both varieties are worth a place in every garden where Cherries are prized."—(*Florist and Pomologist*, 3 s., viii., 193.)

### ROSES ON THEIR OWN ROOTS.

In answer to a query with regard to Roses on their own roots, which I recommended, and which "*Cornubia*" thinks not likely to be generally successful, I have not had very much experience of my own lately, but some of my oldest-established plants, as of *Gloire de Dijon*, *Général Jacqueminot*, &c., are on their own roots, and do not seem inclined to wear out; and I know the late Mr. Perry used to succeed admirably with Roses on their own roots, encouraged to grow freely and pegged-down. I know it would not answer for many of the weaker kinds, but any of the stronger Hybrid Perpetuals would answer well with this treatment; indeed, one cause of the success of the *Manetti* as a stock is the fact that the Rose is buried below the union of the scion and stock, and the Rose tree soon becomes established on its own roots as well as having those of its foster parent to depend on. By parity of reasoning the cause why a Rose budded on the Briar has so often an ephemeral existence is that it only has the roots of the Briar to depend on, which too often is a broken reed—a mere hard lump, only fit to make into a pipe-head. Some Roses on the *Manetti* and some on Briars in a northern garden the other day, 600 feet above the level of the sea, made me more than ever an advocate for the *Manetti*, or perhaps made me more decidedly condemn the Briar. Only a few days ago a lady took me to see a *Maréchal Niel* growing against a south wall, to show it me and ask me why it did not go on doing as well as it did the first two years. The reason was too apparent; it was budded on a standard Briar, and the stock was hard and hidebound, and could not supply sap enough for the head, which had been vigorous, but was now dwindling. On the *Manetti* I have seen a *Maréchal Niel* make a stem  $5\frac{1}{2}$  inches in circumference in as many years.—C. P. P.

### HYBRID GRAPES.

It was stated in the *Journal* a month or two ago that the Marquis of Bute was planting a piece of ground on his Cardiff estate with Vines selected by his gardener in France, with the intention of putting the practicability of the open-air culture of Grapes to fair proof, &c. Would not a similar trial in Wales or the south of England of some or all of the varieties obtained in this country by crossing the foreign Grape (*Vinifera*) with the wild species of this country be worth the effort? Hybrids thus obtained are more healthy and hardy in vine, and ripen their fruit earlier than the foreign parent; and although the fruit may not equal that of the *Vinifera* in superior luscious-

ness for the table, it yet has a briakness and relish very palatable after dinner, and some are worth growing under glass. I have been experimenting in this way many years, have raised thousands of such seedlings from more than eighty different crosses, and have kept a record of every cross and every individual plant. To enable you to judge of the effect of this process on the quality of the fruit I will endeavour when it ripens, about October 1st, to get a cluster of a few kinds to you.

The varieties of the *Vinifera* will not succeed in any part of this country. They have been often and thoroughly tried, and have uniformly failed. They will not bear our winters in the northern section, and the mildew destroys them in every part of the country, even where the summer is warm and long enough to ripen the fruit.

The American Vines used in these experiments were of two species, as they are called, found growing wild in this vicinity. I do not think we have more than two species in this country, if indeed we have more than one. The *Labrusca*, *Vulpina*, and *Riparia* are clearly all one and the same species. They are found growing wild in swamps in freshwater meadows and on the banks of sluggish streams—localities where their roots are always in wet soil, and are submerged in many instances during the whole winter without injury. They are very rarely found on dry upland, and when placed there they do not thrive so well as in their native habitat. The fruit is large, varies much in colour from a light green to jet black; most varieties have a bloom, some have a strong musky odour, and others none of it. Some are comparatively tender and good, but most of them have a hard sour pulp enclosing the seed. They all have a pleasant but pungent juice between the skin and pulp.

The other species or variety is found only upon high ground. The fruit has no odour, is always black with more or less bloom, below medium size, of early maturity, with tender flesh and very acid and red juice. There is no constancy in the form of the foliage of either kind. The swamp variety generally has down on the under side of the leaf, and the hill variety is generally without it. There is, however, one characteristic common to both kinds: half, or more, of each kind found growing wild or raised from seed have infertile flowers with no pistillate organs. Other Vines of each kind have pistillate organs, but with stamens defective, short, and curved backwards, so that the anther is near the base of the pistil, and other Vines of both kinds have perfect flowers. Hybrids raised from this stock bear our coldest winters safely, and are affected but little, and some of them not at all, by mildew; and it seems probable that the American parent would impart the qualities necessary for a healthy growth in England.—GEORGE HASKELL, *Ipswich, Massachusetts, U.S.*

### THE STATUE GARDEN AT BELVOIR CASTLE.

THE statue garden is connected with the flower and pleasure gardens which are within the enclosed grounds that encompass the Castle. It is situated on the lower slope of the eminence on which the Castle is built, and is encompassed by forest trees, amongst which three noble examples of Silver Fir are conspicuous.

This garden has the effect of a framed picture looking through the arched opening that commands it from the path that runs along the edge of the steep grassy slope that sweeps down and surrounds the clustered flower beds that fill the lower part of the hill side.

A central bed and four subordinate vases mark the position of a large circular and four concentric beds. The four principal beds require one thousand large *Geraniums* to fill them.

Disposed about this garden are life-size statues of the presiding mythological gods and goddesses, sculptured by the father of Colley Cibber, the dramatic author. He was Caius Gabriel Cibber, a native of Holstein, living in England during the reign of Charles II. His most celebrated statues are the figures at Bedlam of Melancholy and Raving Madness. Most of the statues of the kings at the old Royal Exchange, many figures at Chatsworth House, and that of William of Wickham at Winchester College, are only a small number of his many other works. Juno rises dignifiedly over all; Diana with her hound; Flora wreathing flowers; Ceres scattering the rich gifts of corn; Pomona distributing her fruit; and Bacchus pressing the purple juice from the clustered bunches he holds.

Surrounded by lofty trees it is only in very dry seasons that a good display of flowers can be secured, shade and moisture

Fig. 64.—THE STATUE GARDEN, BELVOIR CASTLE.

inducing growth rather than blossom. Better effect can be secured in early spring, when hardy shrubs and bulbs make a charming display.

### PRUNING AND TRAINING FRUIT TREES.

SURELY many are too inclined to lay down general laws: one man advocates over-pruning, another hates the sight of a knife or a pair of scissors. There is no such thing as a golden rule, yet different soils and different climates make a corresponding difference in every kind of fruit. Then, again, while one kind of Apple or Pear will come into bearing earlier if pruned but little, another may be brought into bearing early by close pruning. Once get a fruit tree into good bearing, and let it bear one heavy crop, it needs very little pruning to make it bear afterwards. Then, again, nearly all fruit trees may be spurred, only if you try to obtain spurs on Peaches and Nectarines it must be done merely by pinching out the growing tops of young shoots. I quite agree with Mr. Luckhurst; so long as one can produce a healthy tree and good fruit, it does not matter a bit what the shape is or how it was trained. At all events, in the case of bush fruits or pyramids of Pears, Apples, and Plums, I care very little as to the shape, but merely cut as each tree may require it. In some gardens with wet subsoils root-pruning may be a necessity: with me it would be an abomination, except under very exceptional circumstances.

"W." in his interesting account of Cleveland House and Mr. Legge's general success, speaks of the fear of fungus in Vine borders from cutting away Vines and leaving the roots in. I believe fungus to be an easily-averted danger, and will never arise where Vine borders are kept sufficiently moist, and a little watering with liquid manure with diluted superphosphate will soon check it.

—Can anyone tell me how Gansel's Bergamot Pear is doing with them as standards or pyramids? I find the flavour much better and less gritty at the core than off a wall; and it is bearing very well on one young tree with me, and on another older tree it always has the peculiarity of never setting more than one fruit on a bunch.

My Seckles must this year have set nearly every flower. I have not thinned them, and they are growing eight to ten in a bunch, and on short-spurred branches where the flower buds were near together, they are clustered like Grapes, from twenty to thirty in a cluster. My crops of Marie Louise and Van Mons Leon le Clerc on two largish bush standards are laden from top to bottom, the branches bending down and overlapping. They ought, of course, to have been thinned, but large trees take too much time to have their crops properly thinned, and so they have had to take their chance, and I do not find that thinning bush standards much increases the size of the fruit.—C. P. P.

### ENVIRONS OF LONDON.

SUFFICIENT scope is afforded in this wide compass for a few remarks on ornamental gardening. The country seats of the nobility and gentry are centres of attraction to all. They are proud heirlooms of their respective families, and are, furthermore, spots which the great mass of the people cherish. By no class are the gardens of the great more highly esteemed than by the Londoner. For one day spent in these highly embellished enclosures he will prepare for half a year, and when the visit has been paid he enjoys a retrospective feast until it recurs. An old church, the blue sea, and a beautiful garden are magnet points of interest to the inhabitants of Britain generally and to the citizens of the metropolis particularly.

Another trait in the character of the Britisher is that what he likes to see he also likes to read about. How else could the literature of gardening be patronised to the extent that it is? Not only every great gardener but every little one must have his paper; and beyond all these, thousands who have no gardens delight to fancy they have a share in the craft by conning the current gardening lore which is weak by week provided. I am one of these. I am a citizen and have no garden—at least I dare not call it one in the columns of our Journal; yet I scan its pages weekly, and in fancy—only in fancy—seem to luxuriate in fruit and revel amid flowers. Still, if that fancy affords enjoyment what matters its substance or non-substance? I enjoy it and that suffices, and I believe—nay, I am sure—that I benefit by it, and therefore my enjoyment is after all something more than a vapid dream.

The Irishman, in one sense, was right who, after walking through Chatsworth Gardens, observed, "I am better off than the Duke: I enjoy them and he pays for them."

I am one who believes that such literature as the Journal, which I delight in, has not only done much for gardening and gardeners, but has contributed to the greater enjoyment of many homes by making these homes more attractive by investing them with charms of refining influence. Especially is this so in the adornment of suburban homes of every class. This literature (with the teachings of the public parks) has done wonders in stimulating a taste for gardening pursuits, also for perfecting that taste. The fruits of it are seen on every hand. Not only have great gardens by it achieved greater fame, but small gardens have been made models of attraction, and barren squares have been converted into plateaus of beauty.

In few things is the change greater (and that change improvement), than in the surroundings of the villa residences of the metropolitan environs, and of other business centres, during the past twenty years. Where, mayhap, was a Privet hedge, a Lilac bush, and a patch of weedy gravel, now are elegant vases, smooth lawns, striking Conifers, and bright flowers. The attractive force and high keeping of the little frontages of villa residences are amongst the most pleasing feature of the day. The management of these enclosures, and the taste displayed in their arrangement, is in the highest degree creditable to amateur effort.

I am led into these thoughts by an afternoon's airing. I wanted to revel in the fresh breeze. I thought of the sea, the forest, green fields, and flowers. The sea was out of the question, for I must be at my "breathings" in half an hour. The parks! No; I had been there so often. They are beautiful and I shall go again, but I desired something more novel and less formal. I wished to ruralise, and to do it quickly. "Go to Lee station" divined a genial spirit, "and from thence to Lee church and then anywhere." It was enough, being a new idea, and I followed it up as fast as limbs and train could take me. Emerging from the London Bridge station, flying literally over the housetops, the view was a dispiriting expanse of miles of chimneys and a canopy of smoke. By-and-by comes a change, but not much like the country I longed for, yet in fifteen minutes the fields burst in sight—soft hills of verdure, and the fragrant hay! That is the country almost within the precincts of the city, and I am shortly at my rendezvous—Lee church.

The old edifice is being restored. This is an age of church restoration, and is one of the happiest signs of the times. It denotes not only that the long past is cherished, and that the works of our ancestors are recognised, but that the still longer future shall have preserved to it a typical impress. Besides the memorials, the churchyard contains Weeping Willows, sorrowful by their drooping yet cheerful by their living green; Cypress and Cedars. But it is on the surroundings, of which the fine structure is the centre, that I would give a passing glance. The site is elevated and breezy, and elevated on the elevation are magnificent trees. The roads converging to this vantage point are veritable borders of foliage, and behind this green fringe are detached and semi-detached villas with frontages containing charming examples of miniature gardening. The very names are suggestive of the nature of the locality. Prominent is The Cedars, the fine place of Mr. Penn with its majestic Elms, its Ivy-capped wall, and fringe of Conifers. Even the outside view is imposing, for it is clear that the trees and grounds are well cared for and tended. Then there is "The Elms," "The Limes," "The Hollies," "The Lilies," and even "The Briers," with a multitude of "cottages" with tree or rural prefixes or affixes.

Many of these frontages are most attractive, and the owners would seem to vie with each other in good taste and good keeping. In one we find choice Hollies dotted over a faultless lawn, in another a stately Araucaria and cheerful lines of Pelargoniums and Lobelias; in a third is an elegant Deodar sweeping the ground with its graceful sprays. Then we find terraces, and vases, and window-boxes, and Ferns, and rockeries. These are examples which continually recur in what are not hard cold streets, but bowery promenades, for each garden has its fringe of overhanging trees.

The favourite trees are the Acacias. The compact yet elegant outline of these trees specially recommend them for fringes in villa gardens. For this purpose they should never be omitted. The Ailanthus (Tree of Heaven), is also employed, and its dignified grace renders it most appropriate. The Variegated Maple is often dotted in, and if in proximity to a small Purple

Beech its purity of colour is heightened. We find amongst Conifers, too, the Wellingtonia, the Cypress, and the Thuja aurea. We note walls draped with Roses, and Jasmines, and Clematis, and, above all, we find neatness and order, which betoken the owners' love for these gardens. It is this love and consequent care which brings out a garden's beauties and makes it a teacher and a gladdener—not to the owner only, but to passers-by. The charms of a garden consist not in its size but in its keeping, and those of "large views" may well take a lesson from the trim and faultless plots of many suburban homes.

But where am I? Actually thus cheerfully scribbling in my dingy office. I could not have been in this happy vein but for my afternoon's airing. Such is the influence of gardens not one's own. Those who possess them mayhap do not always recognise the good they do in fringing the suburban pathways with trees and flowers which cheer the hearts of hundreds. I am now ready for business again, and am the better for my visit and my pleasurable attempt at describing it.—A CITY MAN.

### STRAWBERRY CULTURE.

YOUR correspondent at pages 182 and 242 has made some observations, to which I think so many exceptions may be taken that I am induced to pen a few lines, in the hope that those of greater experience may give the readers of "our Journal" their opinion for the benefit of all interested.

We have certainly had an exceptional year for quantity, though the rain has very much injured the quality of the fruit; but the produce of 67 lbs. on sixty plants planted last September, grown in very light soil after Potatoes (a crop not heavily manured in general), without any manure added at the time of planting, and twice transplanted, is beyond my comprehension. My objections to the mode of cultivation recommended are, twice transplanting; deferring the final planting till September; planting without manure; planting after Potatoes; taking the runners from each alternate row; and continuing the plantation after a heavy crop.

I think the young plants should be removed to their fruiting quarters and allowed to make all possible growth there, for which purpose they should be moved as soon as they have made sufficient roots for their support; that the ground should be heavily manured and consolidated by roller or rammer before planting, and then mulched to enable the plant to become strong before the frost sets in; that Potato ground is objectionable from the annoyance caused by young Potatoes sending their shoots up; that it would be more in accordance with horticultural practice to take the runners from every alternate plant (which are proposed to be cut out) than from every alternate row, every other plant of which must be weakened by taking four to six runners from it; and finally, that when a plant has brought to perfection 1 lb. of fruit—if such can be produced on one-year-old plants—it would be more economical to destroy than continue the cultivation.

I will very shortly state my mode of cultivation, which has been very successful on plants two years old. I grow large crops and then destroy them. If they fail to bear a crop the second year I keep them the third year, but never beyond. I grow them where Cabbages have been, and for which I manure heavily. I do not cut spring Cabbages, but pull them up, and at the same time water the hole with ammonia water, which brings forth the slugs. This leaves my ground free by the time the runners are ready to plant out, and I prepare the ground for them by taking out as much as the spade lifts from a trench 1 foot wide and wheeling it away, bringing back a compost of three-fourths heavy loam, one-quarter manure, consisting of pig and cow manure in equal proportions. This I have rolled or rammed down 1 foot wide and 3 or 4 inches above the level of the soil. These flattened ridges are 2 feet from centre to centre, and made as solid as possible; I then have holes made with the dibble 2 feet apart and 5 or 6 inches deep and filled with liquid manure. My runners are rooted in the same compost rammed into gutter tiles 4 inches wide and a foot long in which two or three are rooted, and when sufficiently strong are removed to their fruiting quarters. A puddle is made so that the young plant when pressed down stands just clear of the ground, a Seakale pot is put over each (without the cover), for a few days and the ground mulched till the middle of October, when it is removed and dug-in to the quarters for Cabbages. Just before November I cover all the ground with dry leaves with something thrown on to keep them from blowing away. This is removed in the spring, the

ground well watered with lime water, dressed with soot, and mulched at once with long manure, which the rains render clean before the harvest is reaped, and I have never failed to secure one.—AN OLD SUBSCRIBER.

### CHAPTERS ON INSECTS FOR GARDENERS.

No. 8.

I MUST own that I have sometimes felt a malicious satisfaction in acquainting persons who have twitted me with a liking for insects, and who had a partiality for crabs, lobsters, or shrimps, that they were given to devouring creatures which were once actually classed with insects, and which are beyond all doubt near kin to spiders and woodlice. We must clear our ground as we go, and therefore I at once put aside all the regiments of spiders, mites, woodlice, &c. Numerous and oftentimes annoying as they are in gardens, they are not properly insects, and therefore I, as an entomologist, am not bound to give account of their proceedings. So far it is well that I am not answerable for their manœuvres, since on the whole they are more injurious than beneficial. The Arachnids, now forming a separate class in science, of course come nearer to insects than our aquatic friends that are so freely devoured and all their brotherhood, some of microscopic smallness. But the legs are eight in the spiders, the head and thorax are continuous, and there are successive moults, but no true metamorphosis exists. These characters, without going further, are to me conclusive as to the separation now agreed upon by most naturalists, though one whose name must certainly be ranked high in our annals upholds the theory that the class Insecta should comprehend all these eccentric individuals. About the large tribe of the Acari, I merely venture the remark here that we are only just beginning to discover the influence they exert throughout nature, and especially amongst vegetation. And to me one of the most peculiar circumstances in the history of these mites or ticks is the fact that many species can live indifferently on animal or vegetable substances. Often butterflies and moths are taken at large attached to the wings or thorax of which are a number of these small fry, sometimes operating so successfully as to exhaust the insect and render it incapable of flight. It would be going too far to assert that the Acari have in all cases been obtained from flowers that the insects have been visiting, yet it is certainly the fact that they do transfer themselves from flower to insect, and, perhaps, *vice versa*. I have never heard it suggested that these mites when young prefer vegetable food and when older prefer an animal diet, but the hypothesis may be started. The evidence at present is rather against it. For example, I have repeatedly found that one species of tick which infests cage birds is conveyed to them, sometimes, with the seeds supplied as food. Amongst these seeds, however, I have found Acari, both full grown and very small. The injury Acari or mites do to flowers is of no great consequence ordinarily, but some species "ply their vocation" in a manner very objectionable to the horticulturist. They visit his seed-drawers and parcels, and owing to their rapid multiplication, and the difficulty there is of detecting them amongst some seeds, they may occasion much disappointment as well as money loss.

To proceed: I must here also caution-off the Myriapoda, they have no claim upon my attention. A series of developments they may pass through in the majority of species, but there is nothing approximating to the transformations of insects. The head is distinct, not so the thorax and abdomen as in true insects. With the Myriapoda the two form one continuous body, remarkable also for the number of legs attached to it, and thereby again separated from the class Insecta. It is rather ludicrous to read in one author that these creatures are to be divided into two sections, the "Hundred-legs" and the "Thousand-legs," and he immediately proceeds to show that both names are incorrect. We find neither the hundred, nor the thousand legs, the difference being mainly this, that in the first each segment has one pair of legs, and in the second two. The Scolopendra electrica, or electric centipede of our gardens, is a familiar example of the moderately-legged group, a creature decidedly of ferocious habit, and feeding by choice on small insects and other living things. Another resident in most gardens represents the Thousand-legs—viz., *Julus terrestris*, popularly called Maggy-many-feet, at least this is the name applied to it in some English counties. It has not a thousand legs, yet several hundreds might be reckoned up; and though it occasionally devours the rootlets of plants, this Myriapod subsists largely on decaying vegetable sub-

stances, and is therefore hardly to be classed with our unquestionable foes.

Leaving these I must make passing mention of the mysterious tribes of minute creatures classed under the title of Thysanuridae, which have also received the English appellation of the "Spring-tails;" incorrect as it appears, all these are not furnished with tails, and therefore they cannot spring with them or wag them. By the way, friendly reader, do not confuse these with the Thysanoptera, not so unlike in size, but true insects, though of peculiar habit, about which I shall have more to say. An unfortunate race of beings these; no one wishes to own them. Entomologists stand at the door of their class and cry "No admittance," for the Thysanuridae, though six-legged, have differences of structure which separate them from the insects, though a few eccentric individuals have considered that these diminutive creatures had a likeness to the larvae of Neuroptera, only they never get beyond larvahood. In vain have others tried to connect them with the Acari or the Myriapoda, and they remain a square group that we cannot fit into any of our round holes; somewhere between the mites and the insects proper may be probably their position at last. "If they're not insects they did ought to be," remarked a gardener to whom some were shown, not meaning by that a compliment, as "insect" with him was synonymous with whatever was unpleasant and troublesome. Sundry species have been called "Scale Insects"—an ill-chosen name in both its halves, since there are other scale insects, yet it is so far correct as to the external aspect of the Thysanuridae, since they are scaly. As an illustration I do not know that I can select a better one than *Lepisma saccharina*, a creature visible to the unassisted eye, and not a stranger to careful housekeepers and cooks, who detect its sneaking ways. To this the vernacular name of "Fish Scale" has been given from its slippery body, and though specimens of it generally reside in cupboards and odd corners in the basements of our houses, the Fish-scale also visits upper rooms, and in libraries, especially where the walls are damp, it makes sad havoc amongst books and manuscripts. From drawers, too, containing loose papers thousands of these little pests have been shaken out. Some Thysanuridae are terrestrial in habit, living in loose earth, or else spending their brief existence in running over the surface of the ground. Mr. McIntire, in his admirable sketch of the history of the group, notes with regard to the genus *Sminthurus* as follows:—"I once saw when a friend was potting-out some Geraniums that the empty flower-pots were made a promenade of by thousands of a tiny black species, which looked as if some chimney-pot in the neighbourhood had favoured the locality with an abundant shower of smuts. They were so nimble when I approached to capture them that I only got a few." These are devoid of scales, with globular bodies, and a forked springer. A species of *Degeria* is also common about pots in greenhouses, and other species frequent moss or get under the bark of trees; it is very likely, too, should you see a microscopist turning over bricks that he is in the hunt for some of the Thysanuridae. According to one modern philosopher the individuals belonging to the genus *Podura* were principally designed to furnish food for spiders.

Coming now to the consideration of the various orders of insects, it should be noted in the first place that there is a great difference in the number these contain. Some of them, the Coleopterous order for instance, present us with a long muster-roll, like a modern regiment in the German army, while the meagre list in one or two rather resembles the turnout of some of the attenuated regiments in the petty German States of former times. Working upwards we of course commence with the order Aptera, and find in Britain at least that we have nothing to place in it but the group of fleas, creatures, it might be argued, of very little importance to the gardener. Stop a moment, I am not quite sure of that. It might be also said that, since few gardeners escape the attacks of fleas (unless they are endowed with the peculiar cuticles the fleas won't touch, for some such cuticles there are), they are thus more fully kept on the alert and watchful for the parasitic enemies which affect the plants under their guardianship. "A fellow-feeling makes us wondrous kind" perhaps, and, if a certain poet is to be believed, a shrub covered with galls and blotches produced by insects is as much to be pitied as a man who has been repeatedly bitten by the saltatory insect. And this is not all. It is possible that the larvae of the flea not unusually feed on decaying animal substances, such as wool, feathers, or flesh, therefore aiding in the disintegration and decomposition of substances valuable as fertilisers. That is my belief, and I

observe that even those who propound the theory that the parent flea disgorges a provision of dried blood for the young larvae, also admit that they are not entirely nurtured thus. One author says that the mother returns to feed them, which I much doubt, and I think that anyone acquainted with the irregular wanderings of a flea will not give any of these insects credit for being able to return to the same spot they have quitted, unless it be by accident. Cases are on record where fleas have appeared in hosts in untenanted outhouses, but I do not suppose that this is to be taken as affording any proof that, like an odorous and even more detested insect, the larvae can thrive upon old wood.

The flea, so some assert, is only a degraded fly that has lost its wings and taken to leaping; and, as other speculators suggest—why I cannot tell—that most fleas are of a melancholic disposition, it is perhaps because they are apt to repine over their seeming descent in the scale of life, so different from what Darwinian views might have encouraged them to hope, were fleas as "learned" as they have been shown to be "industrious."

The head of the flea is remarkable for the shortness of the antennae and the prominence and size of the eyes. From the virulent inflammation which occasionally attends a flea-bite one would almost imagine the insect had the power of emitting a poisonous fluid, but as yet our microscopists have detected no traces of poison glands, though within the rostrum there is a formidable array of lancets, which can cut or saw according to circumstances. The body of this insect is flattened and horny, hence the difficulty there is in crushing it, and the leaping is aided by the muscles of the body, not depending solely on the strong array of muscles in the hind pair of legs, which are also spiny. The pale footless larvae of the flea resemble that of the gnat, and when full-fed each spins a separate silken cocoon.

An eastern tradition tells us that Noah on his emergence from the ark produced fleas and all the other creatures that prey on human blood by burning a serpent. Were this so, it is evident that Adam, our great horticultural predecessor, had a happy immunity from such parasitic foes.—J. R. S. C.

#### NOTES AND GLEANINGS.

WE have recently seen growing in the garden of Mr. Ormson, the eminent horticultural builder, at his residence The Bush, Walton-on-Thames, some remarkable fruits of the BARRINGTON PRACH. The Peaches have now been gathered, and many of them weighed 9 ozs. each, some 9½ ozs., and one weighed 11 ozs. These splendid fruits were produced by an old tree on a wall only 6 feet in height. The soil is light and sandy, and the more credit therefore attaches to their production. The fruit crop generally in this garden is very large. Mr. Ormson has erected a fine vinery, and the Vines are of great promise; the bunches of Madresfield Court, but for careless handling in their early stages, would have been worthy of a place at the best exhibitions. The management of this garden is now in the hands of a skilful man, and good results may be anticipated.

THE Rev. George Meares Drought, writing from Ireland, says:—"For three years I have lived in a town, and during that time my sitting-room has been FREE FROM FLIES—three or four only walking about my breakfast-table, while all my neighbours' rooms were crowded. I often congratulated myself on my escape, but never knew the reason of it until two days ago. I then had occasion to move my things to another house, I remaining on for two days longer. Among other things moved were two boxes of Geraniums and Calceolarias, which always stood in my windows, the windows being always open to the full extent top and bottom. The boxes were not gone half an hour before my room was as full of flies as all those around me, and I am now writing at my breakfast-table with twelve dead bodies in the slop-basin, and everything on the table crowding with fresh arrivals. This, to me, is a new discovery, and perhaps it may serve to encourage others in that which is always a source of pleasure, and now proves also to be a source of comfort—window gardening."—(Times.)

WE have received from Mr. Batters, The Gardens, Chilworth Manor, Romsey, Hants, SPECIMENS OF SHRUBS, showing how they "grow, flower, and fruit on a dry and gravelly soil 200 feet above the sea level." The specimens sent of Laurels, Hollies, Bay, Berberis, &c., are remarkable examples of health and fruitfulness. The berries of the common Laurel

are three-quarters of an inch in diameter, and are, Mr. Batters informs us, used by the neighbouring villagers for making fruit pies. They are fleshy, sweet, with an agreeable sub-acid flavour, and are certainly superior to unripe Plums when used for culinary purposes.

On the 17th, according to the ancient custom, the Lord Mayor and the Lady Mayoress received at the Mansion House the Master and Wardens of the FRUITERS' COMPANY, who presented to them a splendid assortment of choice fruit, including Pine Apples, Melons, Pears, Apples, Peaches, Green Gages, and other Plums. The gift was laid out with much taste in the saloon. Some cordial expressions of goodwill were interchanged between the Company and the Lord Mayor, and the interview terminated, as usual, with an invitation to the Court of Assistants to dine at the Mansion House. In olden times the annual gift of the Company to the chief magistrate consisted of twelve bushels of Apples "of various kinds and of the finest description that can be procured." The purchase used to be made in state at Farringdon Market, and the fruit was thence carried in baskets covered with white napkins to the Mansion House. The records add that the Lady Mayoress handed the fruit to her housekeeper, and placed in each of the porters' baskets a bottle of wine. The men were then regaled with a dinner in the Lord Mayor's kitchen, and having satisfied themselves retired, taking with them the fragments for their evening's supper. This old ceremony has not been observed for many years. There were eighty-two Livery Companies, but three are extinct, and among them "The Gardeners' Company." James I., in the year 1605, incorporated this fraternity as the Master, Wardens, and commonalty of the mystery of Fruiterers, and their arms, granted soon after, has the tree of knowledge entwined by a serpent, with man and woman on each side thereof. Their motto is "*Deus dat incrementum*," God giveth the increase. The Fruiterers are governed by a Master, two Wardens, a Court of Assistants, and a Livery. The Company have no hall.

## NOTES ON VILLA AND SUBURBAN GARDENING.

### STREET GARDENS.

THROUGH the late fine weather these little enclosures, where care and attention are paid to them, now present their proper cheerful and ornamental aspect; and in passing along a street one feels it a matter for regret that the line of beauty so conspicuous should be broken here and there by an unsightly and neglected plot; but if anything can be gleaned from the wonderful progress made of late years in town gardening we can safely leave this to be remedied in time. It is not too much to say that there is as much or more variety of design in the laying-out of the little spaces than in many other parts of decorative gardening. There is scarcely two alike, and the great variety of plants grown in them testifies fully the class of plants the owner has a fondness for. I admire this, but I think it would be better if many were not to dwell upon summer bedding plants alone, because there is a barrenness for the greater portion of the year, and which could be easily obviated with hardy and inexpensive plants.

The choice of plants is great even for these limited areas, but as these gardens vary in size considerably, plants must be selected accordingly. I like to see a certain portion filled up with suitable-habited evergreen trees and shrubs, but this must be done cautiously, and overcrowding must be avoided. We sometimes see a Wellingtonia or a Cedrus deodara planted in a garden of only a few feet square, and close to the windows; but these, being large-growing trees, are quite out of place here, but might be admitted where there is a fair scope for them, say of several rods of ground. Neither should other things be planted too close to them. Generally speaking, plants of a compact habit and slow growth should be chosen, such as the green and golden Hollies, Arbor-Vitæs, Phillyreas, Rhododendrons, Thuja aurea, Aucubas, Tree Box, Swiss Junipers, and Irish Yews. These can always be kept within bounds, and may be regarded as always agreeable to look at, and are permanent plants. Space should be allowed for a few other subjects in the flowering way besides a few summer bedding and climbing plants. These are Roses, Hydrangeas, Solomon's Seal, Gladiolus, hardy Lilies, Lily of the Valley, Polyanthus, Primroses, Violets, Hepaticas, and many other hardy permanent plants that would thrive in these enclosures. There are also hardy bulbs, which may be planted in clumps of five or seven to stand permanently. The Winter Aconite, one of the hardiest as well as the earliest in throwing up its yellow flowers, contrasts well with a few patches of Snowdrops, and the Scilla siberica, a blue flower of great richness. Then there is the Grape Hyacinth, of which both the blue and the white ought to be planted, as they contrast well with each other; and the common Daffodil, too, ought to have a place.

All the above to flower next year should be planted this autumn, and they will accommodate themselves to most ordinary garden soil. Of course the ordinary selections of Crocuses, Tulips, Narcissus, and the Hyacinth would materially alter the appearance of the little garden. So far it will be seen that I advocate the mixed system of planting, which I consider looks as well as any in such places, and there is generally some flower or other to be seen during most part of the year. But there is no reason why there should not be a miniature fernery just to accommodate a few of the common sorts found in hedges, or a little piece of rockery here and there, just as taste dictates.

When so many features are needed in such small gardens the attention required is greater, but then if rightly managed the enjoyment is greater also; but to show all off to advantage not a plant should be allowed to over-run its allotted space, and each should be staked to its position in the most natural manner. All weeds and dead foliage should be kept picked off, and everything, even the palings that surround the garden, should be kept scrupulously clean, and then the occupants of the house may sit at their windows and enjoy a homely aspect; and the freshness of the flowers and plants after watering, together with their perfume, creates a treat to be thoroughly enjoyed by all.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### FRUIT GARDEN.

PEARS on the walls have a splendid opportunity to ripen, and if the fruit is not of good quality this year it will be but little use trying the trees any longer. It may be matter of astonishment to many fruit growers to hear that such fine varieties as Knight's Monarch, British Queen, and Glou Morceau are very indifferent from a wall facing west. The weather is so favourable this year that the fruit may ripen well, but light sandy soil on gravel is the worst of all for Pear trees. The hot weather is causing all that has been gathered to ripen rapidly. Williams' Bon Chrétien has been used, and we are now using Fondante d'Automne and Benrê d'Amanlis. The first named is a very richly-flavoured fruit from pyramid trees; the latter is a free-bearing variety, but it is not rich or juicy, and speedily decays at the core; it is a free-bearing sort from a pyramid. It may be well to draw attention to Triomphe de Jodoigne; this is not generally considered a good Pear, nor is it of first-quality flavour, but the tree is a robust grower and a certain bearer. We have just gathered the fruit; it will ripen about the end of October. Still another, which is very little known—viz., Edmund's, an American variety; it is grown as a double cordon, and as such is a very free-bearing sort. Until this year it has been worthless as regards flavour, now the fruit is ripe and of very fair flavour; it is gritty at the core, and cannot be recommended while there are such sorts as Louise Bonne of Jersey ripening at this season.

We are preparing ground to plant-out a few fruit trees this autumn. The best time to plant is in November, but the ground ought to lie for about two months to settle, and besides soil that is freshly turned up is not in good condition to be planted upon immediately. We trench deeply, removing if necessary some of the stony soil from the bottom of the trench, and adding clay loam in its place. We tried chalk in the bottom of the trenches on one occasion, but were not favourably impressed with the result of the trial. It may be necessary to add manure; if so, it ought to be well decomposed and applied sparingly.

It is the fashion with some to take the Strawberry runners early in August and prick them into beds closely together, and to plant them out when well established; they will be ready at this season, and ought to be put out at once. It is not possible that such plants can carry a crop of fruit next year, but they must be kept free from weeds, and the runners must be removed, so that a season is lost. Our plants put out early in August are now very large and in the best possible health; the runners are removed frequently, and the ground hoed as often as it is required. Red spider has been troublesome, but syringing the plants with soot water is the means of destroying the spider, and the leaves become of a rich healthy green.

### VINES.

Nothing can be done as yet in the early houses, but before writing of them again in the "Doings" the Vines will probably have been pruned. We admit air night and day, so that the house may be kept as cool as possible. Most of the old leaves have fallen, and the buds continue to start into growth. These growths are stopped as soon as they are formed, as it is not to the advantage of next year's crop to encourage root action now. When the Vines are clothed with foliage we would not be afraid to keep the house warm, for as long as the leaves are attached to the wood the buds continue to develop the incipient growth for next season. Do not allow red spider to find a home on the Vines. Even if no trace of this scourge is perceived it is quite as well to syringe once a week at least as a preventive.

In the late houses all fruit is ripe, and the only care necessary

now is to prevent any decay from spreading on the bunches, nor should any dust be permitted to lodge upon the berries. This cannot be avoided if the vineries are situated near a public highway; the dust that arises from the traffic penetrates to the Grapes even if gauze is placed over the ventilators. In the matter of mouldy berries from now until the leaves fall we find the Grapes require daily attention. A pair of scissors is kept in the vinery, and if mould is noticed the berry is removed before the decay has time to spread. If it is necessary to apply artificial heat to the vinery, it is best to do it in the daytime. Let the pipes be warmed sufficiently by 2 or 3 p.m., and then stop the flow of the water if the house is connected with others; if it is not, the fire ought to be lighted in the morning and allowed to die out by midday. When there are no plants in the house the difficulty is easily overcome, but in many places there is no choice in the matter. When plants require water it ought to be applied in the morning, so that the damp may evaporate as much as possible during the time the ventilators are open to their fullest extent.

Many persons will be preparing to plant their vineries, not only for late but also for early fruiting. Lady Downes' is still the best variety for very late purposes; it is also a Grape that is esteemed by some at a time when Alicante, Mrs. Pince's Black Muscat, or Gros Guillaume can be had in good condition. If we were to plant a house for very late Grapes, say for use from January to May, it would be with Mrs. Pince, Alicante, and Lady Downes; half of it would be occupied with the last-named and half with the other two, planting most of Alicante as being the most certain of the two. If no Muscats were grown in any other vinery it would be very desirable to find a place for Muscat of Alexandria. The same treatment is suitable for all of them.

#### CUCUMBER AND MELON HOUSES.

Our plants for the winter Cucumbers were planted some time ago, and are now in bearing; if they had to be cropped heavily they would not bear well at midwinter, but by very light cropping at this season Cucumber plants will continue to bear all through the winter. Where a good supply has to be maintained it is better to allow the plants to become exhausted by Christmas, and to have a second set to begin to bear from that time onwards; they ought to be planted out by the middle of October. It is well to grow the plants with plenty of air when weather permits, so that a healthy growth may be made to form a good foundation to start upon for future crops; above all, see that the plants are kept clean and free from all insect pests. This has been repeatedly urged in these papers as advice of the first importance; for if red spider or thrips continue to suck the juices of the leaves at a time when all the strength of the plant is required to produce fruit, the result may be predicted.

There is one thing which may seem of minor importance, but it is not so, and that is the position of the soil or compost in which the Cucumbers are planted. This ought always to be raised high enough to allow the sun to act upon it, for if it is placed down in a pit where the sun's rays are intercepted by the front wall, the plants cannot possibly do so well. It is the minor details that are the means of securing success in this as in greater things. The intelligent cultivator will take note of the circumstances under which he is placed, and will act accordingly; but this ought never to be lost sight of—that sun and air are the grand agents that will, if utilised on the best principles, contribute more than all the rest to the cultivator's success. The weather still continues most favourable for Melons, and the autumn crops have been better than those obtained at midsummer, and very little artificial heat is required to ripen them.

#### GREENHOUSE AND CONSERVATORY.

It is now a busy time with Chrysanthemum growers. The ardent cultivator is constantly amongst his plants, tying and training the specimens, and "setting" the blooms on the plants intended to produce cut flowers. This last operation requires some knowledge of the different varieties, as some take longer to open than others, and if they are all "set" at one time they will not be all ready as they ought to be on the exhibition day. All the side growths that start under the flower-buds must be removed as soon as they can be taken hold of with the finger and thumb. When the buds are set manure water is applied at every alternate watering. This also must be a matter of experience, for some of the sorts take as much manure water as the roots will appropriate without injury, while others may require but little or none at all. There are flowers that will be coarse under any treatment, but manure water will be the means of producing this objectionable feature in the flowers.

True or perpetual-flowering Carnations are now swelling their buds rapidly, and the first of them will be in flower in October, a succession of flowers are then obtained from two or three dozens of plants for the next twelve months. Last year's plants are still flowering, at least a few of them, as the greater portion have been removed from the house for want of space. Stage Pelargoniums are now ready for repotting; the old soil ought to be shaken away from the roots and the plants be repotted in much smaller pots. Azaleas and other New Holland plants are left out of doors while the weather is favourable; if a wet

period should set in all of them will be better indoors.—J. DOUGLAS.

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

ALEXANDRA PALACE (Potatoes).—September 29th and 30th. Mr. P. McKinlay, 23, Upper Thames Street, London, Hon. Sec.  
JERSEY.—Autumn October 18th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

### TRADE CATALOGUES RECEIVED.

James Dickson, Newton Nurseries, Chester.—*Catalogue of Dutch Flower Roots, Roses, and Garden Requisites.*  
The New Plant and Bulb Company, Lion Walk, Colchester.—*List of Japanese Lilies, Orchids, &c.*  
Smith & Simons, 36, Howard Street, Glasgow.—*Catalogue of Trees, Shrubs, and Bulbs.*

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

REINHOLD CLAUDE DE BAYAT PLUM (G. S.).—The Plum enclosed was quite sound. We do not grow this variety in the orchard house, but out of doors it is so uncertain that we thought of discarding it. Probably a maggot inside is the cause of the defect; we have often had the fruit injured by them when no trace of its entrance could be observed outside. We cannot account for it in any other way.

LARGE STRAWBERRIES.—"C.B.G." wishes "AN EXPERIENCED GARDENER" would tell how he cultivated the plants which bore the large Oscars mentioned in this Journal, August 12th.

PEARS RUPTED AND SMALL (L. J. K.).—The disease and the inferior size are evidence that the soil is very much too poor. It should be liberally manured at once, and the surface kept mulched during the spring and summer.

MESSEMBRYANTHEMUM CORDIFOLIUM VARIEGATUM FROM SEED (Y. W. B.).—It may be raised from seed, and the best time to sow it is in July, so as to have the plants well established before winter, they either being pricked off in pans or potted off singly, keeping rather dry during the winter. Sow in gentle heat in February, and grow on in gentle heat, pricking off the seedlings when large enough to handle, hardening well off before planting out.

VACCINIUM LATIFOLIUM (Idem).—We do not know that it has any "use," only an ornamental evergreen shrub requiring to be grown in peat soil.

PALM AND DRACENA SEED SOWING (A Young Gardener).—Sow them all in strong heat in February, and in a compost of two parts fibrous peat and one part turfy loam, with a free admixture of silver sand, covering each the diameter of the seeds and keep moist. A bottom heat of 90° is not too much, and top heat of 75° to 90°.

RAISING VARIEGATED HOLLIES FROM SEED (Leybor).—The seed will germinate, and a majority of the seedlings will be green-leaved, but these may often do throw off variegated parts. These may be propagated by grafting, or the green parts cut away. The seeds will not vegetate until the second year. Both green and variegated Hollies may be raised from cuttings—the ripened shoots of the current year put in now in sandy soil surfaced with an inch of sand under hand-lights on a north border. Hollies have the male and female organs in the individual flowers, but some trees do not produce berries, they being for the most part very vigorous.

HYACINTH AND TULIP SEED SOWING (F. W. H.).—Sow both now in light sandy soil in a sheltered situation, covering about a quarter of an inch deep, and afford protection from frost in severe weather, or defer sowing until March, and the seedlings will appear about June, and are not to be taken up until the July following twelvemonth, planting them again in October.

MARSHAL NIEL WORKING ON HYBRID PERPETUAL (Idem).—It would succeed admirably, the Perpetual upon the Briar being of free growth.

DISEASED POTATOES, ARE THEY INFECTIOUS (P. M.).—If the season be favourable, Potatoes planted in ground where diseased tubers have been allowed to rot will not be affected. We have known the experiment purposely tried. At the same time it is not an advisable practice to grow Potatoes on the same plot the following year.

FUNGUS ON PEAR LEAVES (J. N.).—The brown projecting patches beneath the leaves are a fungus, *Rosella cancellata*. Gather every affected leaf and burn it; do not let any remain on the ground—burn all. It is very destructive.

LADY DOWNES' SEEDLING GRAPE (J. A.).—This variety of Grape will succeed in a house where it can have a night temperature of 65° when the fruit is setting. This it can have in a greenhouse about the middle of May, after that no artificial heat is required until the time of ripening—about the end of August. The greenhouse ought to be shut-up at six o'clock during the summer months. We do not recommend Lady Downes' to be planted in a greenhouse, but you asked if it could be grown. We may as well say that by far the best Grape for greenhouse culture is Black Hamburg.

STRAWBERRIES FOR LONDON MARKETS (R. W.).—Keene's Seedling for early produce, and Dr. Hogg for succession.

**PRACHES FOR SOUTH WALL (R. H. A.).**—The following are in the order of their ripening:—Early Beatrix, Early Rivers, Grosse Mignonne, Noblesse, Ballegarde, Osprey, and Lord Palmerston. The Nectarine may be Balgowan.

**BEES EATING FRUIT (J. F.).**—There is no mode of destroying the bees, as they will not go into bottles as wasps will. Bees do not attack fruit except in very dry seasons when flowers are deficient in secretions. The most efficient protection of the fruit would be to fasten gauze over it.

**A DOZEN SUPERIOR GARDEN ROSES (J. Kelly).**—The following are the best out of some 850 varieties which we have proved within the past seven years. All are perpetuals except one, and that one a Tea-scented—viz., Gloire de Dijon, the best "one" Rose for the million, and the best "one" red Rose is Alfred Colomb. Baroness Rothschild, Charles Lefebvre, Comtesse d'Oxford, Dupuy-Jamain, Edward Morren, John Hopper, La France, Madame Victor Verdier, Semestre Valisee, and Capitaine Christy. You will want whites, and we name two, Boule de Neige and Perle des Blanchés. Yellows are Bêve d'Or and Perle de Lyon, both Teas. Bessie Johnson, Hybrid Perpetual, is, perhaps, the sweetest of all Roses, always excepting the Tea-scented "Odorata," bluish, the finest scented of all. We do not, however, advise it for your purpose, but all the others are good growers, and are suitable alike for standards or dwarfs.

**ROOT-PRUNING FRUIT TREES (F. J.).**—It should not be done until the leaves are beginning to fall, certainly not before the 1st of next month. Early in November is quite early enough.

**TAKING-UP MASTER CHRISTINE GERANIUM (Idem).**—They being plunged in the pots will be lifted more certainly than those planted out, and being done before frost, they, kept over the winter, will flower more freely than young plants. The roots will have extended beyond the pots and over the rims. They should be turned out of the pots and have most, if not all, the old soil removed, the long straggling roots shortened, and the plants returned to the same size of pot, which should be cleaned. Any straggling growths to be cut back, and all the large leaves removed. They should have but little water until established, taking care to pot them into moderately moist soil, neither wet nor dry, but a mean of the two.

**REMOVING THE HAULM FROM POTATOES (S. E.).**—We have submitted your letter to the author you quote. He replies that there is no practical danger of the tubers growing again in the ground. Only once has he found that to be the case—viz., in the hot season of 1868, and the wet and warm autumn following, and even then the growth of the current season's tubers was not general, and was confined to the earliest kinds. Dalmahoy's the same season remained perfectly dormant. *Cyclamen repandum* is in colour reddish lilac. Your white variety, if it flowers in the autumn, is *C. albidum*; if in the spring, *C. albidum*.

**FUNGUS (X. X. X.).**—It is not clear what species you have in view under *Boletus aureus*. Schaffer's *B. aureus* is very doubtful. Perhaps you have *B. granulatus* in view, if so, Pearson and Withering describe it as edible, but we have not tried it, and we know one of its allies to be dangerous. Or your plant may be *B. variegatus*; if so, its qualities are doubtful. Both the above plants belong to Schaffer's old *B. aureus*. You should work with the volumes of Frise or Berkeley.

**FRUIT NAMING.**—Many times have we given notice that we cannot name more than six specimens at a time from any applicant, yet multitudes send us far more than that number. Our rule must be like the laws of the Medes and Persians, "which altereth not." It is no easy task to identify any fruit now that there are thousands of varieties.

**NAMES OF FRUITS (H. G. M.).**—1, Passe Colmar; 2, Fondante d'Antonne; 4, Beurré d'Arenberg. (Mrs. Henderson).—It was quite decayed when it arrived. (J. W.).—Winter Hawthorn. (F. J. K.).—5, Beurré Sterckmans; 6, Comte de Flandres; 7, Williams' Bon Christien. (Geo. F. Barrell).—1, Court-Pendu-Plat; 2, Northern Greening; 3, Bedfordshire Foundling; 4, Maréchal de Cour; 5, Beurré d'Arenberg; 6, Comte de Flandre. (Somerset).—Imperiale de Milan. (T. Nial).—1, Washington; 2, Victoria; 3, quite rotten; 4, Jefferson. (G. J. W.).—24, Cockle's Pippin; 21, Braddick's Nonpareil; 25, Beauré Nonpareil; 27, Christie's Pippin; 1, Louise Bonne of Jersey. (G. H. Fitzherbert).—Pears: 1, Beurré Diel; 2, Desirée Cornélius; 4, Aston Town. Apples: 3, Yorkshire Greening; 8, Nelson Codlin; Selwood's Reineette; 6, Lewis's Incomparable. (Comar).—1, Loan's Pearmain; 8, Golden Reineette; 4, Vicar of Winkfield Pear. (Donnaught Subscriber).—1, Oakin; 2, Reineette du Canada. Pears: 1, Beurré Clairgean; 2, Williams' Bon Christien; 8, Brown Beurré; 4, Urbanista. Plum: Prince Englebert.

**NAMES OF PLANTS (J. P. P.).**—The specimens were dried-up, and some only leaves.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### CUPS AND ENTRY FEES.

WHEN writing the other day of Mr. J. K. Fowler's establishment of poultry at Aylesbury we alluded to his cups and plate—trophies of past poultry shows, and the differences between them and the cups sent out in the present day. As we said then, it really seems in these times that so long as an article can be called a cup it does not matter what it is like. But really this should not be the case. It is all very well to win one or two such articles, but after that it comes rather slow. Once the glory and honour of winning the maiden cups are over, most fanciers like either to have something useful or the value in cash. We really sometimes think that the cup system of the present day is going too far. When we see a £2 2s. cup given as a first prize in every class throughout a schedule we begin to think that we may indeed say, "Somewhat too much of this."

A few years ago a specimen that had won a cup was a marked bird. Its title, "cup winner," showed that it was above the ordinary run of prize birds, and that it was a specimen to be proud of; but now everyone has cup specimens, for we see advertised cup pens of poultry for a few shillings, and eggs from cup birds for 8d. or 4d. each. This almost makes us weary of cup-winning, and desirous rather of good money prizes and a champion cup or so every now and then as a *bonne bouche*.

We fear there is a tendency, too, for committees to value the cups of the present day at more than they are worth to make them flashy and acceptive baits—in a word, to catch exhibitors with them. We are alluding here, of course, to those exhibitions who actually give cups and not the value in money; but we would not for a minute wish to be understood to allude to all exhibitions—far from it, as we have had ourselves splendid value in plate; but we say we think there is a tendency to this over-valuing of plate. We know of two cases which came under our own eyes, and have heard of very many more. In the first case the cup was valued at £5 5s., and was won in the very north of England, where it was seen by an exhibitor and noted as a fair five-guineas' worth. When, however, it arrived at the winner's place of residence the same cup which was on exhibition at the show never came, but a petty thing that a child could easily have bent into any shape, and which was valued by a silversmith at 23s. by weight.

The other case was a champion cup, where the article in question was valued by a silversmith at 60s. by weight, and it was stated to be in the schedule a 210s. article. These things make beautiful puffs in an advertisement, but are hardly satisfactory to the winners; at least so we think. Those shows who give cups but allow the winners to take the value in cash we can say nothing about, as the arrangement is all fair and above board; but why in that case they should not be called first prizes we cannot understand, for the winner is in those cases able to put the money against the corn bill, or buy any other article as is preferred. We confess we would like to see the value of a cup-winning specimen go back to its old rate, and we can never see this while so many paltry little cups are being given and being won so easily everywhere. Local cups, too, we do not approve of, for in many cases the winners are wretched specimens, winning in poor competition, and yet the birds go forth to the world in a silver cloak, and sometimes are the means of great disappointment to our less experienced poultry friends.

In a schedule like that sent out by the Alexandra Palace we think the cup arrangement very good for the most part, as to pick out the winners for a champion cup among the pens we shall doubtless see there would be a simple impossibility, and so to give at a show of that kind a good cup or its equivalent money value for the various classes of a breed is well and good; and besides, the fact of a Palace winner alone tells the merit of a bird, and carries its value on its back; but it is at the little shows—at the small mixed-up-classes shows, that we want to see the cup system altered.

At the same time we think the entrance fees should to some extent be charged according to the value of the cups and prizes offered. It certainly is not fair for the same fee to be charged in a class where, say, only £2 can be won, as in a class where double or treble the value is offered. Now, the Polish people at the Palace pay 7s. 6d. for the chance of winning a £4 4s. cup where the first prize is £2, while the Brahma people pay only the same money for the certainty of £10 10s. and £7 7s. prizes. Of course the chance of winning is much more remote in the latter cases, and there will be a much greater number of entries, but still the arrangement to us hardly seems fair. We confess of all schedules we think Oxford stands alone for the even way it distributes its money, and the low entry fees it charges—viz., only 5s. for 60s. first prizes. We have noticed of late that two or three shows have made a different tariff of entrance fees for the different sums expended in prize money, and have noticed it with pleasure; we hope others will copy their example, for we really think that high entrance fees with poor prizes keep down the number of entries in many classes at shows to an immense extent. We sometimes wonder if it would be possible to have one recognised scale of charges for entrance fees. It would simplify matters very much, and put shows on a much more even basis. Were we to draw up such a scale we should say they should be something in this proportion: 8s. for a £1 first prize, and then 1s. forever 10s. afterwards, which would make a 7s. entry fee for a £8 first prize. This we should call a fair charge, and then if there were one or two champion cups to be competed for another 6d. per pen could be added. Were such a scale adopted—and we think all would consider it reasonable—we believe that much greater satisfaction would be given, and the exhibitions would be more even in quality and quantity than we now find them. Anyhow, we would always have a third prize. We are sure this is a loss to many a disappointed one, and if it only saves the stakes it is something in these hard times.—W.

### ALEXANDRA PALACE POULTRY AND PIGEON SHOW.

AT the request of numerous exhibitors we have decided on allowing more than one entry to be sent in a basket, but of course each compartment must be properly labelled, and if any of the birds be sold the exhibitor will be charged for a new basket. Respecting the question of conveyance, perhaps we may just state that birds coming from the north will be delivered direct at the Alexandra Palace, and so save the

expense and delay of crossing London. We would also call attention to the fact that this is only a three-days show. The birds are not required to be delivered until Monday, the show closing on Thursday, so they ought to reach their homes on Friday, or at the latest on Saturday, thus preventing the birds being confined on Sunday, which so many exhibitors object to.—W. J. NICHOLLS, P. H. JONES, *Hon. Secs.*

### POULTRY FARMING.

ALTHOUGH I had hoped to have seen several statements from others to confirm my few remarks published under the above heading in your issue of August 28th, I now submit for your inspection, as promised, an exact copy of my books, taking date in each case from September 1st, 1874, to September 1st, 1875.

Poultry to me has always been a hobby, but when first I entered into it I had no idea of its profits nor of working on so large a scale; and though I fear I shall be charged by some with much seeming egotism, still I can assure your readers I have no other object than to persuade those who love a country life and who will devote their time to this means of stock-raising, that it has interests new and fresh coming every day, and will assuredly bring a comfortable income to enjoy it. Few, perhaps, would go into the detailed trouble I do, as I know each week exactly how many head of fowls are in stock, and upon picking up any fowl can tell the month it was hatched in (i.e., by its marking).

I never allow anyone to gather the eggs nor to sit broody hens, but when they have taken to the nest I prepare thirteen eggs, marked in ink with date upon them, place them in a clean box in the hatching room, and after sunset take the broody hen from where she has chosen to sit and put her on to the eggs and close her up for thirty-six hours, or till the next morning but one. I am particularly lucky in hatching. I am satisfied that almost all chances of success rest upon the eggs being closely set on at the commencement, and if left after that for hours they will scarcely be hurt.

On September 1st, 1874, I possessed a stock of sixteen cocks and 169 hens and pullets. At that time having several sittings of eggs about to hatch for successive laying in March, April, and May, 1875, when most winter and spring layers are all at a time broody, the last lot hatched in 1874 being October 3rd, making at that time seventy-nine additional chickens, of which six died before Christmas. Six Geese, two ganders, four Turkeys, twelve Ducks, and three drakes, all for store; fourteen young Turkeys, fourteen young Geese, eighteen young Ducks, and twenty-two young cockerels for killing.

From this number of poultry I have raised, sold, and have balance in hand, and present stock, less that in hand 1st September, 1874, and the fifty-three fowls and five Ducks bought last August and added to pens, as follows:—760 fowls, 723 Ducks, 70 Geese, 41 Turkeys. Sold 16,389 eggs, producing a total of £268 14s. 8d., less cost £145 17s. 10½d., leaving as balance of profit £122 16s. 4½d., besides supposed value of feathers, £4, and of manure, £3, not credited against cost—really making £129 16s. 4½d. profit. In the detailed cost account packages, cartage, advertisements, stationery, postage, &c., amount to £18 0s. 6½d., against £38 4s. received for sittings of eggs sold; but it must also be remembered that through the advertising columns of the various papers there were also sold chickens, Ducks, Geese, and Turkeys amounting to £63 3s. 1d., which, it is probable, would not have been sold at those times and prices had it not been for advertising, so that it is estimated by me that the £6 7s. 8d. advertisement-costs induced sales in a total of £86 7s. 1d., which were attended with further expenses of £6 12s. 10½d.

I may also call attention to the prices asked for sittings of eggs sold, all of which were warranted fertile, and I was but asked to replace fifty-two out of a total of 2538—viz., eggs from Dark Brahmas; Dark Brahma hens running with Dorking cock; Dark Brahma hens running with Black Red Game cock, all at 2s. 6d. for thirteen, packed, and all from first-class birds. Rouen Duck eggs, 6s. 6d. for thirteen. The five Ducks cost £9 10s. East Indian Duck eggs, 5s. for thirteen. The Turkey eggs, bred from a cock now weighing 35 lbs.

If it be possible, then, at such prices and at so great an expense of feeding, as I consider my fowls have been extravagantly fed, how much more rather can be realised by those prizetakers and breeders advertising at 2½s. for thirteen eggs, and if unfertile second sitting at half price, making 1s. 2½d. per egg?

Had I been fortunate enough to have hatched say half of the expensive eggs bought by me, and sold at fair prices the produce therefrom, a greater profit would certainly be shown, as this year I really never sold but two birds at 7s. 6d., except broody hens, and after those nothing over 3s. each, and these cost quite as much to rear as those more extravagantly priced. However, everyone has a right to his own mode of conducting his business, and I have only attempted to show that with proper and above all prompt attention to poultry, as whether "hail, rain, wind, or snow," occurs, it will not brook delay, there is a livelihood for many who have plenty of time to devote to such a purpose.

I have added many valuable additions to my poultry stock, and next season intend, as in 1875, to warrant every egg sold to be fertile; and a new feature at this poultry farm will be that I shall undertake for one and all who entrust their eggs to me to provide broody hens, and set them here in a shed with 150 nests erected on purpose, and rear the chickens up to one month old at a small fixed fee. I am now drawing out in print a list and catalogue of various pens of fowls kept, and bearing some valuable information to all poultry fanciers.—GALLINACULTURIST, *Hampton-in-Arden.*

### CREWE POULTRY SHOW.

SEPTEMBER 17TH-18TH.

As to the general quality of the birds shown, nothing so good has taken place at any of the previous shows held at Crewe; and the tent arrangements were praiseworthy.

Game cockerels (any variety) headed the list, and, noted as it is, very rarely have so well shown a number of Brown Reds been seen in the neighbourhood. The two chief prizes were taken by Brown Reds; the third premium was awarded to a Black Red. It is worthy of note that some few of the most showy birds when "handled" proved to be wry-breasted, a fault for which every other good property cannot atone. It is well here to remark, too, on a great mistake now too general in the dubbing of Game fowls—viz., cutting them too closely in the wattles, as it entirely destroys the proper outline of the throat, besides failing to develop length of head, as desired by the party operating. It quite spoils an exhibition bird. The *Dorkings* and *Spanish* were both very excellent classes; many of the pullets having been raised early this season, were, however, after laying their first eggs, deeply moulting. In *Cochins* Mr. Sedgwick, and in *Dark Brahmas* Mr. Ansell, competed with grand pens, shown in exquisite plumage. *Poles* were fine, though not numerous; and *Orpingtons* were quite the best variety of the French fowls. *Game Bantams* were shown in capital trim, and some very fair Silver-laced Sebrights were winners. *Hamburghs* were well represented by capital pens from the well-known yards of the Duke of Sutherland.

In the classes for *Waterfowls* the restriction of birds of 1875 operated injuriously to a few pens of the best birds shown. We think another year such a restriction would be well withdrawn altogether, and yet more especially as to fancy *Waterfowls*, as the young of these birds are not yet in plumage. The weather was delightful, and the entrance gate consequently a success.

GAME.—Cockerels.—1, R. Ashley, Nantwich. 2, J. Chesters, Nantwich. 3, T. B. Lowe, Leicester.  
DORCKINGS.—1, Rev. E. B. Charlton, Lichfield. 2, J. Walker, Roobdale. 3, Mrs. E. Williams, Hemley Barrow.  
SPANISH.—1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

### UTTOXETER POULTRY SHOW.

SEPTEMBER 16TH.

THE Judge was Mr. Teebay, and he expressed his opinion that it was the best show of young birds he had seen this year. There were 206 entries, a considerable increase on former years. The following were the awards:—

GAME.—Cockerels.—1, E. S. Godsell, Stroud. 2, G. Bagnall, Draycot. 3, G. Bagnall, 1, G. Bagnall, 2, W. C. Phillips, Worcester. 4, W. T. Everard, Ashby-de-la-Zouch. 5, Duke of Sutherland.  
SPANISH.—1, H. Blower, Wolverhampton. 2, E. Jackson, Wolverhampton.  
DORCKINGS.—1, J. Walker, Roobdale. 2, G. A. & W. H. Crewe, Etwell. 3, Grey or White.—1 and 2, Lady Bagot, Bagley.  
COCHINS.—1, C. Sidgwick, Keighley. 2, Mrs. Allsopp, Worcester. 3, Any other variety.—1, C. Sidgwick, 2, J. K. Fowler, Aylesbury.  
BRAHMA FOOTRAS.—Dark.—1, H. Lingwood, Needham Market. 2, Bridgewater and Yoxall, Wednesbury. 3, H. Lingwood. 4, K. Hyde, Hyde. 5, R. E. Horsfall, Liverpool. 6, T. A. Dean, Hereford. 7, P. Haines, Falmouth, Diss. 8, T. A. Dean.  
LIGHT.—1, R. E. Horsfall, Liverpool. 2, T. A. Dean, Hereford. 3, P. Haines, Falmouth, Diss. 4, T. A. Dean.

**HALLMARKS.—***Golden pencilled*.—1, C. J. Jenson, Peckham. 2, Duke of Sutherland. *Golden pencil*.—1, Duke of Sutherland. 2, Duke of Sutherland. *Golden speckled*.—1, Duke of Sutherland. 2, T. Bealson, Hamford. *Silver pencilled*.—1, Duke of Sutherland. 2, S. W. Hallam, Leicester.

**HOPDANS.—***Cocherels*.—1, J. E. Clayton, Stockport. 2, W. O. Quibell, Newark. *Yellow*.—1, J. K. Fowler. 2, E. B. Wood, Uxminster.

**ORRIS-GRUBS.**—1, Rev. J. G. B. Knight, Ripley. 2, R. B. Wood.

**TURKEYS.**—1, W. Wykes, Hincley. 2, Rev. N. J. Ridley, Newbury.

**CHICKEN.**—1, J. Walker. 2, J. Milne, Birkenhead.

**COCK WHITE.**—1, J. K. Fowler. 2, T. Beam, Sassen. 3, R. Kendrick, Llan. 4, J. Walker. *Any other variety*.—1, J. Walker. 2, M. Leno, Dunstable.

**EXTRA CLASS.**—1, Duke of Sutherland. 2, Miss A. Brooke, Shrewsbury.

FARNWORTH AGRICULTURAL SOCIETY'S  
POULTRY SHOW.

This was held at Farnworth, near Warrington, on the 18th inst.

**DONKEYS.**—*Chickens*.—1, J. Walker, Rochdale. 2, L. Pilkington, Widnes. 3, W. H. Crowe, Derby.

**WATERBURY.**—*Chickens*.—1, 2 and 3, T. F. Ansell, St Helens. *Chickens*.—Cup, 1, 2 and 3, T. F. Ansell, St. R. Pritchard, Tattenhall. No. F. Brookwell, Wigan; J. Bennett, Bishfluff.

**COCKS.**—*Cinnamon* or *Bug*.—1, E. F. Perivall, Northenden. 2, J. Walker. 3, C. Sidgwick, Kedgeley. *Chickens*.—1 and 2, C. Sidgwick. 3, W. Stanton, Driffield.

**COCKS.**—*Purridge-feather*, or any other variety. 1 and 2, C. Sidgwick. 3, F. Bennett, Bishfluff. Any variety than *Cinnamon* or *Bug*.—1, E. F. Perivall. 2, T. F. Ansell.

**GAMES.**—*Browned Red*. *Chickens*.—Cup and 1, J. Fletcher, Stoneolough. 2, B. Buxley, Winsford. 3, J. Linsell, Halshaw. *Brown-browned Red*.—*Chickens*.—1, J. Carlisle, Kirby. 2, G. C. Barnett, Kirkhead. 3, A. Clayton, Bradford. 4, J. K. Mallin. Any other variety. *Chickens*.—1, J. Baisell. 2, J. F. Walton, Ratonhall. 3, M. Jowett, Bradford. 4, G. Holmes, Driffield. *Cock*.—1, C. W. Brerley, Middleton. 2, Duke of Sutherland. 3, J. F. Walton, Rawtenstall. 4, L. Pilkington. 5, J. Chester, Manwith; C. W. Hierarchy.

**SPANISH.**—1, E. Walton. 2 and 3, J. Powell, Bradford. 4, E. Jackson.

**HAMPSHIRE.**—*Golden-pencilled*.—*Chickens*.—1, G. & J. Duckworth, Ascering-ton. 2, Duke of Sutherland. 3, H. Beldon. *Single*.—1, W. Spackman, Nantwich. *Silver-pencilled*.—*Chickens*.—1, H. Beldon. 2 and 3, E. W. Bracewell, Kirby. 4, H. Pichler, Kirby; Duke of Sutherland.

**HAMPSHIRE.**—*Golden-pencilled*.—*Chickens*.—1, H. Beldon. 2 and 3, G. and J. Duckworth. 4, H. Pichler. *Silver-pencilled*.—*Chickens*.—Cup and 1, Duke of Sutherland. 2 and 3, J. Fielding, Newchurch. 4, Ashton & Booth, Broad-bottom.

**POLSKA.**—1 and 2, H. Beldon.

**ANY OTHER VARIETY.**—1, H. Beldon. 2, W. J. Johnson, Liverpool. 3, Rev. J. C. B. Smith, Ripley &c. H. Pichler (Black Hamburg). 4, C. Sidgwick, Kedgeley (Black Hamburg); J. Sandeman, Dunce.

**MILKING COWS.**—*Chickens*.—1 and 2, J. M. Parry, Newton-le-Willows. 3, C. Smith, Wigan.

**BARNS.**—*Gams*.—*Cock*.—1, E. Walton. 2, R. Brownlie, Kirkcaldy. 3, E. Bell, Hurton-on-Trent. 4, J. E. Fletcher; M. J. Nelson. *Chickens*.—1, E. Walton. 2, G. Marples, jun., Wavertree, Liverpool. 3, J. R. Fletcher. 4, G. C. Barnett, Kirkhead. Miss M. J. Nelson, Hexham.

**WATERBURY.**—*Chickens*.—*Vegetable*.—Cup and 1, H. Beldon. 2, G. Hall, Keadell. 3, H. B. Smith, Broad-bottom. 4, R. H. Ashton, Mottram.

**DUCKS.**—*Rouen*.—Cup, 1, and 2, W. Evans, Whiston. 3, P. Unsworth, Newton-le-Willows. 4, E. Gladstone, jun., Broad Green (3); W. Evans; G. Butterworth, Liverpool; J. Brookwell, Wigan; F. Unsworth, Aylesbury.—1 and 2, J. Walker, Rochdale. Any other variety.—1, J. Walker. 2 and 3, H. B. Smith. 4, J. Walker. H. B. Smith.

**GEES.**—1 and 2, J. Walker. 3, H. Deacon, Appleton.

**TOMATE.**—1 and 2, J. Walker. 3, J. Brookwell, Wigan. 4, J. Knight, Farnworth.

**JUDGES.**—Mr. James Dixon, Bradford; Mr. George Fell, Warrington.

**STAMFORD POULTRY SHOW.**

The Northamptonshire Agricultural Society is erratic in its movements, like others of the same genus. We have followed it from Weedon to Kettering, and thence to Northampton, and now this year we find the tents pitched and the flags flying in Burghley Park, near Stamford. The schedule since last season has been entirely revised and much more money spent upon it. Still we doubt if all the changes are desirable; for instance, we find all the Game, Cochins, Brahmas, and Hamburgs classed in groups irrespective of colours. It is true each group has four classes, two for adults and two for chickens; but at this season of the year old birds must appear at a disadvantage, and it is not fair for all colours of Cochins or all varieties of Brahmas to compete together. Mr. Teebay awarded the prizes, and his awards were very favourably received. The classes were mostly well filled, and the meeting on the whole an unusually successful one.

Coloured *Dorkings* were very good. The adult cocks were mostly out of feather, except the first-prize bird; he was excellent, and deserved his place. Cockerels were a nice lot. The *Dorking* coop fell to a very fine hen in capital condition and feather. Pullets were also a pretty lot. White *Dorkings* did not muster well; the winners were, however, worthy specimens. *Game* made four most interesting classes. The old cocks were for the most part losing their feathers. The cockerels were good. A very forward and nicely-dubbed *Duckwing* won the sup. The hens and pullets formed two capital classes, especially the latter. We were altogether much pleased with the young *Game* classes at this Show. *Spanish* were moderate; the lady element much superior to the gentlemen. The coop fell to a grand old hen in good order. The winning pullet must have, however, pressed closely on her. Second and third also good. *Cochins* were good classes, but the old cocks were also in deep moult. In cockerels a good *Partridge* was first, and as yet a rare but most promising White second. In hens a fine White was first-and-sup. the same bird that we noticed at St Ives was

believe. The Cochin pullets too were a pretty lot. The second White was extremely good in all points, and third an admirable Partridge. *Brahmas* were a grand collection. Mr. Lingwood, in reply to our appeal from Birmingham as to where he could possibly be, here responded, and won the Brahma cup and all the four Brahma first prizes. There were other good birds in these classes, and Mr. Long sent some capital Lights, but all were far behind the Creeting team. The Brahma pullets were, however, certainly a very remarkable lot, and we noticed many birds worthy of prizes. *Hamburghs* were fairly represented, considering the insult they received by the classification. This no doubt kept many of our Hamburgh breeders away, but, as we have before stated, we can never rely on a good exhibition of this breed far away from the north. A nice Silver spangled won the cup. We notice Mr. Leno's name in these classes, and welcome him as a fresh addition to the midland Hamburgh exhibitors, and hope he will be a permanency. Mr. Long showed a good cockerel in smart condition, and Messrs. Faulkner and Judson had some well-marked Golden-pencils. The *Bantams* were good, but beyond the winners nothing calls for much notice. The Silver-laced were finely-marked birds, and we noticed some good Blacks and a very pretty pen of White-booted. The Any other variety classes were splendid, and the entries numerous. Crêves won the Hon's share of the prizes, including the cup and all the four firsts. We were glad to find them so looking up. The second, Silver Poland cock, was also a fine bird. The Houdans here present were not quite so good as usual, we fancied, though Mr. Dring sent two or three very good pens. *Geese* and *Turkeys* were very fine classes. It is some time since we saw better specimens of young birds at agricultural shows. *Ducks* were also very good, the *Aylesburs* especially. The ducklings were most promising, and the competition in *Aylesburs* unusually severe.

Pigeons were not large classes. We think they would pay for being better classified, and the Posters and Carriers more subdivided, but this Show seems to be great in making all the colours and varieties of the different breeds stand on their own merits, the one against the other, which in many cases is a most unwise proceeding. Mr. Yardley sent a very large collection of good birds, and took home a dozen prizes. The Carriers, Pouters, and Fantails were perhaps the best classes, though among the Toys, the winning Nuns, Jacobins, and Turbits were good specimens. We publish full list of awards below.

## NORTHALLERTON SHOW.

THE ninth annual meeting of this important agricultural association was held on the 17th inst., and the day being a most enjoyable one, the number of visitors was very large.

In the poultry and Pigeon department we find the Secretaries ever willing to convey suggestions to the Council, who are also ready to set upon them, and the consequence is that a show of little or no note a couple of years ago is now assuming most respectable proportions, and must ere long rank with the best of the Yorkshire summer exhibitions, which is saying not a little. The entries in all were near 350. The Show was held in the open field in the Society's own pens, which we suppose are to be replaced by some on a more modern principle.

Dorkings headed the list, the whole of the honours going to Waraby, the first-prize pen containing an extraordinary hen, but the cock being in bad feather lost the cup given by Mrs. Elliot for the best pen, which otherwise would have been awarded here. Game were poor except those noticed, which were all Brown Reds; the first and second, quite chickens, were very promising. Spanish were a very ragged lot of old birds, though the quality was very high. Cocks very good, the first to which the cup for the best pen in the Show was awarded being well-grown Buff chickens; the second splendid old Buffs, but sadly out of feather. Brahmas not so good as we expected. First a pen of chickens of fair quality, but the pullet a little light on the breast; second good old birds out of feather; very highly commended (Holmes), good chickens, but the cockerel far too young. Polish a grand class with almost every pen good. First Gold, and second White-crested Blacks. In Gold-spangled Hamburgs the first were a most correct pair of chickens, the cockerel one of the best out this season. In Silver-spangles the first and second were pretty good, but the two best pens (Robinson) were disqualified. In the first place a grand pen of chickens were thrown out on account of the cockerel's comb having been shaved, and was smooth and white on the serrating. When the class was judged, however, the first was placed on a splendid pen of old birds in apparent full feather, but on judging for the cup the cock was more thoroughly handled and examined, and was found to have had both sickle feathers inserted in the sockets of the old ones, showing that in this case at least it took two or three birds to make one good one. Gold-pencils a moderate lot, first young and second old; and in Silver-pencils the winners were mixed in age and pretty good. In the Variety class the first were nice Oréve-Cours, and second Malays. Game Bantams were a fair lot, the first chickens, and second old birds, and both Black Reds. Pen 108, very highly commended, were splendid Brown Reds, but did not match in leg. The Variety class was a good one, all being Black with one exception, where the second was awarded to a nice pair of Silver Sabrights.

Rouen Ducks very good in size, colour, and bill, as also the Aylesburys. Ducks, any other variety, were, first Black, and second White Decoys. Turkeys and Geese very good and large. The Selling class was very large, but there was nothing of note except the winners, which were Oréves, Light Brahmas and Game Bantams.

Pigeons were a good entry, but in some of the classes the birds were anything but good if the winners be excepted, this applying to Carriers, Jacobins, and Tumblers. In Pouters, first were Blue, and second White, and very good. The Fantails a fair lot; and Turbits, which were a large class, were very good, the first Blue, and second Yellow. Nuns were perfect as regards

the winners; and every pen of Magpies was well worthy of a place. In the Variety class an exquisite pair of plain-backed loes were first, and Red Dragons second, almost every other pen being noticed. In the Selling class Blue Turbits were first, and Trumpeters second.

Rabbits had two classes, and in bucks first went to a good Tortoiseshell 23 by 4½ inches, and second to a Fawn 23 by 4½, no other being of any note. In does a pretty fair Belgian Hare was first, and a Fawn-and-white Lop (too gay in colour), 21 by 4½, second; a few others being also noticed.

DONKEYS.—1, 2, and 3, J. White, Waraby. Ac, A. Jackson, Broughton; J. White.

GAMES.—1 and 2, W. Youngshusband, Darlington. Ac, W. Youngshusband; — Sanderson, Old Ormsby, G. Carter, Bedale. 4, Blackburn & Maynard, Northallerton.

## THE JACOBIN.

LIKE Mr. Huie I was astonished at the last Crystal Palace Show to hear for the first time that one of the qualities of the Jacobin was the rose, and when it was pointed out to me I at once said it was a defect instead of a property. I was told that that was what they were breeding for now, and the more perfect it was the better the bird. Whereupon meeting some old friends of mine, old men as well as true fanciers, I took them to see the new invention, and finding that it was as novel to them as myself I dismissed the matter from my mind altogether. Hence the reason I did not mention it in my last letter on the subject, but I now write to thank Mr. Huie for taking notice of the heresy. The Jacobins of the present day are too short in feather, and are much more of the Tumbler form than the old and true type. They were, as Mr. Huie describes them, long in flight and tall, otherwise it would have been impossible to have obtained that marvellous length of frill which they possessed, the feathers lapping over each other on the breasts of the birds instead of the wide space we see now-a-days, looking at them at the full front.

Another point I often see very deficient, and that is the colour of the thigh. Frequently there is white mixed with the ground colour, and it ought to be one firm solid tint, the same as the

wings, until it reaches the vent. But modern fanciers are not so particular as to feather as are many of the older fanciers, or else we should see less of the dingy reds and yellows, many of the latter almost mealies, and of the former strawberrys.

Where are the beautiful Blue Jacobins? One never sees them now—no, not with all the prizes that are offered for good birds, nor do we see those deep rich yellows. Where are they? Can no one be tempted to *breed up* again these fine old sorts, or are we really, as an excellent fancier over eighty years of age said to me, "Sir, where are the fanciers?—there are plenty of exhibitors." And so there are, and yet some very good fanciers are, I am glad to say, still taking a delight in breeding and keeping their birds; but I am sorry to find that in the majority of cases having obtained a pair of good birds they are sent about the country from show to show until they are worn out. No doubt there are good birds still in existence in the hands of private fanciers, who love their birds too well to send them about to shows and on long journeys, and possibly ere long we may see some of the true old sort of Jacobin, true in form, feather, and colour, perfect types of the breed. Higher prizes will not improve the breeds, nor do cups for the greatest number of prizes won by one person, as this is quite a mistake, and only leads to the borrowing of birds, even pairs being made up in such manner simply for the purpose of winning a few shillings, and not for the honour of having bred and reared the winners. When it comes to this we shall have better birds, and I am afraid not until then.—HARRISON WAIN.

### PROFIT AND EXPENSE OF REMOVING BEES.

A CORRESPONDENT, "C. F. F.," wishes to know "where the nearest heather is from Hinckley, Leicestershire, and what arrangements are generally made for placing hives on or near the moors, together with the expense. Would it pay to take half a dozen hives thirty or forty miles to the heather in the proper season? I am asking this as information for another year. What weight of honey would a super hold containing 200 square inches?" As the questions of "C. F. F.," touch a subject of interest to many readers, it may be well to answer them here instead of through the "Letter Box."

I cannot tell our friend how far Hinckley is from a good field of heather, but fancy he will easily ascertain this from some of his neighbours. I remember passing a considerable breadth of heather in Warwickshire some thirty years ago. I am better acquainted with the localities farther north, where heather abounds. There are magnificent seas of heather in Staffordshire, Derbyshire, Yorkshire, Cheshire, and the more northern counties. In the most southern counties of England—viz., Sussex, Surrey, Hampshire, and Devon, I believe heather in abundance may be found. Bagshot moors are within an easy distance of London bee-keepers. Nothing need be said of Ireland, Scotland, and Wales where heather superabounds. The Cheshire and Derbyshire moors are within fifteen miles of Manchester, and to these we are indebted for our heather honey.

As to arrangements and expense of placing hives on the moors, it may be well to confine my remarks on this point to my own experience. This year I took thirty-two hives only to the moors. In former years I took twice that number. I pay a greengrocer 4s. for taking a load of sixteen hives (that is 8d. per hive) to Manchester, a distance of five miles and a half. There the hives are taken from the cart and put into the luggage van of a passenger train, and carried up the Sheffield line of railway, nineteen miles, to Woodhead for 8d. per hive. The hives are placed within the company's line or outside of it under the care of the stationmaster. Crowden station is two miles nearer Manchester, and there I have placed hives every season for fourteen years. Both are excellent places for heather, but not better than many others on the Glossop (Duke of Norfolk's) moor. I prefer them for convenience, being able to place the hives within forty yards of the stations' platforms. No rent or charge is made by the stationmasters at Woodhead and Crowden. All that the bee-master can do is to remember that one good turn deserves another. The expense of carriage home from the moors is about 1d. or 2d. more per hive by the railway, as they are considerably heavier when they return. They go in lots of fifteen and sixteen, that number being as many as the greengrocer's cart and the guard's van will take at once. They return in lots of thirty hives, as I engage an empty van, called "a dummy," on purpose, fill it at the station, and have it attached to a returning passenger train from Sheffield. The thirty hives are met at Manchester by a lorry or plant van, which brings them to Sale. The expense of thirty-two hives in going from Sale to Woodhead and back, a distance of twenty-five miles, including carriage and all gratuities, is less this year than 50s., considerably less than 2s. per hive.

The cottagers on the skirts of moors in England and Scotland generally charge from 6d. to 1s. rent per hive, and are very pleased to earn money so easily. The bee-keepers in the neigh-

bourhood of Middleton, near Manchester, engage a cart to take their hives to the moors near Mossley and Greenfield, place and cover them, and bring them back at the end of the season at 2s. 6d. per hive. The cottagers there charge 6d. per hive only.

"Does it pay?" "Is it worth the trouble and expense to take bees so far in this uncertain climate?" I have found it profitable, and all the apirians I know who keep bees for profit find that there is, taking a run of years, much gained by taking bees to the moors. The most I have ever known a single hive gain on the heather was 70 lbs. This season many of the large hives or first swarms gathered and stored-up about 50 lbs. each in fifteen days. Thirty of my hives came home about 1000 lbs. heavier in all than they were when they went to the moors. In former years I have taken stronger hives to the moors than I did this year, but owing to the weather being so unfavourable in July for bees, they had to a lamentable extent ceased to breed. Their brood combs—indeed, all their combs, were nearly empty by the 14th of August when the weather became favourable for honey-gathering. The bees having but little brood to attend to and plenty of empty combs, very speedily gathered great stores of honey; really they poured it into their hives during the last fortnight of August.

I kept twelve hives at home this year, and during the heather season they have been kept alive with sugar. After July bees gather very little honey from clover, though the weather may be fine. Those who remove their bees to the moors have three chances or seasons of honey-gathering: first, the fruit trees; second, the clover; third, the heather. My profits for the last six or seven years have been mostly realised from the heather.

While I am pretty constantly advising the apirians of Great Britain to keep strong stocks, I humbly confess that I need lecturing on this point, for every season I have ample evidence that from strong stocks or early swarmers only great results are obtained. While some of the early swarmers and early swarms gathered 40 and 50 lbs. each, the later and weaker swarms would not gather more than 20 lbs. each, and the trouble and expense of removing and managing the one is as great as the other.

A super containing 200 square inches will I think, hold 7 or 8 lbs. of honeycomb. One of my swarms filled a super on the moors which weighed 28 lbs.

In stating the expenses of my bees above I have omitted my own railway fares, which are about 8s. 6d. a journey to and from the moors.—A. PATTINGAW.

### HONEY SEASON IN CHESHIRE.

At the beginning of the season I had only two hives of bees in 16-inch straw skeps of the Pettigrew pattern. The bees did very well on the fruit and sycamore blossom, and I drove a swarm from No. 1 hive on the 15th May, and one from No. 2 on the 29th May. I had a second swarm from No. 1 on the 28th May, and a second swarm from No. 2 on the 16th June. I drove out the bees from stock hive No. 1 on the 5th June, and from stock hive No. 2 on the 19th June. By this means I increased the number of my hives to six, all in new clean 16 or 18-inch skeps, having taken the honey from my two stock hives. During July the weather was wet, and occasionally I had to give my bees a few pounds of sugar to keep them from starving, but clover was plentiful and they did not require much feeding. I took my six hives to the moors on the 2nd August, all feeling light, although three of them were strong in bees and comb. The weather was good in August; and when I brought my hives home on the 8th September they weighed respectively 90 lbs., 88 lbs., 60 lbs., 52 lbs., 46 lbs., and 32 lbs., including hives and boards.

The following is the nett result of my honest harvest for the year—92 lbs. of run honey and 34 lbs. of honey in the comb; besides which I have sold two of my hives for £2 each, and I have two good stock hives which I am keeping for next year.

In taking the honey from my strong hives I joined the bees taken from them to those in the weaker hives, and by that means made the latter very strong in bees for next season's work. I feel sure that my success is to be attributed to the use of large straw hives, and taking the hives to the moors when the clover season was over, and giving the bees five or six weeks more of a season on the heather.—E. THORP, Sale, Cheshire.

### LIGURIAN BEES.

As a bee-keeper for the last twelve years may I reply to "A YOUNG APIARIAN," page 217? In the spring of 1870 I purchased from an importer six Ligurian queens, and introduced them to black stocks, and every year since have purchased a further supply. I have now ninety stocks of bees, black and Ligurian, in my apiary, and from careful observation I am convinced that the Ligurians are one-third the best; they swarm earlier, they breed later, and are more prolific. I have every year repeatedly

seen one-third more Ligurians go home from work in a given time than the blacks. I have such belief in their superiority that I intend to ligurianise the whole of my stocks this year.—J. H. HEDINGTON.

### FOUL BROOD.

FOUL brood may be found in many hives, and as it is destructive of all healthy action in them, bee-masters should be constantly on the watch for its existence. Three weeks after swarming and the month of September, when all healthy brood has been hatched, are the two seasons for thorough examinations of hives. If then some cells be found with lids on them strong suspicion should be excited. If the point of a slender of wood be pressed into these covered cells the foul brood or offensive matter will become apparent. It has recently been described as like the gravy of red meat in colour and appearance. Every hive containing foul brood should be condemned and not kept as stock. The bees should be united to other stocks or put into clean hives and feed.

The late Mr. Quinby was of opinion that the honey of hives infected with foul brood carried the infection to other hives if given to their bees. On this point we differ in opinion from him. We have had swarms naturally and artificially from hives containing foul brood, and though bees in swarming carry off as much honey as they can, we have never found them carry the disease to other hives. We have seen hives so extensively diseased with foul brood that the honey could not be taken from the combs separately by the hand of man. We have allowed the bees of other hives to clean the honey from the brood in such cases, but have never known the disease carried with the honey. Mr. Quinby was an able apiculturist and an independent thinker, but on this point I think he and others have failed to furnish proof in support of their opinions. The readers of this Journal will do well to examine their hives as soon as possible to find if foul brood is in them. If it exists at all now it will spread as soon as breeding commences. It is an incurable disease.—A. PATTISON.

### OUR LETTER BOX.

**SHOWING A DUBBED GAME COCKEREL (O. F. S.).**—A Game cock may be shown after he has been dubbed a fortnight, or even earlier. It is wonderful how soon they heal. A hackle feather should be laid on each cut; it stays the bleeding and helps to heal the wound. We often turn birds out that have been only dubbed four days, and but for the black marks that show the future doctor no one would know they had been operated upon. We have no doubt the lumping you mention proceeds from some injury, though it may not be perceptible; perhaps a thorn, perhaps a small piece of glass. Pass your thumb over the foot, and see if he shrinks. Handle the leg from the foot to the insertion of the thigh bone to see if there be any tender part. If there is nothing to be felt there is a sprain somewhere else, and he will get over it.

**FOWLS' LIVERS ULCERATED (Westcroft).**—The fowls you mention should be very strong. We do not think your feeding is good enough for hens that are laying and sitting. Insufficient or poor food always induces disease of the liver in poultry or game. That is the cause of the death of your birds. Rice is bad food. If you make up your mind to feed only once per day, it should be towards evening. In the morning a grass run afford three times as much food as it does in the evening. They should be induced to seek it by having nothing given to them. They have the day before them. If you feed just before they roost you then enable them to get through the longening nights without damage. We, however, advise you to feed night and morning, maize and barley mixed. An asphalt floor is bad, because it is unyielding to the feet of the birds, and because it affords no scratch. It causes disease of the feet and knees, and induces paralysis. Gravel or road grit or common earth mixed with some chalk are the best things.

**MR. BURNELL'S BUFF COCKER COOK (W. J. F.).**—Both stuns are correct, for there were two offers for the bird in question from different parties. Neither of them was accepted by the owner.

**THE CHIEF POINTS OF A GOLDFINCH (C. F. F.).**—The all-important point in a Goldfinch, as in all others of the feathered tribe, is condition of plumage, without which other points of perfection are almost entirely useless. A cock bird should be of good size for exhibition purposes, which is preferable to a small one, and shows off the following points to greater advantage:—Head, bright scarlet red, showing no white speck or mark on the throat; the back part of the head and near the back sides of the neck deep black; beak, large and pointed; breast, the centre white, with the sides of the breast pure brown; back rich brown; cheek and sides of neck white, the whiter the better, in fact distinctness of colour throughout is much to be considered. Larger covers well-marked with pure yellow; feathers close and in good bright condition; wings and tail and feet perfect; the thighs grayish; pinion feathers velvet black, with whitish tips, which are smallest in old birds; tail slightly forked and black, the two and sometimes the three outer feathers on each side having a white spot in the centre of the inner web. In some parts birds marked as last specified are termed "three by sixes," owing to having three feathers on each side of the tail spotted or mooned with white.

**AN AFFLICTED PARROT (Mrs. Mallory, Woodcote).**—From the remarks in your letter we fear there is faint hopes of your Parrot ultimately recovering. The affection in the throat and whistling and wheezing noise are very unfavourable symptoms. Very likely the apparent obstruction in the throat will become more evident, and a spasmodic fit may follow. If so, lay hold of the bird around the throat and immerse it in a warm bath, and after holding it in two or three minutes, syringe or squirt over the bird's neck a little brandy. You may administer a few drops of castor oil. If you have done so supply it with bread and milk as a general diet, and give a little ripe fruit. No meat. Water will not be required. Discontinue the Indian corn, more especially as the Parrot appears to suffer more after partaking of it. For healthy birds it is good sound food, but should be soaked before giving.

When the sun is shining at midday give the bird a shower bath, after which place the bird and cage before the fire, so that the Parrot may become warm. Let the bird have rest by keeping the cage covered. A little weak brandy would be better than strong, particularly when the bird appears to suffer after its food. The bird's filth is the cause of its ceasing to talk.

**GREENFLOWER LARVAE FROM RABBIT (P. M.).**—The larvae and stalks are good food for any animal that will eat them.

**BEES IN HOLLOW TREE (D. Green).**—As the hole or aperture in the tree leading to the cavity containing the bees and honey is so small (3/4 inches wide), the easiest way of securing the honey would be by killing the bees with powder or kerosene, and then placing a strong hive near the place, the bees of which would soon fetch the honey from the tree and store it up in their own hive. Every particle of honey would be removed with but little loss.

**BREEDING BEES (F. J.).**—By feeding your bees slowly, or at the rate of 1 lb. of sugar every two days, they will be kept in a state of excitement for weeks, and store up very little food. By giving every five 6 lbs. per day, the most of it will be stored up, the excitement in the hive, the cause of fighting and defence, will last but a short time, and the bees will speedily settle down to the quietness of winter life. If you do not wish to promote breeding and the consumption of food in your hives, the more rapidly they are fed the better in autumn.

**WASPS (F. W. H.).**—Without being certain that we are correct, we have always considered that wasps do not increase in size after emerging from the pupa state. There are wasps of various sizes in each nest; the females are the largest, and there are of them two sizes. These are produced later than the workers, and may have given rise to the opinion that wasps grow.

### REMARKS.

15th.—A most beautiful day, and the moonlight night equally fine.  
16th.—Very fine all day, but gradually clouding over towards night.  
17th.—Thunder from 1.35 to 2.5 A.M., heavy rain from 1.35 to 1.50, and morning; fine in the middle of the day, but dark and close in the evening and night.  
18th.—Misty till 8 A.M., then fine, but close and uncomfortable; cooler at night.  
19th.—Fine morning, but dull after 3 P.M., and rain about 6 P.M.  
20th.—Fine morning; showery from noon till 2 P.M., and fine afterwards.  
21st.—Misty and very dark all day; rain commenced about 7 P.M., and continued till nearly midnight, at times very heavy.  
The mean morning temperature rather higher than during the last few weeks, but the air damper. Very heavy rain on night of 21st.—G. J. SYMONS.

### COVENT GARDEN MARKET.—SEPTEMBER 22.

A heavy supply and trade quiet have prevented common goods being cleared as well as we could wish. Foreign produce remains the same as last week; but a large quantity of St. Michael Pines have just arrived, which will fetch low prices on account of the hot weather we have experienced lately. A better supply of Kent Cobs and Filberts this week at downward prices.

From observations taken near London during forty-three years, the average day temperature of the week is 53.2°; and its night temperature 42.7°.

## SOIL AND CLIMATE IN RELATION TO PRACTICE.

HERE must appear to on-lookers to be sometimes a very great difference in the theory and practice of two gardeners who are differently situated, and both of which are known to be fairly successful. The one seems to act altogether in an opposite direction to the other, and apparently to condemn almost everything the other proposes. This must be very enigmatical to those who have had no chance of experimenting under different

conditions in various parts of the country, for no one but the initiated can possibly believe that soil, climate, and the demands and resources of a place can have so much to do with moulding a man's practice as they really have. Reverse the positions of two men who seem to act in entirely opposite directions, and you would probably find in the course of a few years, if both had equal natural ability and both had been well schooled in the rudiments of horticulture, that each would materially alter his practice.

The gardener who has been educated in several places widely different from each other knows well that the same practice will never answer in two different places, and hence we find that the wider our practice extends the more we have to learn, and the less conceited are we. Young men who remain in their first place for several years, and find there is nothing more to learn there, are astonished when they go to a strange place and find things totally different, and that they have very much to learn. At first they are inclined to think it is not themselves in fault, it must be that those they have the misfortune to be placed under in their second situation cannot know much about the work, and they more than hint that the work was not done in that way at the Squire's or the Duke of So-and-so's. By degrees they find out that their new master's practice is equally successful as that of their former one, and from this moment begins their real education; they discover that gardening is not a mathematical science, and they put themselves on a new tack.

I was led into this train of thinking on reading of Mr. Luckhurst's system of applying heavy surface dressings of manure to fruit borders and to many of his growing crops, the results of which he has detailed in one or two papers lately; and now in the interesting notice of Oldlands by "A VISITOR" I read, "For fruits especially, in Mr. Luckhurst's estimation, it has quite superseded the practice of digging-in." Of course I cannot doubt for a moment the soundness of Mr. Luckhurst's practice, the results speak for themselves; but, for all that, I can assure your readers that I have no intention of adopting it here, and for this reason—that my soil is almost too heavy to be called a soil at all; it is clay, and such heavy clay too that if it lies a year or two unmoved it is almost impervious to air, and becomes, consequently, sour. To cover such a soil with manure and leave it on the surface would only make matters worse. Even the litter we are obliged to

put among the Strawberry plants to keep the fruit clean does some injury in this respect, and it is cleared off as early as possible; and in spring, too, quite in opposition to what would be sound practice on light and medium soils, we dig a little light manure in a full spit all over the Strawberry beds, and quite close to the plants, leaving the soil rather rough and hollow. For all this the plants never require water, and the crop of fruit is such as no light soil can produce. It will be seen by practical men that the little manure we dig-in is more for the purpose of aerating the soil than for stimulating the plants, and consequently light littery stuff, such as that from a spent hothed, is as good as anything for the purpose.

With regard to the Peach trees described by Mr. Luckhurst and "A VISITOR," I frankly own that if I had them I should be proud of them, and probably should not attempt any other system of training while they continued in health; but I have tried something similar here on two different occasions, and either from unskilful management or an unfavourable climate (I very naturally attribute it to the latter), the trees, after growing respectably a year or two, either died or grew very unsightly and invited removal. From past experience here I do not expect my Peach trees to last more than five or six years, and I mean to have what I can out of them in that time.

It will be seen from what I have written elsewhere that I am no advocate for cordons and miniature trees in general; but although I recommend what some people call the extension system with all trees where they can be so grown, for the fruit is always of better quality from a tree which is allowed to extend itself moderately, I do not blindly follow that system where it does not prove satisfactory. The principal reason it does not prove satisfactory here with the Peach is that the long growths do not become matured, and necessitate some method of pinching and shortening. I have adopted the plan described at page 197 for its simplicity.

I wonder if all gardeners have a bad soil and climate to deal with? There is a popular idea—it may be a popular error—that Sussex is not the worst county in England in which to grow fruit, but it does not seem to come up to Mr. Luckhurst's idea of a good climate. I must, however, say plainly that I think his magnificent trees point to something else besides skilful management.

I gave in my former notes the dates of picking the first fruits of the earliest sorts from the trees. Since then I have had Hunt's Tawny Nectarine, 28th of August; Grosse Mignonne Peach, 30th of August; Bellegarde, 3rd of September; Dr. Hogg and Stirling Castle Peaches, Violette Hâtive and Oldenburg Nectarines, 4th of September; Downton and Elruge Nectarines, 7th of September; Barrington, Prince of Wales, and others are not fully grown yet (September 20th). Most of the fruits would be a week or more after the above dates before they were fit for table. I gather them when if taken hold of with the whole hand they feel slightly elastic. Stirling Castle is in appearance very much like Belle-

garde, and perhaps slightly inferior to that noble Peach. We do not want both kinds.—WILLIAM TAYLOR.

### A TRIP TO LONDON.—No. 1.

I THINK it was London who said that a gardener ought to visit the metropolis at least once a year, and he was undoubtedly right, even in his day, when the world, or rather the people in it, went at a more sluggish pace than in our own brisk time; and much more so now that cheap and rapid travelling is so general.

An interchange of ideas, a discussion of critical points of culture, of success or failure, its cause or remedy, and other matters of common interest, cannot fail to be beneficial. To study different features in gardenesque scenery, such as combination of colour as in flower beds, of forms stately, symmetrical, quaint, or grotesque, as in shrubs and tropical and alpine plants; to see new plants and such other objects of interest as new garden structures and implements;—these are some of the objects which we blue aprons have then in view, and not mere pleasure in the common acceptance of the word; and I think it may fairly be claimed that an outing with such aims and ends points to praiseworthy results—self-improvement of the individual, by which his services will become more valuable, and his future efforts tend more directly to his employer's advantage, as well as a relaxation and break in the daily routine of life's duties and cares. The best time for such an excursion is undoubtedly the autumn, and if possible during the holding of one of the large fruit shows, so as to meet as many "kindred spirits" as possible. Having lately enjoyed such a trip, it is purposed in this and one or two more communications to give a sketch of what was seen, and to call attention to such matters as were noteworthy.

In the journey to and around London two things impressed me as affording evidence of a general growth in culture and refinement. The first were the numerous bouquets in the hands of travellers and the manner in which they were made; a neat rounded globular outline and moderate size was the common characteristic, differing so agreeably from those high flat-backed masses, with a backing of "Lad's Love" and Rosemary of our youth. It was amusing to see how they were cherished; one was actually carried with the stalks inserted in a glass of water, and another in which the flowers were closely packed was, as the owner assured me, to be taken to pieces and utilised for dressing "all the vases at home." A bright young maiden this, returning to her town home from a seaside holiday, bearing back a bit of country brightness and freshness to gladden the heart of the grey-bearded father who was awaiting her return at the station.

The second point of attraction was found in the many excellent flower gardens at railway stations, suburban villas, aye, and even fronting many a suburban cottage—neat and trim and bright, many of them containing really exquisite little bits of carpet bedding, denoting much attention and care, and presenting a charming contrast to the few straggling dust-laden plants in adjoining plots. These were all particularly interesting and attractive, not only for their intrinsic worth and beauty, but as affording evidence of what an important educational work is being done by the superior order of gardening now practised in our large public parks and gardens.

The first place of note which I visited was the Alexandra Palace, and I must confess to a feeling of considerable disappointment with many things which came under my notice. In this instance, as is frequently the case, I had probably anticipated a more finished scene than the reality proved to be—grounds highly dressed, elaborate terraces with that massive balustrading which imparts dignity, and that accompaniment of vases and statuary which add elegance and grace; all this will no doubt be gradually added with other necessary features to impart an air of greater warmth and fulness to the grounds.

The Fruit Show which was held at the time of my visit, although not answering to its somewhat ambitious title of "International," was undoubtedly a fine one in many respects, losing much in effect, however, from the brilliant, almost gaudy decorations of the magnificent hall in which it was held. The eye, while yielding to the attraction of the fruit, involuntarily sought for some foil, some repose to bring out its full charms. The cool fresh greenery of Palms and Ferns dispersed among the dishes, and a slight ornamental awning suspended over the tables would, I think, have effected this admirably, and imparted a perfect finish to the sumptuous display. There exists a wide difference of opinion in all such

matters of taste. The crowded state of the Show, especially on the last day, showed clearly how much the Exhibition was appreciated.

Flower beds are not numerous here, the principal display being in an interior court, which was very bright with colour. The walls of this court are being covered with purple Clematis, with which I would suggest an admixture of Camellias—always ornamental in their glossy green foliage, and of surpassing beauty when in flower. These would answer well here, as would many choice semi-hardy climbers. Most of the trees and shrubs are still too small to produce much effect. Araucarias are evidently not flourishing, and judging from my own experience I should say decidedly that plants of 2 or 3 feet high would answer much better than large specimens in such an elevated and exposed situation. It is only under very favourable circumstances that large specimen Conifers should be transplanted, for during the four or five years which they require to become thoroughly established younger plants will rush past them, taking and keeping the lead.

Let me give an example, for this is a matter of the highest importance. A dozen Thuja Lobbi, nice specimens, 8 feet high, and with compact balls of soil about the roots, were planted with all due care about four years ago. During the same season I happened to purchase two hundred young plants of this same Thuja 2 to 3 feet high, and standing in close nursery rows; they were put in the home nursery and transplanted year by year to permanent stations as required. At the present time some of them are quite 12 feet high, while none of the first-planted specimens are more than 10 or 11 feet. The younger plants have taken the lead, and they will keep it. The growth of one of them last season actually exceeded 4 feet. Other examples of Wellingtonia, Araucaria, Cedrus, &c., might be cited if necessary.

The collection of Agaves and Cacti exhibited in a glass house apart from the Palace is most interesting, and would be even more so if the bare staging upon which the plants are arranged were replaced by masses of rock or turf covered with mosses and Ferns or choice trailing plants, among which the quaint succulent forms could be plunged and arranged to the greatest advantage, gaining immensely in appearance when so managed, and losing all of the present harsh effect.—EDWARD LUCKHURST.

### THE CARNATION.

There are three modes by which the Carnation can be increased—namely, by seed, by layers, and by pipings. The first is practised with a view of obtaining new and improved varieties, and the other modes to propagate them when obtained. The seed should be saved only from double-flowering varieties, or those that are nearly so, for a perfectly double flower cannot produce seed. The seed pods will be shorter and the seeds fewer from such flowers than from single flowers: hence it is very valuable. Gather it as soon as it is ripe, and keep it dry and cool through the winter. Sow in boxes in March placed under glass, or in a warm border in April. Transplant the seedlings 3 inches apart on a bed enriched with leaf mould or well-decayed hotbed manure as soon as they are large enough, and let them remain on the bed through the succeeding summer and winter, and they will all flower the following season. Mark such as are good, name them, and layer them in the way I shall describe presently.

CHARACTERISTICS.—The following characteristics constitute a good flower:—First, the stem of the flower should be strong and straight, not less than 30 inches nor more than 45 inches in height, and able to support the weight of the flower without hanging down. The flower should at least be 3 inches in diameter. Secondly, the petals should be long, broad, and stiff, easy to expand and make free flowers; the lower or outer circle of petals, commonly called the guard petals, should be particularly substantial; they should rise perpendicularly about half an inch above the calyx, and then turn off gracefully in a horizontal direction, supporting the interior petals, which should decrease gradually in size as they approach the centre, and with them the centre should be well filled. All the petals should be regularly disposed, and lie over each other in such a manner; they should be nearly flat, or with only a small degree of inflection at the broad end; their edges should be perfectly entire without notch, fringe, or indenture; the calyx should be at least an inch in length, sufficiently strong at the top to keep the basis of the petals in a close and circular body, and the middle of the flower should

not rise too high above the other part. Thirdly, the colour should be bright and equally marked all over, the flower perfectly distinct, the stripes regular, and the outline of the flower should be round and perfectly smooth.

**SOIL.**—This is a very important matter, for without good soil it is in vain to expect good show flowers. Old garden soil is not at all suitable, but fresh virgin loam is absolutely necessary. It must be looked for in an upland pasture, and the upper stratum, about 8 inches thick, is the best. Add to this about one-fourth of two-year-old well-decomposed cow dung and the same quantity of leaf mould. A small quantity of finely-sifted old lime rubbish will be found useful to mix with it; this keeps the soil sweet and open. This compost previously to being used should be put into a place where it will gradually become moderately dry.

Carnations, Picotees, and Pinks, in order to produce perfect flowers, must be young plants raised every year. The mode of layering a Carnation is well known to every gardener, but I may say that I do not approve of the old method of shortening the leaves, for I consider the cutting-off a portion of the leaf is injurious, and hinders the layer from rooting so soon as it otherwise would if the leaves were left entire. I have proved this repeatedly. Trim off the lower leaves on every shoot before commencing to layer, because when a layer is tongued it is easily broken off. The layers when prepared should always be pegged into fresh soil and have a slight watering, with further supplies if the weather is dry. They will be rooted in about a month or six weeks.

Propagation may also be effected by pipings where there is the convenience of a gentle hotbed; it is, however, not so safe as layering. When there are more shoots than can be layered, and it is desired to propagate largely, take them off and cut off the lowest pair of leaves, and pass the knife just through the joint. Prepare a pot by draining and filling it with the proper compost up to within an inch of the top, and complete with silver sand; water it gently to make it firm, and then insert the pipings all round close to the pot's sides, placing them in a gentle hotbed, and shading from the sun.

—J. H., *Gardener to Lady G. Legges.*

#### ESTIMATE OF NEW AND RECENT ROSES.

**BARONNE DE BONSETTIN** is splendid, a fine erect grower; the flower very thick in petal, and if grown with care—that is to say, shaded in sunny weather—is almost unequalled amongst dark Roses. **Captaine Lamure** is a Rose for high-class growers. It requires heavy manuring and a little guano, when it produces blooms most pleasing and distinct and of very fine form. **Dupuy-Jamain** is a fine free-flowering garden Rose, an improvement on **Madame Crapelet**. **Etienne Levet** is the best of the rose colours, being, in fact, a carmine **Charles Lefebvre**, and cannot be too highly recommended. **François Michelon** is good. **Louis Van Houtte** is the finest (take it all round) dark Rose we have; it requires high culture and close pruning. **President Thiers**, a crimson **Victor Verdier**, is very bright and pleasing, but not full enough. **Annie Laxton** is not particularly good, but might be bought if the grower has plenty of room. **Bessie Johnson** is very middling.

**Madame Lacharme** is a bad Rose. The great want is still a good white Rose, and growers are tempted to buy all sorts of rubbish in the hope of something turning out good. This Rose has caused great disappointment. **Mlle. Marie Cointet** is very pretty, in the way of **Marguerite de St. Amand**; it is of lovely shape, but rather small. **S. B. Hole** is a splendid Rose. This, **Louis V. Houtte**, and **Xavier Olibo** vie with one another. **S. Reynolds Hole** is the best grower and thickest in the petal. It would, I should say, make a good climber, as it seems to throw long shoots before blooming. It is very fine, and must be in every collection. **The Shah** is a light red Duke of Edinburgh, very bright, but it struck me as being rather thin.

**Wilson Saunders** is truly grand, being a scarlet **Charles Lefebvre**. It looks like a cross between that variety and **Lord Clyde**. It is a splendid grower, and one of the finest Roses yet produced. **Caroline Kuster** is good, in the way of **Céline Forestier**. **Belle Lyonnaise**, a lemon-coloured **Gloire de Dijon**, should be in every collection; also **Madame Berard**, of the same class, but inclining more towards **Madame Faloot**. **Cheshunt Hybrid**, a very free-blooming red Tea, is a novelty and very pleasing. **Madame Denis** is good. **Marie Van Houtte** is one of the most beautiful Teas we have. **Catherine Mermet** is also one of the finest Roses lately brought out.

The following list may be useful to some of your readers, being the cream of the Rose world. All are first-rate. **Alfred Colomb**, **Baronne de Bonsettin**, **Baroness Rothschild**, **Camille Bernardin**, **Captaine Lamure**, **Charles Lefebvre**, **Countess of Oxford**, **Dupuy-Jamain**, **Dr. Andry**, **Duke of Edinburgh**, **Edward Morren**, **Etienne Levet**, **François Louvat**, **François Michelon**, **Général Jacqueminot**, **Horace Vernet**, **John Hopper**, **La France**, **Leopold I.**, **Lord Clyde**, **Louis V. Houtte**, **Madame C. Joigneaux**, **Madame H. Jamain**, **Madame Noman**, **Madame Vidot**, **Mlle. E. Verdier**; **Marie Bady**, **Marie Baumann**, and **Sénateur Vaisse**, the three best light red Roses; **Marquise de Castellane**, **Olivier Delhomme**, **Paul Neron**, **Pierre Notting**, **Président Thiers**, **Prince O. de Rohan**, **Vicomte Vigier**, **Victor Verdier**, **Xavier Olibo**, **Annie Laxton**, **Marie Cointet**, **Reynolds Hole**, **The Shah**, **Wilson Saunders**.

Tea Roses depend so much on situation and the care and capability of the grower, that I only add a short list. All are tolerably hardy, but Tea Roses require protection in the winter. They do best either on the Briar or as pot Roses. **Céline Forestier**, **Maréchal Niel** (south wall), **Alba Roses**, **Belle Lyonnaise**, **Catherine Mermet**, **Devoniensis** and **Climbing Devoniensis**, **Gloire de Dijon**, **Madame Berard**, **Madame Bravy**, **Madame Denis**, **Madame Faloot**, **Madame Margottin**, **Madame Willermoz**, **Marie Van Houtte**, **Niphetos**, **President**, **Bubens**, **Souvenir d'Elise**, and **Souvenir d'un Ami**. There are several others worth growing, but they are rather the rich man's fancy. Any grower who will buy the above list, and take care of them, need trouble his head about nothing else.—**AN OLD ROSE-GROWER.**

#### AN OLD GARDENER'S ADVICE TO YOUNG MEN.

HAVING been forty years a gardener, and during that time associating with men of every class, I will here state that I have never known a wise, respectable, able gardener fail to rise to a respectable position, or fail to gain the respect of his employers and neighbours. Merits, like murder, will out. Great talents and ability cannot be hid. Popularity is almost always the reward of humble well-directed efforts and good conduct. A passion to learn and a determination to let nothing else come before a knowledge of gardening, are prime qualifications in beginners.

Education is necessary to success. We know very well that men can dig and plant Cabbages, make Vine borders and grow Grapes, without an "Education Act" or much book culture; but still, more education would help them in many ways, and make them more agreeable and eligible servants. Some twenty-five years ago a young man came under me as second gardener. His address was not very good. He was urged to study "Cobbett's Grammar." He obtained a copy of this work, and during the winter nights he read it by the stovehole fire, for he had no better. Before he finished his career as a journeyman he had sent some creditable contributions to the horticultural press. He now holds one of the highest and most lucrative situations that can be found in England. His own industry and respectability have raised him to the aristocracy of gardening.

Let me urge all young gardeners to spend the long evenings of winter in the pursuit of education and a thorough knowledge of the science of gardening. A single winter of study properly directed will raise young men high above their fellow workmen who spend their evenings in gossip and folly. Gardeners have so much to learn that they have no time for frivolity, and young men in commencing a career of gardening should make themselves acquainted with the thoughts of our best men who have written, and those who still write, on the practice and theory of gardening, natural philosophy, vegetable physiology, heat, light, chemistry, &c. Alphabets and catechisms on these subjects can be bought for a few pence. Strange it is that so many gardeners are content to travel at an easy pace along the road to mediocrity. Let young men remember that real, good, able, and accomplished gardeners are scarce. If a situation worth 20s. or 24s. a week becomes vacant, how many applicants there are for it! but if one at £100 or £120 a year presents itself, how few dare venture to apply for it! It is a great advantage to a man to possess cultured manners. Such manners never disqualify men of common sense for the wear and tear of rough work, and I have ever found young men of good manners and education rise faster and higher than those without them.

In taking situations gardeners should resolve to serve their

employers to the uttermost of their ability. To be good servants in every sense is the shortest road to gain the confidence and admiration of employers. To do right is the way to be happy. No one need fear that his virtues will not be found out or appreciated. Employers are well able to estimate a servant's character and worth. Taet, temper, and a disposition to serve are estimable qualities. With these and even a moderate share of ability gardeners will not fail to satisfy their employers, who seldom complain without occasion, and often abstain from complaining when there is occasion for it. If a gentleman should see anything wrong, why should he not mention it? And if he does mention it, why should the gardener unwisely retaliate by the use of immoderate language? Calm reason is always more effective than extravagant passion.

In the duties of life mistakes are often made, and, what is worse, are attempted to be hidden. The very confession of a mistake made in a transparent manner is an honourable trait in any man's character; and he who has the courage, prompted by a sense of right, to frankly admit an error is sure to win confidence, and in the end success. Be careful in forming friendships and social connections. In this matter much caution is needed, as an improper connection, or a connection formed at an improper time, is almost more than anything else calculated to mar the prospects of a man whose professional attainments and diligence would otherwise eventually secure him an honourable position in life.—A. PATTICREW.

### GROWING LARGE STRAWBERRIES.

My reply to a correspondent on this matter is that, in order to grow anything large, whether Strawberries, Grapes, or Pumpkins, the stock must be had from a vigorous strain to begin with. That is a point of the first importance, and one that is not so fully recognised as, with advantage, it might be. The next condition is, that to produce extraordinary specimens of a given fruit the soil and locality must be naturally suited for the growth of that fruit, and to this must be added the best assistance that art can give.

The Strawberries alluded to were the produce of one-year-old plants. Early runners were taken from the plants of exceptional vigour, and layered in pots in May; these were potted into 5-inch pots in June, and generously treated for forcing. They were so fine that a portion were repotted into 8-inch pots on August 1st, and were well tended. They were eventually planted out in strong rich soil 3 feet deep, and regularly watered with sewage. The fruit was thinned-out, and the crop was remarkably fine.

Early runners layered in pots and generously cultivated invariably produce larger fruit the first season than is produced from two-year-old plants. The fruit from one-year plants is, however, not so numerous, and the gross weight of the crop may not be so great as the crop of the second year.—F. G.

### HALF AN HOUR AT CYFARTHFA CASTLE.

CYFARTHFA CASTLE, the seat of R. T. Crawshaw, Esq., is within a few minutes' walk of the centre of Merthyr Tydvil, overlooking one of the largest iron works in South Wales, where the air is black with soot and smoke by day, and by night of a continuous red glare from the flames of its multitude of forge chimneys; yet here amidst so much that is detrimental to fruit-growing Grapes are grown by the ton. This is no exaggeration, for we found in one house upwards of seven hundred bunches of Canon Hall Muscat, grand in bunch and berry, and of that rich golden yellow that speaks truthfully of high flavour. If we only put them down at 2 lbs. each, though the greater part would be double that weight, we would have in this house alone more than half a ton.

In another house Gros Guillaume at once struck the eye, with its leviathan bunches; not one here and another there, but all the way up the rods and all over the end of the house. There are twelve Vines, I think, of it; these bunches would weigh 5 lbs. on an average, and only require a few days' more sun to finish them off perfectly. Since then (the first week in September) we have had beautiful weather here in the north; in fact, September has been the only fine summer month we have had. In another house Madresfield Court was equally fine, but the greater part was cut. Black Hamburg was all cut, with the exception of a few odd bunches, which just showed what they had been—beautifully bloomed, hammered, and coloured.

In a span-roofed Fig house the Figs are planted out in a

centre bed, and grown in gigantic bushes 9 or 10 feet high by as much through; these are ripening their second crop. On each side of this house, the pots standing on a narrow stage, were pot Vines trained over the pathway, one side containing those for next year's fruiting, and the others in fruit, each Vine carrying from 16 lbs. to 20 lbs. of Grapes. Eight bunches were the rule, and a regular rule it was, for there was little to choose in any of them, and as black as they could be for a thick covering of bloom. The chief variety was Alcantara, and, judging from results, there is no better one for pot culture. In a smallinery we passed through was a rod of Duke of Buccleuch, which did not at all look promising, and was thought little of at Cyfarthfa.

Pines are grown very extensively, there being upwards of three thousand plants in various stages of growth, a hundred ripe Pine Apples being required for every Christmas. One pit upward of 100 feet long was filled with odd plants which threw up between the main lots here, and my guide said, "We can cut a Pine any day of the year." They certainly looked like it, for there were Pines in all stages of fruiting from showing to ripe.

Stone fruit was nearly all gathered, just a few late Peaches and Nectarines only being left, but the foliage and wood looked quite able to rank as high as the Grapes in their season. It is, however, impossible to do justice to all in the short time that I had to look round this little town of glass structures.

There are eleven vineries, some of them very large, four Pine stoves, nine succession Pine pits, Fig house, three large Peach houses, two Peach cases 300 feet each, Apricot cases same length, and Melon pits.

But fruit is not all that is grown at Cyfarthfa, for at a little distance from the fruit houses, nearer the Castle were the plant houses, five in number, with pits hot and cold. The plant houses are roomy span-roof structures. The intermediate house is very lofty and large, containing tree Ferns, Palms, &c., one very fine *Latania borbonica* being as much as four men could move. In the stove are very large plants of *Crotons variegatus* and *angustifolius* 8 feet through and as much in height, *Alcacia macrorrhiza variegata* some 12 inches round the stem and the foliage large and beautifully variegated, *Bougainvillea glabra* bract stems 18 inches long, *Allamanda* and *Stephanotis* in equally fine condition; but I was a little too late to see this department at its best, the plants having returned from the last show of the season about a fortnight before. If Mr. Crawshaw should allow them to extend their showing radius we shall hear more of Cyfarthfa, its fruit and plants. In the New Holland house was *Erica Massoni* major in rude health and full of flower, and a pair of very fine *Yuccas*. But it struck me the large specimen *Erica*, &c., were old, and their places will be better filled in a year or two by the younger specimens on the side shelves.

But to do justice to Cyfarthfa would require both more time and a better pen than mine. However, a slight idea will have been given of the good things to be found in this out-of-the-way yet well-managed place.—T. W.

### BEES AND PEACHES.

WHEN a few weeks ago I saw it stated in the Journal that bees devoured Peaches I smiled incredulously, and said to myself "That is clearly a mistake, and you must look elsewhere for the robbers." When I state that for thirty years I have been a Peach-grower in places abounding with bees, and that I have never seen a Peach touched by them, you will, I trust, admit that I had reason on the side of my mistrust; but, alas! the awakening.

In the beginning of this year I went to a new situation, where Peaches had not hitherto been much cultivated. Peach-growing is one of my specialities, and I had a beautiful crop, of which I was very proud. One day a swarm of bees alighted in my garden. I made inquiries but failed to find an owner; so, having hived them, I kept them. I am sorry to say they have turned and stung the hand which saved them, and that, too, in its most vulnerable part. Last week I found that my prized crop of Peaches was ruined, and I had to take them off for preserving, or whatever else use could be made of the halves which were left. They were literally worried, and as I swept the bees off they fell to the ground helpless, completely surfeited, and unable to fly from the place. The destruction was little less complete than the destruction I afterwards made of the bees, and I guarantee that it is the last hive which will find a resting-place in my garden. I

send you this my experience in the hope that it may prevent others being the victims of their own overweening confidence, as I have been.—J. R. R.

[The bees were starving owing to the bad honey season. Had they been fed with a few pounds of sugar and water they would not have attacked the fruit.—Eds.]

### ROSES.

A LADY after visiting Mr. Cooling's Rose nursery states, "The best new Roses I have seen are Captain Christy, Etienne Levet, Louis Van Houtte, Maxime de la Rochetiere, Claude Levet, Marquise de Castellane, Marquise de Mortemart, and Marie Van Houtte (Tee)." She is an excellent judge, and lived here at Okeford Fitzpaine some years. The selection is very good. Marquise de Mortemart is lovely, but a weak grower. Marie Van Houtte I do not possess. All the rest are here and deserve the lady's praise. These are good new Roses and have done well—St. George, Souvenir de John Gould Veitch, John Harrison, and Theodore Buchetet; these are all high-coloured Roses and of great excellence in my judgment. These are excellent garden Roses—namely, Pierre Seletzsky and Hortense Mignard. Olga Mariz is a pretty white Rose in the way of Baronne de Maynard, but it is not so efflorescent nor so perpetual a bloomer. The Countess of Oxford is fine, and may be added to those named by the lady. The Roses here have done well. Since I have been a rosarian I never had them finer than they were here about June 10th.

The metropolitan shows are too late for any but possessors of large stocks of Roses or persons who bud largely. A good working rosarian, of whom I believe there are but few, ought to have his Roses in full bloom by June 10th. By ten or fifteen days later the centre buds should be mainly out and gone. The corollary buds are of no use for exhibition.—W. F. BANCROFT, Okeford Fitzpaine, Dorset.

### PACKING FRUIT AND CUT FLOWERS.

THERE are few gardens where some packing is not occasionally done, and in numerous instances it occurs so frequently as to be a rather formidable affair, consuming a good deal of time and material: it is important, therefore, that the best way of doing the work should be clearly understood. It is undoubtedly a simple matter, and yet it must be granted that it is one in which it is most desirable to excel; and I hope it will not be considered egotistical on my part if I state that quite as much pleasure has been felt upon being informed of the satisfactory condition of such soft fruits as ripe Peaches and Nectarines after a journey of eight hundred miles as in winning a well-contested prize at a flower show.

Fruit is packed in a variety of ways. Grapes, for example, are frequently sent considerable distances in perfect safety without the use of any special packing materials, the bunches being laid together as closely as possible with a little wadding at top and bottom. Attempts are also made to preserve the bloom by laying the bunches in open boxes and baskets, which are made to fit into other boxes. But it is neither a very successful nor safe plan; much rubbing is inevitable from the vibration of the train, and there is great risk of the Grapes being thrown out of the interior boxes and smashed in transit.

The plan which has proved perfectly successful, and which is now invariably followed whenever fruit is sent by rail, is to wrap each bunch of Grapes or fruit of other kinds in soft tissue paper, surrounding it with a slight padding of sweet bran as the fruit is placed side by side in a box. The paper is put upon the fruit in plain folds, and not twisted into hard corners, which may press into the next fruit and spoil it. Much care is taken to have each fruit thoroughly enveloped in bran, which is also settled into as compact a mass as possible by slightly jarring each box upon the packing bench after the top layer is put in, and when it is quite full a sheet of paper is put upon the bran and the hinged lid closed by hooks and eyelets of copper wire, and securely corded.

If this excellent old method is only done correctly all risk of failure is avoided. I have therefore entered minutely into details in order to assist those who, like me, have had failures, and which they are, of course, most desirous to remedy in future.

Cut flowers should be packed in a perfectly dry condition, and whatever packing materials are used should also be dry. Considerable quantities are sent in boxes by rail to distances varying from fifty to nearly three hundred miles in the follow-

ing manner with perfect success:—The bottom and sides of the box is lined with spray and Fern fronds; upon that at the bottom is placed a compact layer of buds and such flowers as will not suffer from a little pressure; then comes another layer with the more delicate flowers enveloped singly in a thin piece of wadding, all packed closely. This is followed by a sheet of silver paper, upon which a third and last layer of padded flowers is placed. A thin sheet of soft wadding is placed upon the top, and the lid fastened in the same manner as the fruit boxes.—EDWARD LUCKHURST.

### DIONÆA MUSCIPULA.

CARNIVOROUS plants have latterly received more than an ordinary share of attention. They are curiosities of the vegetable world, and have been the subjects of considerable research

Fig. 65.—*Dionæa muscipula*.

by botanists and philosophers. They are undoubtedly interesting, and some of them are highly attractive. They are also of comparatively easy culture, and anyone possessing a greenhouse may, with a little care, succeed in growing *Dionæa muscipula*. It is a native of Carolina, North America, where it grows in marshes or bogs. The soil best suited for it is sandy peat, with a little finely-chopped sphagnum moss. After being put into small pots a slight covering of live moss should be laid on the surface. They should be then placed on a shelf in an ordinary greenhouse exposed to the full force of the sun. As they require a good deal of water, a layer of moss should be placed on the shelf and the pots slightly plunged in it, which is preferable to placing them in flats of water; as in this manner the soil is not so apt to sour. When the leaves begin to decay withhold the water, but never let them dry-up entirely.

The *Dionæa* is propagated by seed, which it produces readily

if when in flower the pollen is slightly rubbed on the stigma with a small brush. Raising from seed is a slow process, but a very interesting one. The seedlings come up quite freely, but they are a long time before they attain any size. In the youngest state, however, they are quite as sensitive as the old plants.

As to their peculiarities. If a fly or piece of meat is put on the leaf it closes on it, and does not open until it is thoroughly digested, which for an ordinary fly takes eight days; in the case of the meat, when the leaf opens there is not a particle left behind; but if a piece of wood or any hard substance be put in, the leaf closes, but next morning it will be found wide open again. I have been feeding a number of them, but I cannot say that they are much the better for it as yet; however, it is just possible it may make them stronger next year.—R. L.

### INTERNATIONAL POTATO EXHIBITION, ALEXANDRA PALACE.—SEPTEMBER 29TH.

CONSIDERING the importance of the Potato as a staple article of food, it is not surprising that a fair share of encouragement should be given for the best examples of culture. At all horticultural exhibitions the section devoted to Potatoes invariably secures more than an ordinary share of public attention, and which fully warranted the institution of a special exhibition of the tuber. The season has generally been favourable to the growth of the Potato, and the disease has been much less virulent than in some previous years, therefore it was only natural to expect that a good response would be made for the liberal prizes offered on this occasion.

The object of the Exhibition is a laudable one, it being, as the prospectus informs us, established for the encouragement of the best methods of Potato culture, and the introduction and diffusion of improved varieties. The Exhibition being under the distinguished patronage of city dignitaries, and having an Executive Committee of singularly practical men, with a hard-working Secretary, at once secured public confidence, and the gathering was anticipated with a considerable amount of interest throughout the country. The schedule was divided into fourteen classes, and so arranged that the best varieties, home and foreign, should be brought into competition, and their relative merits be judged by comparison. Besides the prizes immediately offered by the promoters, the Alexandra Palace Company liberally subscribed £20 in four awards in addition to a silver cup value £10 to the winner of the first prize. Messrs. Sutton & Sons, Reading, offered prizes amounting to £10 10s. including a silver cup. Messrs. James Carter & Co., Holborn, offered a like amount and cup for six English and six American varieties; and Messrs. Hooper & Co., Covent Garden, offered prizes of similar value for American varieties. Messrs. Bliss and Sons, New York, also provided good prizes for three new American varieties, and Mr. John Coutts, James Street, Covent Garden, for three English seedling varieties.

The Exhibition was held in the Concert Hall, the dishes being arranged on five long tables of convenient height, and the display was a great and imposing one. It was no easy matter to judge so many collections of nearly equal merit. Owing to this, and the system adopted, the awards were not made until long after the admission of the public, and the usual crowding and impatience resulted.

For prizes offered by the Alexandra Palace Company for twenty-four varieties of nine tubers each there were sixteen competitors. Mr. R. Dean, Ealing, secured the first prize and ten-guinea cup with a collection of high quality. Some of the tubers were fully large, but all were excellent examples of their kinds. The most handsome dishes were those of the varieties of Mr. Fenn—viz., Onwards, Rector of Woodstock, Early Market, and International Kidney, very fine; the remainder were American and staple English sorts. Mr. Pink, Lees Court, was second; Mr. Jacob, Petworth, third; and Messrs. Cox Brothers, Gosberton, fourth.

For twelve varieties (nineteen competitors) Mr. Fenn secured the first place with an admirable collection, smooth and of a correct size for table use; they were varieties of his own raising, and as productions of one man probably unequalled. Second Mr. Pink, gardener to Lord Sondes; third Mr. R. Farquhar, Fyvie Castle; fourth Mr. Miles, Wycombe Abbey. For six varieties (twenty-four competitors) Mr. Porter, Old Meldrum, N.B., won the first place with a beautiful collection, Excelsior and Snowdrop being perfect dishes; Mr. Bates, Kingsbury, had the second place; and Mr. McKinlay third. For six varieties (kidney-shaped) there were thirteen competitors. These collections were very superior. The first prize was secured by Mr. Denyer, Beckenham, for admirable dishes; second honours going to Mr. Woods, Clipstone Park, Mansfield; and third to Mr. R. Dean. For six varieties (Round) were nine competitors. The produce in this class was not of high merit. A second prize was awarded to Mr. Woods, Clipstone Park; and third to Mr. Fin-

lay, Wroxton Abbey. The first prize appeared to have been withheld.

For the best dish of nine tubers of any White Round variety thirty-five competed. Mr. W. Porter, King Street, Old Meldrum, N.B., secured the first place with a grand dish of Excelsior, Mr. Potts being second, and Mr. Lye, gardener, Clyffe Hall, third; an extra prize being awarded to Mr. Bennett, Enville, Stourbridge, for an excellent dish of Schoolmaster. For the best dish of any coloured variety thirty-one competed. The first prize going to Mr. Potts, gardener to Viscount Gage, Fife Park, for Vermont Beauty, very large; second, Mr. Sexton, Thornington Hall, Ipswich, for Red-skin Snowball; and third, Mr. Hudson, Vandyke Court, Pershore, for "Princess of Lorne;" all too large. For the best dish of White Kidney Potatoes thirty-one competed. Mr. W. Smith, Petworth, was placed first for handsome unnamed tubers; Mr. Miller, gardens, North Down, Margate, being second; Mr. W. Finlay, Wroxton Abbey, third; an extra prize being awarded to Mr. Montgomery, Sillington Manor. These dishes contained tubers of immense size, and not at all suitable for table use. For the best dish of any coloured Kidney variety thirty-five competed. The first place was easily won by Mr. Peter McKinlay, Beckenham, for perfect examples of Salmon Kidney; Mr. Henry Sexton being second; Mr. Miller, Hampstead Park, Banbury, third; and Mr. Potts, gardener to Viscount Gage, fourth. The varieties mainly exhibited were large examples of the American Rose.

Messrs. SUTTON & SONS' PRIZES for twelve varieties, distinct, brought eighteen exhibitors, the collections being very superior. Mr. Donaldson, gardener to the Earl of Kintore, won the first prize and cup. In this collection Fenn's Bountiful was in a most perfect state, as were Veitch's Ashleaf, Porter's Excelsior, like Snowflake; Early King, Jersey Blue, Carter's Main Crop, and Breese's Prolific. The tubers were like wax models. Finer examples of culture were perhaps never seen. Mr. Potts, gardener to Viscount Gage, was second; Mr. Fenn, Woodstock, third.

Messrs. CARTER & CO.'S PRIZES for twelve varieties, six American and six English sorts. This was a very fine display. There were fourteen competitors. Mr. McKinlay had the first prize and silver cup with a bright clean collection; second Mr. James Betteridge, Chipping Norton; third Mr. H. Minchin, Hook Norton.

Messrs. HOOPER & SON'S PRIZES for nine varieties of American Potatoes, seven competitors. Mr. Peter McKinlay, Beckenham, won first and cup with large but clean and good examples; Messrs. Cox, Bros., Gosberton, being placed second; and Mr. Pink, gardener to Lord Sondes, third. The collections were very showy and attractive.

For Messrs. BLISS & SONS' PRIZES for three American varieties introduced to England in 1874-5 there were six competitors. Mr. R. Dean had the first place with Snowflake, Vermont Beauty, and Early Gem, all of great size and quality; Mr. Pink, gardener to Lord Sondes, Lees Court, being placed second; and Mr. Ross, gardener to C. Eyre, Esq., Welford Park, third.

For the prizes offered by Mr. John Coutts for three varieties of English seedling Potatoes there were ten competitors. Mr. Fenn, Woodstock, had the first award with splendid dishes of W. F. Radclyffe, Woodstock Kidney, and International Kidney; Mr. E. Bennett, School House, Enville, Stourbridge, being placed second; and Mr. R. Dean, Ealing, third. In this collection Dean's "First Early" was very fine.

Miscellaneous collections of considerable interest were staged. Messrs. Carter & Co. had a large display of seventy varieties of Potatoes, Beets, Marrows, and a splendid brace of Cucumber Tender and True. Messrs. Harrison & Sons, Leicester, exhibited sixty varieties of Potatoes of staple kinds. Messrs. J. & O. Lee, Hammersmith, had also a great and good display in a like number of varieties. Mr. Shirley Hibbard staged fifty varieties; Messrs. Bliss, New York, six new American sorts; and Messrs. Hooper & Co., Covent Garden, exhibited six unnamed seedlings of good appearance. From the Metropolitan Schools came ten dishes of tubers weighing 80 lbs. Mr. Fenn, Woodstock, exhibited twelve varieties of his seedlings of great beauty and correct table size. Noticeable amongst these were dishes of a second-early Round variety (certificated), also Early English Rose, and the fine dark Kidney Bountiful, which had been dug up in July, 1874, and which had kept in a wonderfully sound state.

Mr. B. S. Williams, Holloway, exhibited an interesting collection of decorative plants. The Exhibition was a very successful one.

BETTERIDGE'S QUILLED ASTERS.—We have received from Messrs. James Carter & Co. a box of the above Asters, which for distinct and varied colours and perfect form of the flowers it would be difficult to excel. Each bloom is semi-globular in shape, smooth, and exceedingly full of florets, having an elegant fringe of guard petals. The self-colours are white, lilac, violet, crimson, with intermediate shades; the bi-colours have

distinct white centres surrounded with bands of violet and crimson. These are excellent examples of an admirable strain.

### A USEFUL GARDEN BROOM.

THE best broom that has come under my notice for sweeping lawns and gravel drives is one that is very much used in this locality. One man can do more with one of these brooms than two can with the old garden besom, and it can be made by any garden labourer. I will describe, for the benefit of those who may not have seen them, the way they are made.

In the first place procure a strong handle about 5 feet long, and saw it down the middle the same way that the haymaking rakes are made. The forks should be about 18 inches long, and be pressed open about 6 inches wide at the points. Now take two pieces of light wood about an inch square, and place one on each side at the points of the tines. Next put two nails sufficiently long to reach through both cross pieces and the tines, then put a nail through each end of the cross pieces, and that will keep all in its place. This frame will last for many years, and all that will be required will be to replace the old twigs of birch with new twigs as they are wanted.

It will be easily understood that the twigs are to be placed between the two cross pieces, and be tied firmly, as the work proceeds, to the framework. The brooms can be made light or heavy, according to the work they have to do. It would want making a little heavier for sweeping-up grass mowings. It is an excellent tool for that purpose, and cannot be beaten. When completed the broom is the shape of a fan.—H.

### BOURNEMOUTH, ITS SCENERY AND VEGETATION.—No. 2.

In my last communication I noted some of the characteristics of this district. I will now take a survey of the Rhododendrons, which in some of the older enclosures have been planted rather extensively and are doing well. The public garden in the valley is well furnished with them. Several beds of the choicest kinds had been planted, and as care was taken to furnish them with more of the peaty substance than the site they were planted on afforded, I expect when flowering time comes round they will be found gay, and at the same time robust as well. I may add that in the planting of the park or garden alluded to care had also been taken to introduce trees and shrubs with variegated foliage, and those who know how well the *Acer negundo variegata* comes out under such circumstances can judge how well it was doing here. Mixed with or standing partly in front of other shrubs, its light airy appearance casts a charm about it which the other surroundings did much to set off. A variegated Dogwood was also used now and then to the same effect. Less sparingly, because more slow in growth, was the Golden and Silver-edged Hollies, both of which, however, as well as the other kinds, were planted in various places, and now and then a very nice Holly hedge was met with, of the value and beauty of which it is needless to descant.

Trees are not numerous. On a fully exposed bluff next to the sea I noticed *Pinus Picea* doing pretty well, much better than *Cupressus Lawsoniana*, which does not seem suited for the very edge of the coast, although it was thriving remarkably well a short way inland. Other trees at half a mile from the water, and sheltered by the friendly Scotch Fir, were also doing well; notably so was *Cedrus deodara* and a very promising *Cupressus macrocarpa* or *Lambertiana*, while I was told the *Wellingtonia* only did well for a short time and then seemed to go off. More promising seemed the somewhat capricious *Cryptomeria japonica*, which in places looked all that could be wished for, while in others it was yellow and sickly and evidently not at home. Deciduous trees were but poorly represented; in fact, their absence would seem to deprive the district of that appearance of autumn which they so forcibly call to mind elsewhere. I think such trees ought to predominate, but in the case before us this cannot well be for some years at least. Scotch Firs are there, and may either be made use of or destroyed, and the man would be very reckless who destroyed a tree of fifty years' growth to plant one that is uncertain to grow; and as we all know that Nature favours the growth of deciduous trees in districts where they are likely to grow, we may rest assured that if Elm, Ash,

Beech, Oak and the like had a liking for a soil and situation that has not evidently benefited much by cultivation until the commencement of the present century they would have been there, but as it is they are only conspicuous by their absence.

One tree I was, however, glad to see had been introduced with good effect, and that was the Birch, and that, too, in a place where it is but seldom met with—viz., the graveyard, and one yielding to none that I am acquainted with for beauty of site and copious adornment, not in architectural design, but in trees and shrubs, the sculptural embellishment being less imposing but always good; in fact I believe I am speaking within bounds when I say that nine-tenths of them were white marble, and that there were at least half a dozen fairly grown trees for one tombstone. Most of the graves are neatly ornamented with flowers, some growing, others in a cut state and frequently replaced, suitable paths winding amongst them; and with the white marble crosses and low kerbstones of the same material surrounding the sacred spot, the whole exempt from the soot and other polluting influences common in large towns, presented to view a charm not easily forgotten. The church, which occupied a platform at the bottom, had a good breadth of close-shaven lawn unoccupied all around it, the whole having that air of repose becoming a place of the kind. I noticed the Birch tree had been judiciously planted and was doing well, also the sombre hues of the Scotch Fir were not wanting to give appropriate effect to the enclosure. Other trees had also been planted and were doing well.

It will hardly be expected that other shrubs and trees not mentioned above were not to be met with in a place where wealth abounds and so much is done for outward display, for common and Portugal Laurels met one at every corner, yet not in so vigorous a condition as to indicate they were quite at home. *Laurustinus* were better, yet not so good as I have met with them elsewhere, and I do not remember seeing a good specimen of Sweet Bay, but *Cotoneasters* were quite at home, and ran over banks in the manner peculiar to themselves. *Escallonia macrantha* seemed also to do remarkably well, flowering with all the vigour of a *Fuchsia*; and I may add, when there seemed depth of soil, the *Fuchsia* did well also. The pretty fruiting *Pernettya mucronata* seemed to thrive like a weed, as also did one or two *Eunonymuses*, but they were more sparingly planted than I expected. The same may be said of *Ruscus aculeatus* and *R. racemosus*; the latter, by-the-by, I have never seen in robust growth anywhere, and looked for it in the mild climate of the south coast. The different species of cultivated Heaths could not do otherwise than look well where the wild one is so common, and double *Furze* I was told invariably did well, which might be expected when the common one is met with wild in so many places. *Berberis Fortunii* and *aquifolium* cropped-up frequently, but neither so good as is often met with; but Box, including the *Balearica* species, was in good force, and the ever-recurring Broom, than which, perhaps, nothing presents a brighter tint when in flower, was to be met with on the banks and steep slopes running down to salt water, vying in that respect with the *Tamarisk* and wild Heath in its capability of withstanding the spray; while one plant that seemed the most prominent on the north-western coast was scarcely to be met with here—that was the Willow. In fact, at Bournemouth deciduous trees seemed less patronised than they merit. The same may be said, in a great measure, of deciduous-flowering shrubs; for although occasional specimens might now and then be seen, their numbers as compared with their evergreen brethren were few indeed.

I have said that most of the buildings were of two or more coloured kinds of brick enriched in every manner the material is capable of, and great diversity can be made with these materials; and as each house was usually seated amongst trees and shrubs, creepers against the building had in most cases been dispensed with, and properly too; but now and then we could see that trelliswork as screens were more or less covered with *Clematis*, Ivy, Roses, and the like, the first-named of which seemed to do remarkably well, and on more than one occasion it might be seen rambling over the ground in rich profusion of flower. Flower beds of the fashionable class were frequently met with, but these were more under the form of a border margining the approach to the residence, as the anxiety for a plot of plain turf seemed so great that small beds were not much met with. *Geraniums*, *Verbenas*, and especially *Lobelias*, were duly represented; and with the ever-present (there as well as elsewhere) *Golden Pyrethrum* a good display was kept up. In the nursery of Mr. Enoch White on the Holdenhurst

road I noticed about a dozen varieties of Clematis in pots, trained balloon fashion and loaded with bloom, that would have been highly admired at a London show; while a look into the glass structures which crowded at the back and around the house disclosed a quantity of plants of all kinds, exotic and hardy, flowering and foliage, hardwooded and succulent, and in fact all that a wealthy community like that of a fashionable watering place are likely to require both for indoor embellishment and outdoor display, and those only who cater for the public wants in such places know what is really required.—J. ROSSON.

### VINES MILDEWED AND THEIR RENOVATION.

A CORRESPONDENT ("B. & W.") has sought for information under the above circumstances. We forwarded his letter to an able Grape-grower who had been similarly afflicted, and who succeeded in eradicating the mildew and procuring heavy crops of Grapes. The following is his reply, which contains practical matter which is generally applicable at this period of the year.

It is unfortunately too clear that the Vines have been overtaken by the destructive oidium, and that the attack has been a most virulent one. If the Vines have developed new foliage, and the wood is fairly strong and showing signs of ripening, the Vines may be preserved and future crops hoped for; but if the wood is weakly and soft, and the foliage small and lacking substance, then we must advise a renewal of Vines and borders. In the first case proceed as follows: When the foliage has fallen prune the Vines and thoroughly wash every portion of them and every portion of the house—wood, walls, and floor—with a solution of soft soap of a strength of at least a quarter of a pound to the gallon of water, using it at a temperature of 140°, which will destroy all fungus germs and leave the house clean. Next remove the surface soil from the border, carefully baring the roots (but not injuring them with the fork or permitting them to become dry by exposure), and replace with the best turfy loam that can be obtained mixed with inch bones or charred refuse, or both, and surface the whole with 6 inches of good stable manure. If in the spring heating material is at command to again cover the border, raising its surface to 90°, it will facilitate the emission of roots into the fresh soil, and the old Vines will become new again—that is, if new rods are gradually trained up. The fermenting material is not an absolute necessity, but is an immense aid, when carefully managed, in renovating old Vines by assisting the roots into fresh soil.

In the next case, if the Vines are extremely injured remove them and the border too, and plant new canes. The border being well drained, therefore simply make an exchange of soil, taking out the old and bringing in fresh loam. But perhaps this cannot be easily obtained, and in that case take the first draw of garden soil and mix with each cartload two or three bushels of inch bones, and of this make the border. Do this at once before the soil becomes cold and wet, and in the spring plant new Vines, and mulch over their roots with good manure. If the ordinary soil of the garden is such as grows fruit trees and vegetables well, rest assured that with bones added liberally and rich surface-dressings, it will, other points in culture being correct, produce satisfactory Grapes, and equal, in all probability, to what would be obtained by an expensive importation of turfy loam. Charred material, such as rubbish, thoroughly burnt, and soil scorched, is a valuable addition to any Vine compost, and such a heap can generally be scraped together in most gardens in the autumn.

A point of the first moment is that the border site be well drained, and of equal importance is it that the soil be put together in a moderately dry state, and before it has become cold by winter exposure. Neglect of these two points cannot be compensated for by any loam however turfy. If put together in a proper state, ordinary sound garden soil which will produce good crops of Pears and Potatoes will also produce good Grapes, and the Vines may be kept healthy for an indefinite time by frequently top-dressing the border with fresh soil, bones, and manure.

### NOTES AND GLEANINGS.

We have lately seen in London some remarkably fine examples of POND'S SEEDLING PLUM. Taking them indiscriminately, five of these fruit exceeded a pound in weight, and their average size was 8 inches in circumference. On

inquiry we found that these Plums had been grown by Mr. Beaulah, farmer, Brackenhills, Brigg, Lincolnshire, whom we know to be not only a good farmer but a successful cultivator of fruit and an able aparian. Mr. Beaulah has grown Pond's Seedling Plum 9 inches in circumference, and last year his young standard tree produced 14 stones weight (14 lbs. to the stone) of fruit. The fruit was of excellent quality. The synonyms of this Plum are Fonthill and Pond's Purple. In colour it is a fine dark red with grey dots, and is a valuable variety.

As a successful example of amateur GRAPE-GROWING, we give an instance of a vinery attached to a farmer's residence. The house is span-roofed, 27 feet in length, and 16 feet in width. The roof area is 486 feet. This roof has lately carried 400 bunches of Grapes, principally Black Hamburgs, varying in weight from  $\frac{1}{2}$  lb. to  $2\frac{1}{2}$  lbs. each. The berries were fine and well coloured. Of these Grapes the owner sold, beyond what he required for his own use, upwards of 200 lbs., and realised more than sufficient to pay his fuel bill and other expenses of management. The soil he used was sound turfy loam and bones, and to this was added heavy top-dressings of manure and copious supplies of water.

We have received from Mr. Burry, Gray's Inn, Warwick Court, Holborn, a remarkably fine specimen of the GIANT PUFF-BALL (*Lycoperdon giganteum*), measuring 16 inches in height and 44 inches in circumference. It was grown in a meadow near Bungay in Suffolk. It is edible when fresh, but the fine example sent us shows signs of decay.

### VINES DESTROYED BY WIREWORM.

HENCE we have at present date a plain and complete token of their power of destruction. Three vineries which were erected here in the autumn and winter of 1873 are almost a complete failure. The soil was procured from good old pasture-land, rather of a heavy nature, and slightly impregnated with iron; it was carted into the borders in a rough state, there chopped and mixed with lime, rubbish, bones, &c. The Vines were procured from a good source, planted, and when started looked all right; but it was not long ere they told that something was materially wrong—the growth stood still, foliage turned yellow, and for a time we were puzzled to know the cause; but on examining the soil there was no mistaking that wireworms were the cause, for every root was, or in the process of being, eaten. Around the collar of the stems were plenty of strong roots pushing for existence, but on the points of these they were busy feeding. What was to be done? Try and trap. This was tried partially, still they increased. Autumn brought a better growth—some canes fair, others deficient, some a failure. This spring we forked over the soil, destroyed what we saw of the enemy, and added some fresh soil; result this season even worse than last, the borders are completely swarming, and have all but destroyed the entire lot. The question now is, What is to be done? Can the present soil be cleared of them, and if so by what means? I have tried them in many sorts of poisons, but they seem to live as well in them as out. I would say to those who don't believe that wireworm eats or in any way destroys Vines, that they will be greatly enlightened by coming ere long and seeing them as busy at the roots as boys would be in a good bed of Strawberries.—JOHN GRAY, *Eglinton Castle*.—(*The Gardener*.)

### OUR BORDER FLOWERS—LUNGWORTS.

At least two of this family of early-spring and summer bloomers are said to be natives of England, but I cannot vouch for the accuracy of the statement. I am in doubt about their nationality, and look on them as only being naturalised on our island. However, be that as it may, we find them thoroughly at home with us, enlivening our spring gardens and borders with their cheerful presence and many-coloured flowers, and in some instances with their beautiful leaves.

What power there is in the language of flowers! I have, and no doubt others too, had the pleasure of seeing the languid eyes of an afflicted one lighted up with joy when a few flowers have unexpectedly been brought. With what emotion have the words burst forth from the lips of the suffering one, "How beautiful, how delightful, how delicious the perfume!"

Among flowers so welcomed are Lungworts. They are a very accommodating family; they will succeed in any moderately good garden soil and a rather shady situation, but will

bear full sunshine. *Pulmonaria officinalis* is in many gardens, but ought to be in all. Many years ago I saw this plant on a gravel hill among Nut trees in the month of April, the flowers peeping above the grass in profusion; I have not seen the like since. They are quite at home in what is termed "wilderness scenery," and are equally adapted for the rockery or any spot in the garden.

I have had *Pulmonaria siberica* and *Pulmonaria virginica*, but could discover no difference except in the name. The flowers are a dark blue, the leaves a dusky brown; it is one of the finest border plants we possess. When well established it is a gem of the first water, and makes a capital pot plant; it is useful for all purposes, and is increased by division, but it requires time to work up a stock.

*P. angustifolia*, *P. denticulata*, and *P. paniculata* are desirable plants when in bloom with their two-coloured flowers, beautiful leaves, dwarf habits, and long continuance in bloom. No plants at the season can be more effective. *P. mollis* and its white variety deserve far more extensive cultivation than they are at present receiving. *P. grandiflora* is a fine kind, and is of somewhat taller habit than many of the species.

A selection from this family are very effective when nicely put together. Some years ago I had a plant called *Pulmonaria nepalensis*; I had the same plant under the name of *Symphytum caucasicum*. Such variations of name cause confusion. The plant is one of our very best border plants. It grows 2 feet high. The flowers are a pretty blue and very enduring. It is increased by seed and division after flowering. It should have a place in all collections.—*VERITAS*.

#### LADY'S MANTLE.

In the month of June our fields and lanes are dressed in their gayest attire; I mean with flowers of various hues, for turn our attention whatever way we may we are compelled to see flowers here, there, and everywhere. What can delight us more than a stroll through the meadows and along our by-ways in the cool of our summer evenings, especially after a shower, to revive our parched earth, and cheer our senses by the effusion of a thousand sweets? While we gaze on the many beautiful flowers which deck our pathway, our attention is arrested by a lovely plant at our feet bearing the title at the head of this note. *Alchemilla vulgaris* is not brilliant in the colour of its flowers, but there is something attracting in its large beautiful leaves, and it might be made available as a border plant. The *Alchemillas* are but a small family of plants, and having three or four we call ours they become, at least to me, the more interesting. I believe if they were better known we should see them more frequently in our borders and rockeries. These remarks are prompted chiefly from a love of our native flowers, for many of them are equally at home under cultivation as in their native habitat. They may be successfully cultivated in moderately dry situations in good strong loam mixed with limestone grit, and some of the kinds do not object to sandy peat; they should have thorough drainage. They may be increased by division and seed, with full exposure.

*Alchemilla alpina* is said to be a native of Britain, and few plants present to our view a more beautiful silvery white appearance than this Alpine Lady's Mantle. It ought to be seen on every rockery and in all herbaceous borders. We sometimes see *Alchemilla alpina* and *A. conjuncta* confused together, but when seen side by side they are quite distinct. I find them useful as edging plants in contrast with others; their lovely foliage bathed in dew under the rays of the early morning sun has a very pleasing effect. There are shades of difference in the appearance of their foliage, but *A. alpina*, *A. pubescens*, *A. conjuncta*, and *A. pentaphylla* are the most desirable. For some of the family we are indebted to the Caucasus and Switzerland, while some are indigenous to "our own loved land."—*VERITAS*.

#### GRAPES AT THE EDINBURGH SHOW.

WITH regard to Mr. Dickson's statement in your issue of last week (page 270), I do not think that Judges have anything to do with the weight of a bunch of Grapes when cut from the Vine; it is the weight when staged in the show-room that they must go by. It would certainly have been a strange proceeding to have re-weighed the Grapes after they had remained two days and two nights in the show-room. As for being more than one bunch, I think the character and position of the gentlemen who acted as Judges is a sufficient guarantee

that there was nothing wrong on that score, especially as when lifting the Grapes off the boards and weighing them they had ample opportunity to inspect them. I regret that any unpleasantness should have arisen from the great gathering we had at Edinburgh.—*JOHN CURROB, Eskbank.*

It appears from a letter in your Journal of the 23rd inst. that Mr. Dickson, Arkleton, feels disappointed at the defeat he met with when competing for the prize for the heaviest bunch of Grapes at the Great Show in Edinburgh on the 15th inst. He appears to have, for months past, been living in the belief that all he had to do was just to go to Edinburgh, lay down his bunch, and take the prize. Most people will be of opinion that it would have been more prudent of Mr. Dickson to have pocketed the defeat and to have said nothing about it. His letter is apt to produce the impression (whether intended I cannot say) that the Judges cannot correctly weigh a bunch of Grapes, and that they do not even know what a bunch of Grapes is. The public, to whom Mr. Dickson appeals, will be very slow to suppose and believe that the evidence of the two parties who saw the bunch weighed before it left Arkleton should have guided the Judges in coming to a decision as to who was entitled to receive the prize, and not the evidence of their own eyes and senses. This is an opinion that cannot be entertained.

The two bunches were weighed in the same room, on the same weights, by the same gentlemen, and before dozens of witnesses all looking on and checking the weights. Evidence like this should satisfy any reasonable man. Did Mr. Dickson weigh his bunch of Grapes on the morning after the Show, and did he find it more or less weight than the Judges made it?

As to what a bunch of Grapes is, the bunch from Eskbank was a much more compact, more beautiful, and better-shaped bunch than the one from Arkleton; the latter appeared rather to have a number of long arms or string of bunches, somewhat more like a shot Cauliflower than a good neat bunch of Grapes. The heaviest bunch was the finest variety also; and it was certainly not the opinion of persons well qualified to judge Grapes, and who saw both bunches at the Show, that the berries on the lesser were better than those on the larger bunch, but quite the reverse.—*D. E.*

MR. DICKSON would like to "hear the opinion of two or three able men who are not interested in either of the bunches" as to the fairness of the award for the heaviest bunch.

I am certainly not "interested," and am "able" to say that the weighing was conducted in the most transparently fair manner, for I watched the operation closely. The Eskbank bunch was not only the heaviest, but it was the most compact and staged in the best condition. The Arkleton bunch was much rubbed and appeared to have received injury in transit, which spoiled the appearance of the berries. The berries of both bunches were very good. That, however, is not the question, weight alone being the point at issue; and on this point I cannot see how the award can be reasonably called in question.

Both the bunches appeared to be fairly grown; and while I am not surprised at Mr. Dickson's disappointment, I am surprised to hear that "half a dozen principal Grape-growers and prizetakers at the Show" should consider the compact Eskbank bunch to be "two bunches." What does this mean?—*AN ENGLISH GRAPE-GROWER.*

#### VIOLAS FOR SUMMER BEDDING.

VIOLAS have long found a place in masses in our spring gardening, but it is only of late years that their capabilities and merits in summer and autumn flower gardening have been recognised and tested. There is not a doubt but Violas, like most other plants, succeed best in certain localities, and under certain peculiarities of soil and climate. Still, from what we have observed for several years past, we are of opinion that in nine cases out of ten they are not properly cultivated, and that in many instances where their blooming period is cut short by drought and hot sun it is because they are not treated in a manner that enables them to compete with adverse climatal conditions.

To make Violas bloom continuously throughout the summer, in the drier localities of the country, the ground should be as deeply worked and as effectively manured as a quarter that is intended to grow fine summer Cauliflower. Even in the wettest localities, rich deep soil is a condition under which

they are most satisfactory and effective. And so effective and continuous are they as plants for massing in summer, that we know of no other class that will yield the same solidity and profusion of colour and bloom.

The way to develop their capabilities to perfection is very simple, and places them within the reach and enjoyment of all who can command hand-glasses or cold frames, and ordinary garden soil and manure. For summer and autumn blooming the cuttings should not be put in too early. The character of the early cuttings is never such as produce free-growing and continuous-flowering plants. The very end of September or early in October is the best time to propagate. Then is the time that under the influence of cool moist nights they produce plenty of young healthy shoots near the necks or bottoms of the old plants. These small healthy growths that have never formed nor produced a bloom bud are the cuttings that root the most freely, winter with least care, and ever afterwards do the best, and bloom the freest and longest. It is undesirable to put in long cuttings with a shank and a dangling top. Two joints in the ground and two out of it is quite sufficient. They should be made in a cool shady place, and put in the frames and watered and shaded without being once allowed to droop. Any ordinary light garden soil will root them, but a mixture of about equal portions of loam, leaf mould, and river sand is best; and 5 inches of this soil, resting on a rather firm bottom, to prevent their sending down their roots deeply, and from which they can be removed in spring with a ball and all their roots, is preferable to a great depth of rich open soil. Kept close, rather moist, and shaded from bright sun, they root with scarcely one per cent. of misses, and get well established before winter sets in. Plenty of air after they root is indispensable; and a slight covering over the glass in very severe weather is about all the attention they require till planted in spring where they are to bloom.

As can be gathered from what has already been said, the soil in which they are to bloom should be deep and rich; and under such treatment few plants are so effective for the same length of time, and at the same expenditure of time and labour. The end of March or beginning of April is a good time to plant out, according to the season and state of the weather. They should be lifted with all the soil possible adhering to their roots; and if the weather be dry at planting time give them a good soaking of water, after which they generally take care of themselves.

The new varieties of these sent out yearly are numerous, and we have tested a very great number, and selected comparatively few. The most effective violet-coloured one that has been tried is *Viola cornuta* Perfection: nothing of the same colour that has been tried approaches this one for genuine usefulness and effect. It is alike suitable for large beds and scroll-work. It is a compact upright grower, and requires to be planted thickly. The best purplish blues tried are *The Tory*, *Charles Dickens*, and *Alpha*. Of yellows the two we grow most of are *Perpetual Yellow* and *Yellow Gem*. The former is the most wonderful plant to bloom we have ever seen. It blooms all winter in the cutting frame, and blooms until the snow covers it up next winter in the beds. As a pale lavender *Lilacina* is most thought of; and among whites, *Purity* is probably the best of a great number tested: a good white has yet to be raised.

The effect of these in masses and long lines is very striking. For filling the old Egyptian scroll to be met with in many gardens—when the centre circles are filled either with *Alyssum* or some golden-leaved *Geranium*, and the S's with *Viola cornuta* Perfection, and the outer part of the design with *Tropaeolum Cooperii*—the effect is charming.

A panelled border on a large scale, with a massive groundwork of *Viola Tory*, with panels of variegated *Dactylis*, having a small specimen of variegated *Acer* in the centre of each panel, with two or three lines of *Viola Perpetual Yellow* next the bluish-purple groundwork of *Tory*, and a margin line of *Viola Perfection*, is very effective, particularly in the evening. As a mixed bed few combinations are more chastely beautiful than one planted plant about of *Polemonium caeruleum* variegatum—a plant not nearly so much grown as it should be—and *Viola Perfection*. The variegated *Periwinkle*, young plants, and *Viola Tory*, are also very effective planted in the same way as the *Polemonium* and *Perfection*.

A groundwork of *V. Perfection*, with margin lines of gold, and panels of white *Stock* or *Centaurea ragulina*, makes a very sweet combination; many other combinations of hardy and easily-raised plants, such as those instanced, can be carried

out at half the expense and labour required for those that have to be raised in heat, and that do not last in bloom above half the length of time.

Mr Gray, Eglinton Castle Gardens, has succeeded in raising some purple, yellow, and white varieties, which, both for habit and general effect, are superior to any yet in cultivation, and we hope they will soon be distributed.—D. T.—(*The Gardener*.)

## NOTES ON VILLA AND SUBURBAN GARDENING.

**ROOT-STORING.**—We have now arrived at the beginning of October, a month rather busy in the matter of taking-up, collecting, and storing the various crops of the garden. Most if not all root crops appear to be fairly advanced towards the condition for housing. Fine weather should always be chosen for the above work. I do not like the soil to be in a sodden state when a crop, such as Carrots for instance, is taken out of it; neither are these crops in such a fit condition for keeping when much wet succeeds a period of fine weather, such as we have just had. The roots under these conditions take-up too much moisture for long keeping, and it requires a longer period to have them thoroughly dry before packing away; therefore, as the weather is at present threatening, it would be well to take-up Carrots, Beet, Potatoes, and Onions. Parsnips, take-up as wanted, but leave the general crop in the ground. Salsafy and Jerusalem Artichokes may also remain in the ground and be taken-up later in the season.

All roots should be judiciously thinned before storing. I like to cut the tops off Carrots and Beet at two different times: first, when taken up the tops are cut half down, but after they have been under cover and become dry the tops of the Carrots are cut close off, and those of the Beetroots to within 2 inches of the root. The points of neither are touched. I have often found that if a Carrot begins to rot it does so quite as often when it is cut at the point as it does at the top. Beetroot is generally one of the best of keepers under the usual conditions. Generally speaking roots have nothing but makeshift places in which to be packed away—either too damp or where there is not sufficient protection from frost, or the material in which they are packed is of the wrong sort. It should be thoroughly dry, and not liable to go soon to decay. Clean dry sand is, perhaps, the best of all, but coal ashes are the worst. I have kept roots well in chopped straw when sand could not be had. They are put on a layer of this at the bottom, and upon boards to keep clear from the ground, then the chopped straw in about 8 or 9-inch lengths is laid crosswise to the roots. In all cases the roots are laid-up root and point alternately, and if in a cool but not too dry a place they remain plump through the whole winter. The object of having the straw short is, that it can be easier laid-in, and again can be easily removed a little at the time as the produce is taken away, and during the winter months when the roots require to be looked over the work can be done much quicker and cleaner.

It is sometimes necessary during winter to protect from frost by some sort of covering. Now this should be moved and replaced as often as the severity of the frost comes and goes. I mean that if a sudden thaw succeeds a frost the covering should be removed, otherwise it is apt to bring on a kind of sweat, simply from the sudden extremes of temperature, which is almost certain to generate decay. Again, if the roots are packed in sand or dry earth it should be in the house or under cover, and free from any contact with moisture; and when once a sufficient quantity is collected in the house it is not well for it to be taken out again except for the purpose of cleaning or drying afresh, when it will last some years with trifling additions. I have stated this because many persons have a difficulty in obtaining sand, which gardeners as a rule can get plenty of.—THOMAS RECORD.

## DUNEEVAN,

THE RESIDENCE OF J. MONTOSH, ESQ.

A FORTY-MINUTES run by train from the metropolis will in almost any direction take the visitor to some delightful country spot, which by its proverbial salubrity, its pure air and agreeable natural landscape is selected by the affluent—city merchants and retired professional men—as affording scope for isolated and more or less pretentious country residences. Such a place would Walton-on-Thames appear to be and the district surrounding. The traveller who alights at Walton station on the London and North-Western Railway is at once satisfied that he is clearly beyond the land of cockneyism. The scene savours of quiet country sweetness, and is, in fact, "truly rural."

The aspect is a woody one, and the ground is undulated. The roadsides are flanked by masses of verdant Oaks and Elms, and the distant hills, or rather knolls, are topped with

sombre masses and clumps of Firs. In the foreground are Ferns, and Brambles, and Heath. The soil is sandy and the site dry. In the clearances—the open fields—are sufficient trees left as single specimens to add to the beauty of the neat cottages and more imposing mansions which stud the landscape—prominent objects in a leafy framing. I need not tell of the trees by the way—the glossy Chestnuts and the graceful Beeches, or the brilliant glimpses of Pelargoniums which shine through the fences of cherished gardens bounding the road to Ostlands Park. My object is to find Duneevan and see what is to be seen in the garden of a garden-lover, and to tell other garden-lovers something of what Mr. McIntosh has done to make the surroundings of his home attractive and enjoyable.

Duneevan is about a mile from the railway station. "Turn to the left," said the porter, "then take the second turn to the right, then the first turn to the right again, and you will see Mr. McIntosh's white lodge on the left." Ah, three rights again, history repeating itself, thought I, and the Walton porter is as clear as the Balham butcher's boy. I had no occasion to ask another question, for I found the white lodge with ease. Mr. McIntosh's mansion is a white brick building with stone dressings, which contrast well with the fine Beeches and Conifers on the lawn of the little carriage frontage. Faultlessly clean and neat is the outside, but let me first tell of my greeting inside. It was a queenly one—i.e., a bouquet of Roses.

This bouquet demands a note. In the centre of the room is a circular table, and in the centre of the table a slender glass vase with one solitary bloom of Gloire de Dijon; around this is a circle of other vases and other Roses, and beyond this other circles until the edge of the table is reached, the vases decreasing in height from the centre, those of the outer edge being tiny gems of 2 inches in height. This table of 280 blooms in separate glasses is a truly regal bouquet of Roses; as one bloom decays it is replaced by another, so that this table of Roses is lastingly sweet and beautiful.

Now let us look outside. The garden front has a north aspect. Close to the house is a terrace, on which are arranged the flower beds. But this terrace is not a dainty, formal, artificial work of art; it is a bold bank which Nature has formed, and sweeps down in precipitous and wavy undulations to the grounds below. It is not descended by artfully-hewn stone steps, but by natural curving walks is the lower ground reached. This ground is beautiful both by disposition, keeping, and the decorative subjects employed. It is a lawn of bold undulations and of perfect keeping, so perfect that not a Dandelion or even a Daisy is permitted to exist on its not inconsiderable surface. It is dotted with trees of noble growth. There is the venerable Oak with a girth of stem of 23 feet, Larch 80 feet, and towering immensely higher is the graceful Birch with silvery stem, and in the autumn is of golden fountain-like contour. The Birch associated with Conifers is one of the most ornamentally effective of forest trees. Here, too, are some noteworthy Conifers; but few finer and more perfect Wellingtonias can be found than one specimen of 40 feet in height, but it is dwarfed in comparison with a fine old Cedar of Lebanon. Smaller, but of their kinds still more noticeable, are *Cupressus Lawsoniana argentea*, 10 feet high by 8 feet at the base, and *C. Lawsoniana gracilis* is 14 feet by 10. Of *Abies Albertiana* is a splendid pyramid of 25 feet, of rich colour and extreme elegance. *Araucaria imbricata* and *Cedrus deodara* are also fine, with many others which must be passed over. But I must not pass over, lengthy as is its name, one of the finest plants extant of one of the finest of lawn Conifers—viz., *Cupressus Lawsoniana erecta viridis*. It was planted in 1867, and is a dense imposing column 15 feet high by 4 feet in diameter. Why is not this handsome variety more freely grown? It must be because it is not sufficiently known. Both in habit and in its brilliant green colour it is one of the most distinct and attractive plants of this family, and ought to spread far and wide. Besides these are elegant examples of *Cryptomerias* and the best of the *Retinosporas*, a grand plant of *Picea magnifica* 15 feet high, with many other choice and well-grown Conifers. These are planted on the smoothest of smooth lawns.

Another main feature of this beautiful garden are the Rhododendrons. The collection of these is rich and extensive, every new variety being added, and the whole collection carefully and correctly named. These plants grow with extraordinary vigour, and are tended with skill and care. They are planted in thousands on banks and in beds of various forms, thought-

fully disposed with a view to increasing the general effect of the grounds. These beds must be grand in June, but they are grand now and throughout the summer, and this brings me to what is a remarkable sight.

I had heard that Mr. McIntosh had *Lilium auratum* growing in the open ground 11 feet high, and that some clumps of four stems had 130 blooms. I have now seen that this is really so. This grand *Lilium* is at home here. It is grown by hundreds and in extraordinary luxuriance. The bulbs are planted near the front of the Rhododendron beds about 9 feet apart, and between each a standard Rose. The huge light blooms of the Lilies lift their noble heads out of the rich green beds, and fill the air with fragrance. The bulbs were planted 6 inches deep, and there they remain from year to year without any protection from frost. The bulb which has produced the kingly spike of 11 feet was planted in 1870. This bulb has thrown up two spikes, the shortest being 9 feet, and the pair are carrying twenty-three blooms. It is a noble growth of a noble Lily. Another single stem may be noticed as carrying twenty-four grand blooms, most of them being 14 inches in diameter, the circumference of the stem of the plant being 3½ inches. In another part of the grounds are less tall but magnificent clumps, one of which has, or had until recently (for they are fading now) 180 expanded blooms, and on three clumps together were 250 of these glorious flowers. Some idea of their effect is afforded by the engraving, fig. 66, where the figure of Mr. McIntosh is included to give a relative idea of the size of the plants, but which, however, are dwarf in comparison with others in the grounds. They vary, indeed, in height, size of bloom, and colour, some being suffused with crimson, while others are paler. The natural soil is sandy loam with an admixture of peat on a sandy subsoil. These plants are well supplied with water, but no liquid manure is given them for fear of injuring the valuable Rhododendrons amongst which they are planted. They are supported by galvanised wire stakes, which are made in lengths with sockets, so that they can be lengthened as the plants increase in height. These beds are disposed in different parts of the lawn, and the whole of them are planted with these fine Liliiums. The front of this garden is bounded by a fine and spacious stream of water—the Broadwater—and along this stream is a straight walk, having on one side a lawn sloping to the water and ornamentally planted, and on the other a large raised bank of Rhododendrons. This walk, which approached 100 yards in length, is also fringed with Liliiums, and at one end a walk conduits to the upper ground through perfect bowers of foliage. This, though not a large garden, teems with fine plants and fine features, and it is kept in the highest possible state. The Liliiums bloom from July to November.

The flower garden at Duneevan is also particularly gay. The centre bed is *Coleus* banded with *Centaurea* and edged with *Alternantheras*, and this is flanked by large beds of Pelargoniums. There are splendid beds of Indian Yellow, which is still one of the best bedders; Lord Palmerston, Amy Hogg, and Lady C. Grosvenor. The edgings to these beds of Ivy-leaved Pelargonium *L'Elegante* are better than is commonly seen of that delicate grower. There are also beds of *P. Amaranth*, very effective; *Corsair*, excellent; *Rev. T. F. Fenn*, intensely bright; *Rev. C. P. Peach*, and *Miss Saunders*. The double blue *Lobelia* used as an edging plant is also in fine condition. A small conservatory is attached to the residence, and which is now gay with well-grown standard *Fuchsias*, &c. There are two vinerias which the gardener, Mr. Taylor, has managed very well. A new kitchen garden has been made, the land costing nearly £1000 an acre, and a good collection of fruit trees is being established, some of them bearing enormous crops of fruit. The soil is light and sandy, and the pasture lands are burning up, yet the garden crops are healthy and vigorous, thanks to full supplies of sewage, which is wisely preserved and freely used. This is altogether a charming garden, not provided, as the owner says, that he should "eat its fruits and grumble," but is thoroughly enjoyed as a principal means of healthy employment. Mr. McIntosh has good reason to enjoy such a place, and his gardener is to be complimented on its excellent management.

An interesting fact must not be omitted. Mr. McIntosh is a lover of birds (not in cages), and the confidence existing between his feathered friends and himself is very striking. Robins fly out of the bushes, and not only feed from his hands, but alight on his beard and pick the crumbs from his mouth. It is most interesting to witness these friendly birds (or perhaps it may be the same bird which I saw do it over and over

again in different parts of the grounds) fly up and take the crumbs from the mouth of their friend and preserver, and alight and eat them on the lawn. What patience and training on the part of Mr. McIntosh! but then, what a reward!—W.

#### A VISIT TO ARKLETON.—No. 1.

At a time when more than a common amount of interest is evinced in Grape culture, and especially in the production of the leviathan bunches which have lately startled the horticultural world, a brief record of a visit to Arkleton—the home of some of the most extraordinary Grapes on record—cannot fail to possess a measure of interest.

I am indebted for my Arkleton visit, which was a September one, to the kindness of a Scottish laird—W. E. Malcolm, Esq., of Burnfoot, under whose hospitable roof I spent a few memorable days. Shall I say a word about Burnfoot? It is a charming spot situated on the banks of the foaming, tum-

I name this as an honour to a man whom success has not spoiled, and as a lesson which almost every instance of success teaches—that he who wins must work.

Arkleton is the residence of John Jardine, Esq., situated in one of the most picturesque parts of Eskdale, about five miles from Langholm, and about 500 feet above the level of the Solway. The grounds and gardens were planned by Mr. Little, of the firm of Messrs. Little & Ballantyne of Carlisle, and were executed by the present gardener, Mr. Dickson, in the years 1863 and 1864. The subsoil is gravel; indeed, when Mr. Dickson entered on his duties the greater part of the kitchen garden was little more than a gravel bed. As a rule fruit trees thrive well here; very few standards are grown, but the walls are covered (both inside and outside the garden) with a very good selection of Pears, Plums, Cherries, and Apples, and healthier and better-looking wall trees are seldom to be met with.

The vineries consist of two houses (Shaw's patent), each

Fig. 97.—BUNCH OF STRIAN GRAPES AT ARKLETON.

bling, rollicking Esk. The mansion is sheltered by trees which would be fine but for the majestic hills on every side, which make trees look small and men feel puny. In the gardens Roses grow with great luxuriance, Gladioli possess extreme vigour, and the *Calceolaria amplexicaulis* I have never seen excelled. The healthfulness of the plants named is doubtless a consequence of the heavy rainfall of the district, so heavy that Wheat cannot be grown to advantage. In the garden also were excellent crops of fruit, and very good Grapes. But although the grounds are delightful and the garden well managed, no attempts are made to produce anything beyond the daily requirements of the household. Mr. Malcolm therefore, to supplement the ordinary culture of his own garden, afforded me the convenience of his stable to see the extraordinary Grapes of Arkleton; for this I publicly record my acknowledgments, and I will now endeavour to describe what I saw. I saw not a great place of aristocratic mein, but a snug, small, unimposing home of a retired country gentleman. I saw not an extensive and sumptuous garden with a superintendent having unlimited means and men at command to carry out his every wish, but a plain square enclosure of about an acre, and the man who has grown some of the most extraordinary Grapes in the world digging-up old Cantharoid stalks.

30 feet long; the Vines are planted inside, but there is an outside border as well. Each of the borders are 14½ feet wide—that is, the houses are 14½ feet in width, and the outside border the same. Mr. Dickson is a great advocate for inch bones mixed with fine fibry loam; of this compost he gives the Vines a liberal top-dressing every year, and during the growing season he gives the borders liberal waterings of liquid manure water taken from a tank in the farmyard. He never allows the Vines to make any growth beyond what he considers proper for keeping them in a good healthy condition. He generally leaves three leaves beyond the bunch, and keeps them at that, going over them perhaps once a-week, taking off all unnecessary growth. After the fruit is all out from the Vines he gives the borders a good soaking of water, not thinking it good for them to be kept so dry as many people keep them at that stage; indeed, he believes that they should never become very dry, and that Vines require more water than is commonly supposed. The borders never have a covering of any kind, although an average of 64 inches of rain falls in the year. This year there has been no semblance of thrips, red spider, nor any other disease to which Vines are subject.

The Vine that carried the bunch of 25 lbs. 15 ozs. when weighed in Edinburgh, but which Mr. Dickson states weighed

26 lbs. 8 ozs. when cut, has only been planted four years; it was grown from an eye taken from an old Vine which had produced very large bunches. The second year it was planted a bunch was cut from it that weighed 14 lbs.; the third year one which weighed 16 lbs. 6 ozs.; and this year the same as given above. The exact measurement of the Vine from bottom to top is 20 feet. The wood of this year's growth is  $2\frac{1}{2}$  inches in circumference, the old wood being  $5\frac{1}{2}$  inches in circumference, and a few of the leaves measure 21 inches by 18 inches, and are extremely thick and leathery.

Such is a brief unvarnished history of a now-celebrated Vine. As seen hanging the huge bunch presented an extraordinary sight. The stem was an honest stem—of that there could be no doubt. It was as smooth, clear, thick, and almost as hard as a walking-stick. Its ponderous shoulders were tied straight out, and measured across them 2 feet 3 inches; the length of the bunch was also 2 feet 3 inches, and its circumference, following the contour of the shoulders to the body of the bunch, precisely 8 feet. The accompanying illustration, fig. 67, from a photograph taken when the bunch was hanging on the Vine, gives as faithful an idea as is to be obtained of this remarkable example of Grape culture. The berries of the bunch were of a full size—indeed, Mr. Dickson had paid too much attention to quality of berry, and certainly sacrificed many ounces in weight by so freely thinning; they hung loosely, and were as large as berries of Syrian usually are on medium-sized bunches. The Vine was only permitted to perfect that one bunch. A neighbouring bunch of the same sort measured 2 feet 8 inches in length and 1 foot 7 inches in diameter; Alicante, 1 foot 8 inches across by 1 foot 8 inches long, another bunch being 1 foot 6 inches by 1 foot 6 inches; Black Hamburg was 1 foot 8 inches across and 1 foot 2 inches in length; and Mrs. Pince's Black Muscat and Black Prince 16 inches by 16 inches. Such are a few of the measurements, and now for a list of the weights of some bunches of Syrian which have been produced; and although they are not individually the heaviest on record, they are as a series probably unequalled in the annals of Grape culture.

In the year 1869, at the Edinburgh International Exhibition, the first prize was awarded to a bunch weighing 16 $\frac{1}{2}$  lbs.; in 1870 the first-prize bunch at the Royal Caledonian Society's Show weighed 19 lbs. 5 ozs.; in 1871 the first-prize bunch at the same Society's Show weighed 18 lbs. 7 ozs.; in 1872 the first-prize bunch at Glasgow weighed 19 lbs. 6 ozs.; in 1873 at Manchester the prize bunch weighed 16 lbs. 1 oz.; and in the same year another bunch at Glasgow weighed 16 lbs. 10 ozs.; then came the bunch of the present year, weighing (by the Judges) 25 lbs. 15 ozs.

Is not that an achievement without a parallel? and would not a commemorative medal be worthily bestowed for such an example of skill? The few pounds won in money have no doubt been useful to a plain hard-working man, but should he not have something tangible to hand down to his children? and would the patrons of horticulture, by enabling him to do so, be doing anything more than simple justice both to the science they represent and to the man who has so well brought out its resources in the important branch of Grape production? It may be replied that others have done well also. Well, let them be honoured too. Many there are who do infinite honour to the craft in a less sensational but not less worthy manner, who cannot bring their works before the multitude, and are never heard of, but who plod on in honourable obscurity; but when their works are seen let them have a reward.

In addition to the vineries there is at Arkleton a Peach house 180 feet long, with a drum trellis running along the front, and occupied with fine healthy trees of Peaches, Nectarines, Plums, and Cherries, all of which bear annually fine crops of fruit. In a future communication I will again direct attention to the Vines at Arkleton, noticing the border formation, and search for the causes that have contributed to such great results. Able men have no secrets, and Mr. Dickson not only permitted me to see everything connected with the garden, but generously replied to all questions concerning his mode of culture.—J. W.

EDINBURGH HORTICULTURAL EXHIBITION.—In the report of the Great Flower and Fruit Show at Edinburgh, when mentioning the judging it is said, "For perfect fairness, smoothness, and celerity no system can be better." Yet, in my own case, my gardener sent to the Show four variegated Geraniums. These were marked "first prize," and the prize slip remained

on his card till nearly 2 p.m. of the first day of the Show. It was then taken off, and affixed to the card of a competitor, and no satisfactory reason was given for this alteration.—R. N. S.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

SINCE last writing under this heading we have had copious showers of rain. The ground had become very dry, and all autumn crops were showing the effects of the want of moisture at the roots. We had not been doing much except hoeing and weeding the ground, and we shall now have an opportunity to weed all the walks. This work is always best done after rain. Endive comes in useful for mixed salads in autumn and winter, and for this purpose it must be blanched. The best way is to invert a flower pot over each plant, and as the Endive is used the pots can be removed to other plants, and in this way a succession of it is obtained. The holes in the bottom of the pots must be stopped. Young plants may now be put out for occasional crops.

Potatoes should now be lifted for winter use. When the haulm is quite dead there is no benefit derived from leaving the tubers in the ground. The "curl" was very prevalent on the plants in the fields this year, and it was certainly worst on the part where the Potatoes had been allowed to remain in the ground long after the tubers were ripe. One would fancy that the reverse would be the case, and that the better-ripened and firmer the Potato the stronger would be the plant next season, but in actual practice we do not find it so. There is no doubt but that the "curl" was known half a century ago. McIntosh writing in the "Practical Gardener," a book published in 1828, says, "Such as are intended for seed should not be allowed to become too ripe, as in that case they are more subject to the disease called the 'curl,' which is often very detrimental to the crops." On the farm at Loxford many acres were planted with Dal-mahoy's, the seed tubers of which were some time in the ground after the haulm had died, and the whole of the crop was severely attacked by "curl."

We have been gathering enormous quantities of Scarlet Runner Beans from two rows of about 40 feet in length each. They are a very useful vegetable to us. As we have previously stated, the difficulty we have to obtain anything like decent crops of Peas so late as this is very great. It is not altogether the climate that is in fault with us, the soil is too light; this is in our favour in May, but against us all through the summer and autumn. We saw at Burghley Park, Stamford under the excellent management of Mr. Gilbert, some fine rows of Peas bearing good crops the other day. Mr. Gilbert's plan is to dig out the ground as for Celery trenches, but not quite so deep, the Peas are then sown in the trench in rich soil. Artificial watering was not approved of, but in exceptionally dry seasons it would be well to water the rows, and whatever quantity was applied none would be wasted, as the roots, being lower than the surrounding level, would absorb all the water.

### ORCHARD HOUSE.

All the trees from which the fruit has been gathered have been either *potted* or *top-dressed*. Those trees that were repotted last year have been top-dressed this year. We report every alternate season. When we were accustomed to report in November we found the trees did not set their fruit so well, but since this operation has been performed in September the trees become established before the leaves fall, and the fruit always sets well, at least if it does not do so the fault is not in insufficient root action. We have in previous seasons said that some attention is required to see that the leaves do not flag too much; dewing them with the syringe and keeping the house rather close will prevent any injury. Top-dressing may be done later in the season, but it is just as well to do this at the same time as the potting. It will be a saving of time to have all the work over at one time. Following the practice recommended by Mr. Rivers, malt or kiln dust has been used in former years, but it is not readily obtained here; and as stable manure and turfy loam both pretty well rotted, in the proportion of one of the former to two of the latter, answers equally well or better, we do not trouble to obtain the kiln dust either for summer or winter dressings. It is best if the loam and manure can be mixed and laid up in a heap for two or three months. The way in which the trees are dressed is this:—With an iron prong (the time of a Potato-fork broken off is as good as anything, or a screw-driver answers well), fork-out as much of the surface mould as possible to half the depth of the pot. It is not desirable to work too close to the stem; a space of about 8 inches will be as much as can be obtained in a 15-inch pot. The compost ought to be rammed in rather firmly, because the organic matter decays during the winter. The fresh material is very soon filled with new active rootlets.

### PINERIES.

We find that fruit ripening and others approaching to that

stage does very well in a lower temperature than is usually thought necessary to be maintained in the fruiting house; for instance, in our fruiting house there is also a very heavy crop of Muscat Grapes ripe, and to keep them in good condition it is necessary to air freely night and day. So far the temperature does not fall below 60° at night, but as the nights become colder 55° will be the minimum. Lower than this it is not desirable to go, and with a little management the Pines ripen well and are of excellent flavour. Succession houses require the temperature to be regulated by the state of the plants. One of our houses containing a number of Queens that have made their growth is now kept at a minimum of 60°, and will fall to 55° or even to 50°. As the nights are colder plenty of air is admitted by day, and a drier atmosphere maintained than when the plants were in full growth. This treatment will rest the Pines, and they will be in good condition to start for fruit at Christmas.

Our suckers were potted later this year, as it is intended to pot them again in the spring and to grow them on for fruiting in 1876. For such a purpose it is quite early enough to pot the suckers about the first week in September, further north a week earlier might be as well. If it is intended that suckers of this year should fruit next year, then they ought to be taken off in June or early in July; indeed, some of the best Queens we ever saw were ripened in June from suckers of the previous June. There is no difficulty in doing this. The suckers are potted in 6 and 7-inch pots, and as soon as the pots are filled with roots the plants are repotted into 10 and 11-inch pots, and by the first week in October these will be quite filled with roots, and the plants after a little rest may be started about January the 1st. It will be necessary to maintain a night temperature of 70° with a good rise by day; indeed with sun heat we have had the thermometer to 100° without any injury resulting from it.

#### PLANT STOVE AND ORCHID HOUSE.

One plant of easy culture when its requirements are known is *Disa grandiflora*. It has flowered two years in succession in a small span-roofed house here, and the ventilators have been fully open night and day all the time. The plant is repotted annually about this time; the pots are filled half full of drainage, and over this some fresh sphagnum moss is placed. The compost is turfy peat and fresh sphagnum chopped up; the sphagnum is also encouraged to grow on the surface of the compost, which it will do if the plant is syringed twice daily. Under this treatment and a moist atmosphere the plant will succeed well. The night temperature in winter should be about 45°. In summer, when in full growth, shade from the sun. If the house is facing north so much the better for the plants. The large brilliant crimson flowers that open in July are very striking in appearance. Another very fine Orchid for greenhouse culture is *Cypripedium spectabile*. It requires the same treatment as the other as regards soil, temperature, potting, &c. The flowers are white tinged with pale rose; others are tinged with a deeper rose or crimson. In the stove the *Calanthes* are rapidly approaching the flowering stage, and will be very valuable to us, as flowers are scarce at present. *Bougainvillea spectabilis*, with its beautiful mauve-coloured bracts, should be encouraged to flower in the autumn. It will flower in May or June, and after being rested a little will start again. It is new in flower with us. It is quite as well to let the stove plants have as much sun as possible now. *Orchids*, except *Phalenopsis* and some of the *Cypripediums*, with a few other species, are much benefited by the sun at this time. *Dendrobiums* and *Cattleyas* will flower much and more freely when the pseudo-bulbs are ripened under exposure to the sun. Any young plants of such subjects as *Dipladenias*, *Ixoras*, or, in fact, any hardwooded stove plants, should be encouraged to grow, and, if necessary, they should be repotted. The plants will yet have time to become established in the pots before the dark days of midwinter. An over-moist atmosphere is injurious at this season.

#### FLOWER GARDEN.

The Auriculas have been removed from their quarters under the north wall to a southern aspect. We have potted Carnations and Picotees, two plants in a pot, the strongest in 48's and the rest in 60-sized pots. The Pinks will be planted out as soon as the ground is ready for them. As yet no other bedding-out plants have been propagated except zonal *Pelargoniums* and *Centaureas*; all others will be put in in the course of a week, *Calceolarias* being left to the last.—J. DOUGLAS.

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

JANUARY.—Autumn October 18th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.  
LOUGHBOROUGH.—November 15th and 16th. Mr. W. Pallett, 55, Baxtersgate, Sec.

### TRADE CATALOGUES RECEIVED.

Messrs. Hooper & Co., Covent Garden, London.—*Catalogue of Bulbs, Fruits, and Garden Requisites.*

Alfred Legerton, 5, Aldgate, London.—*Wholesale Catalogue of Dutch and other Flower Roots.*

Joseph Schwartz, Rue de Repos, 43, à la Guillotière, Lyon (Rhône).—*Catalogue of Roses.*

John Jeffries & Sons, Cirencester.—*Select List of Dutch Flower Roots.*

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

ADDRESS (H. J. A.).—We cannot state the address of any correspondent who prefers to write anonymously.

PEAR CRACKED (J. Hamilton).—This is caused either by exposure to cutting east winds when the fruit is in its earliest stages of growth and the skin is very tender, or else there is fungoid growth on the fruit; in the latter case the leaves would be also attacked. Sulphur is the only remedy we know for attacks of this nature. It would have to be applied early in the season to do any good. We would mix  $\frac{1}{2}$  lb. of sulphur and 8 ozs. of soft soap in a gallon of rain water, and apply it to the trees with a syringe. We do not say this will effect a cure, but it is worth a trial.

CELERY LEAVES GRUB-EATEN (T. J. B.).—The grubs are the offspring of the Celery Fly, *Tephritis opordordina*. Mr. Westwood suggested that to prevent the grubs the parents might be caught by strings smeared with bird-lime stretched over the Celery rows. Pick off the affected leaves and destroy them; to do so would not be very time-consuming.

DRESSING FOR VINE BORDER (G. G.).—Remove the top soil down to the roots, but without injuring them, and replace with sound turfy loam mixed with inch bones at the rate of 2 bushels of bones to a cartload of soil, and surface the border with a covering of good manure. Do it at once.

BUDDED ROSES (Idem).—Remove the ties at once. We should not stop the shoots which have pushed, but should let them grow, and cut them close in at the winter's pruning; that will also be the proper time to shorten the Briar stems back to the buds.

DAYING COCKSCOMBS (H. G.).—There is no process that we know only to hang them up in a dry warm room, but the combs will not retain their colour as they are too fleshy to dry well.

MYATT'S SEEDLING STRAWBERRY (Idem).—It is a fine late kind, and usually very prolific, doing well in light soils where British Queen does, and is usually known as "Filbert Pine."

CUTTINGS OF *CALCEOLARIAS* (Drake).—By reducing the flowering parts you will further the formation of shoots from the base of the plants, and these or any shoots not showing flower are eligible for cuttings. They should be put in before being frosted from the middle to the end of October.

SEPARATING POTATO SEED FROM THE PULP (Idem).—Reduce the "apple or crab" to a pulp, and this being washed in water the seeds will sink to the bottom; the pulp will swim or mingle with the water, and may be poured off. Continue the washing until the seed is thoroughly cleansed, and dry it before storing away in paper.

SOWING APPLE AND PEAR PIPS (Idem).—They may be sown now, but are better kept in a rather moist place thinly spread until February or March, or they may be kept in shallow boxes in dry sand in a cool place. They shrivel because the seeds are not well ripened, and by being kept in too dry a place.

THINNING PEACH SHOOTS (A. B. C.).—You will have sufficient young wood if the shoots are 6 to 8 inches apart, but we should limit the thinning to the old bare shoots or long bare branches, and to those which have fruited this season. If the shoots 18 inches to 3 feet long have triple buds at about 14 inches length you may shorten them to those, and safely, as in such a length there cannot fail to be wood buds, as well as at their extremities. It will not injure them for future fruiting, but be conducive thereto by admitting light and air to the parts left, thereby securing their more thorough ripening of the wood.

EUCALYPTUS—WINTERING CALADIUMS (A. B.).—We cannot tell what the *Eucalyptus* may be without some description. There are about fifty species. The *Caladium* roots should be wintered in the pots and be kept without water, but the pots placed on a moist bottom from which they will derive sufficient moisture to keep the roots from shrivelling, and the temperature in which they are kept should be that of a stove—not less than 55°.

TURKISH GROWING TALL (St. E.).—They are tall because kept at a great distance from the glass and therefore are drawn, but under any circumstances they grow tall. It appears you can grow and flower them, and yet you ask us to give their treatment. The "greenhouse" *Daphne* is treated of in the "Greenhouse Manual." You cannot have a more suitable Vine than the Black Hamburgh.

PINK OR ROSE-COLOURED ROSES (Midland Mule).—Baronne de Rothschild, Baronne Prévost, Charles Bonillard, Edward Morren, Louise Peyronny, Duchesse of Edinburgh, Comtesse de Chabillant, and La France.

FRUIT TREES FOR GARDEN (X. X. X.).—We presume you want pyramids or bushes. *Plums*.—Dessert: Golden Gage, Green Gage, and Transparent Gage. *Kitchen Plums*: Prince Englebert, Victoria, and Yellow Magnum Bonum. *Strawberries*: La Grosse Sucrée, Sir Joseph Paxton, President Lucas, Dr. Hogg, and Helena Gloede. *Pears*: Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Louise Bonne of Jersey, Beurré Hardy, Marie Louise, Thompson's, General Toddleban, Beurré Diel, Gloe Morcen, Beurré Bachelier, and Beurré d'Arenberg. They are named in the order of ripening, and not as to quality, for all are good. *Cherries*: Empress Eugénie, May Duke, Bigarreau, Bigarreau Napoleon, and Morello. *Damsons*: Cluster

or Crittenden, and White. *Desert Apples*: Red Astrachan, Kerry Pippin, Mother Apple, King of the Pippins, Cox's Orange Pippin, and Reimette du Canada. *Kitchen Apples*: Lord Suffield, Cox's Pomona, Blenheim Orange, Warner's King, Dunselow's Seedling, and Bedfordshire Foundling. *Nuts*: Osoford, Red Filbert, White Filbert, Dwarf Prolific, Prolific Cob. A Clematis would answer for covering the spot, and O. Jackmanni would suit.

**VENTILATING GREENHOUSE (Idem).**—For a greenhouse 20 feet by 10 feet you will need more than the 11-inch width of ventilation at the upper part of the house, which should not be less than 18 inches; and as for dispensing with front ventilation it is a mistake, as you cannot have too much of it in hot sunny days, and the iron gratings proposed in place of front ventilation will be inadequate. Every other—better every light of the front—should be made to open in addition to the top ventilation of the increased width named.

**DIVIDING AND PLANTING LILY OF THE VALLEY (W. H.).**—It may be done in November, or after the leaves are decayed, and in mild weather up to March.

**ONIONS BOTTING (Idem).**—We can only conjecture that they are affected by maggot, for which, after an attack, there is no remedy.

**GRAPES NOT RIPENING (W. M. Grose).**—The symptoms you describe are those of shanking, but it is rare that shrivelling is accompanied with mildew and rotting. It is likely that had the berries been more and earlier thinned, more foliage encouraged, and strict attention paid to stopping, along with more heat, and at the same time more air, you would have succeeded in ripening the Grapes more satisfactorily. Under the circumstances we should yet apply more heat, admitting air very freely, and so secure the thorough ripening of the wood, upon which in a great measure depend next year's prospects.

**TREATMENT OF TOXICOPELLEA SPOTAZULE AND OTHER STOVE PLANTS (A. W. G.).**—Toxicopelma spectabile is a warm greenhouse or cool stove plant, and is propagated by cuttings of the young half-ripened growths in sand in bottom heat under a bell-glass. Peat soil with a third of fibrous loam will grow it well, keeping moist at all times, and watering freely when in growth. *Franciscea* succeeds in a compost of equal parts fibrous loam, sandy peat, and leaf soil, with a free admixture of silver sand and good drainage. Cuttings of the young shoots after they become firm root well in sandy soil in bottom heat covered with a bell-glass. *Eranthemum pulchellum* is also a stove plant, doing well in fibrous loam, with a third of leaf soil, and cuttings of the young shoots strike freely in sandy soil in gentle bottom heat or without, but emit roots less speedily. *Streptelia juncea*, another stove plant, requires two parts fibrous loam, one part sandy peat, half a part leaf soil, and a sixth of silver sand and good drainage. It is propagated by suckers or dividing the plant, and requires to be kept very copiously watered when in growth, and kept rather dry when at rest. All require light and airy positions, and abundant atmospheric moisture when making fresh growth, and water when not growing to keep the foliage from flagging.

**PROPAGATING VIOLA PERFECTIO (S. P. P.).**—Select cuttings of 2 or 3 inches in length, which come directly from the base of the plants, inserting them in sandy soil in a cold frame, or in a sheltered position outdoors, and keeping moist and shaded until rooted, and when well rooted plant-out after hardening-off in a sheltered border about 8 inches apart, and in spring move with balls to where desired. The cuttings may be put in at the present time.

**BREEDING GERANIUMS (Idem).**—We cannot improve upon your selection—viz., Cornish, the best scarlet; Master Christine, the best pink; but Amaranth (Pearson) is very good. White Clipper is very much superior to Madame Vanouber, but of taller growth; the most profuse-flowering white is White Princess, and yet there is no really good white bedding variety.

**DESTROYING THRIPS (S. M.).**—Fumigate your greenhouse on two nights in succession, and each morning following syringe your Myrtle with soft soap water of a strength of 8 ozs. per gallon, and mixed with one-tenth of tobacco water. Apply the solution at a temperature of 130°. Repeat this in three weeks and you will eradicate the pest.

**POTTING FRACH AND NECTARINE TREES (W. B. A.).**—If you intend to pot the trees again in the same sized pots, reduce the balls, saving as many of the fibrous roots as possible. It ought to be done at once. See "Doings," page 255.

**VINES IN CUCUMBER HOUSE (A Subscriber).**—You may grow both together as you propose, the forcing not being begun until March, the Sweetwater succeeding under the same conditions as the Black Hamburgs. Strawberries would do fairly, they having a position about 15 inches from the glass. They ought to have been layered in small pots so soon as runners were obtainable, and potted by the middle or end of August into 6-inch pots. You may succeed fairly by now potting-up any strong plants into 7-inch pots, but neither the Vines nor Strawberries will do other than moderately well grown with Cucumbers, they being secondary to the latter. The Sweetwater Vine may be potted now.

**LIQUID MANURE FOR STRAWBERRIES.**—"OLD SUBSCRIBER" would add very much to the usefulness of his remarks by stating the composition and proportions of the ingredients in the 'ammonia water' and the 'lime water' which he speaks of.—A NOVICE.

**HEATING-POWER OF BOILER (C. C.).**—The size of the boiler is no criterion of the heating power, that depending upon the amount of surface exposed to the action of the fire. Your boiler will have about 8 feet of surface exposed to the action of the fire, which, without very hard stoking, will be sufficient to heat the 280 feet of 4-inch piping you propose attaching to it.

**STORING WALNUTS (D. O. J.).**—Remove the nuts from the husks, and if this be done at the ripening the nuts will turn out very clean, and store away in dry sand in a cellar or other cool place, and moist rather than dry, but not wet. They will keep in this way, or in stone jars stored in dry sand, for a lengthened period, but they will become more or less dried, and this, we think, you wish to avoid, and so do others, as the kernels in a dried state will not "peel," hence the nuts are kept in moist sand or soil to the deterioration of the quality or flavour, for in contact with moist soil or moisture they absorb it, and warmth being present growth must follow. By storing in dry sand, in a moist place and cool, we prevent any loss of flavour and arrest growth, whilst at the same time obviating the evils of over-drying; and though nuts so kept may not "peel," they may, by placing them for twenty-four or forty-eight hours in rain water, have the kernels restored to plumpness, peeling readily. The time of steeping is dependant upon the dryness of the nuts.

**EARLY AND LATE ROSE POTATOES (A Constant Reader).**—There is a great confounding of the "Early" with the "Late" varieties of this Potato. The former is of very indifferent quality as compared with the finest-quality kinds. It is not really good at any time, but improves by keeping, being

more mealy, and is best after November. Late Rose is much finer, and after Christmas good. Steam them in their skins after clean washing, and peel whilst very hot, just before sending to table.

**GLOXINIA LEAVES BUSTED (M. W., Cork).**—The leaf is rusted and destroyed by thrips, which might have been prevented by fumigation with tobacco, and growth encouraged by a moist atmosphere. To avoid its ravages in future afford the plants a moist atmosphere and a brisk heat, keeping moderately shaded and near the glass. The leaves for a good display of bloom should be nine times the size of the one sent us.

**PRINCE OF WALES CHRYSANTHEMUM LEAVES DISCOLOURED (Idem).**—It is constitutional and peculiar to this and a few other kinds, and more prevalent in a wet than a dry season, hence we conclude that it is remnant of overwatering or too high feeding. Very careful watering is necessary, not saturating, nor, on the other hand, allowing the foliage to flag through an insufficient supply. It also suffers in a close confined space; therefore, give plenty of space, and an open airy position.

**FRACH SHOOTS MILDEWED (Idem).**—The specimen sent is badly mildewed, the wood being green and very unripe. You have used "soapy water" and applied "sulphur." Perhaps so, but inefficiently. Syringe the trees thoroughly with a solution of soft soap, 2 ozs. to the gallon, and dust the parts effectually with sulphur from a dregger, and lift the trees so soon as the leaves commence falling, and make the soil very firm and moderately rich so as to induce stronger yet shorter-jointed and more fruitful wood, not allowing them to suffer by want of water at the root after the middle of June.

**COPING-BOARDS (C. P.).**—Mr. Lockhurst, who is a most successful cultivator, recommends inch boards to project at right angles 15 inches from the wall. He never removes them, at the same time it is advisable to so fix them that they can be taken down if required. These boards afford great protection from frost, and are valuable aids in assisting the ripening of the wood of the Peach trees.

**INSECTS ON SOLANUMS (K.).**—The leaves sent are infested with thrips and red spider. Syringe them with soft soap and tobacco water of the same strength as that recommended to "S. M.," applying it at a temperature of 100°. The solution must be applied forcibly to the under sides of the leaves, and the plants should be syringed daily afterwards with clear water.

**NAMES OF TREES (J. O.).**—1, *Pinus austriaca*; 2, *Pinus montezumae*.

**NAMES OF FRUITS (H. W., Penze).**—The Apple is New Hawthornden. (J. Woodlife).—Neither are Tower of Glamis; 1, quite rotten; 2, Wallington or Dunselow's Seedling; 3, Golden Noble. Pear rotten. (A Constant Reader).—3, Beurre d'Amanlis; 4, Beurre d'El; 2, Probably Vicar of Winkfield. Send the others again when ripe. (A Contributor, S. W.). 1, Beurre d'Amanlis; 2, Easter Beurre; 4, Beurre d'Arenberg; 2, not known. (L. Constant Reader).—3, White Doyenne; 4, Beurre Berkman; 5, Beurre de Capeman. (A. Ager).—2, Dunselow's Seedling; 4, Pomona; 5, Bedfordshire Foundling; 6, Blenheim Pippin.

**NAMES OF PLANTS (S. B.).**—*Glaucium luteum*, the yellow Horned Poppy. There is a portrait and full account of it in our "Wild Flowers," fig. 149. (T. W. Bague).—Leaf only. (B. L. D.).—*Fraxinus racemosa*. (Signe).—A species of *Fyrus*. (T. E.).—We cannot name from leaves. (M. H.).—1, *Chelone glabra*; 2, *Solidago Virgaurea*. (James Ferguson).—*Funkia orata*. (An Old Subscriber).—*Atriplex horrida*, which used to be much cultivated as a vegetable. (M. H. M.).—The Scarborough Lily, *Vallota purpurea*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### MICHAELMAS-DAY.

YESTERDAY (September 29th) was Michaelmas-day, and this is our Michaelmas number. The Geese have been slaughtered in *memoria*, and apple trees and the sage and onion beds have had inroads made upon them. This is all we can say here about the patron bird of Michaelmas, so we must turn to other topics connected with the world of which he is a member.

Three months ago to-day was Midsummer-day, and then we sighed of ourselves for ourselves as we saw the small ranks in the chicken runs, and knew what the summer shows could only produce under the circumstances. Our forebodings were correct, for now, taking a retrospect of the shows of those three months, we plainly see that it was a bad summer chicken season, and that very few produced birds of any note whatever.

Michaelmas is now here, and the autumn shows will commence, and with the new quarter we hope for and expect better things. Some of the classes at the late chicken exhibitions have been most wretchedly represented; but now a new quarter has dawned—

"When earth repays with golden sheaves  
The labours of the plough,  
And ripening fruits and forest leaves  
Are brighter on the bough."

Nottingham commences the new list, but that is not a regular chicken show; it is followed, however, by the Alexandra Palace and Oxford Exhibitions, where the *élite* of chickendom will doubtless be found, and then comes the other Palace, and then the full whirlwind of shows is upon us. We hope for well-filled classes in future, and to find the old names, which have been more or less absent of late, figuring well to the front. There has been time now to get over the woes of the early year, for by October everyone will surely have something good to exhibit. The summer chickens have had their day, and now exhibitors must buckle-to for a sharp contest, and produce fresh chickens from their *corps de reserve*, for those which have done battle through the summer will now in many cases have to make way for others. It is, of course, well known that those birds which are sent from show to show through the hot and trying summer months never do much good afterwards. Certainly some few

which are produced later in the summer, and are not so much knocked about, do live to be the glory of autumn and winter events, but we can call to mind but few specimens which promise to do so this season. A few of the best Cochins and Brahmas—we speak here of the large breeds—may again crop up in the prize lists, but we fancy we shall see in most classes at the forthcoming autumn and winter shows a perfect *bouleversement* among the late winners, and shall find old names with new birds to the front once more.

Let us take a retrospective look in this our Michaelmas number at the chickens of the past two months. We do not mean to individualise certain classes at certain shows, but take a brief peep of what has so far appeared. We doubt if any one chicken show can be called a real success, and at many the results have been positively calamitous. Mr. Watts's heart-rending epistle, to which we hope his patrons will turn their attention, speaks more graphically than ever we can do of the unfortunate *finale* of the one large chicken show which has been up to now held; but some shows have come off worse than others, and we fear the poultry department of Middleton, Wisbeach, and hosts more must, as far as entries are concerned, have experienced a great loss and heavy check to their ardour this last season. Dorkings have, perhaps, this year been better in quality than quantity. We have found nowhere the classes of the 1874 summer shows; but, on the other hand, no bird was then produced to equal the cup Birmingham and cup Bath bird of last month. In Dorkings of other colours we have seen one or two good Silver-Gray cockerels, but nothing in pullets, and nothing striking in Whites or Cuckoos. The summer Cochins, again, have been but sparsely found, and the winners have been mostly in the hands of one or two. Partridges have, perhaps, been the best, and there are one or two good chickens to be found. Of Whites there has positively been exhibited nothing worthy of remark if we except the winning cockerel and pullet at Aston Park. Brahmas have made the greatest mark, the Lights especially; but, then, "everyone keeps Brahmas," as a gentleman said to us at Bath the other day. Certainly their admirers are legion, and the classes have consequently more reason to be well filled. Two or three good Darks have been out, and will now, we suppose, be going in, for Mr. Ansell's cockerels have done him good service. The pullets have been pretty fair, but they have not had their usual size and shape. The Lights have been very good, still in them a few good birds stood clearly out; but both cockerels and pullets have made a most creditable appearance, and surpassed, perhaps, on the whole all other breeds. Spanish and Game have made small classes, and the chickens have been late specimens. We have not seen one Game chicken to really admire, and this time last year Mr. Matthew's Birmingham Duck-wing pullet was the talk of everyone. French have mustered well, Houdans especially, though Crêves have looked up latterly. Houdans are very precocious, and soon come on, maturing quickly, and are consequently useful birds for the early shows. We fancy for quality and quantity, as a lot, Houdans would come pretty high in an average list this summer of 1875. Hamburgs seem to have appeared in fair numbers in the north, but at the midland and southern shows have been badly represented; even such shows as Shrewsbury, with its panoply of prizes, produced but a sorry lot of entries. We hope better times are dawning, and that we shall find numbers as well as quality in future, for Hamburg people have not to secure weight or size, which are the stumbling-blocks to so many breeders of other varieties. We have seen a few good Polish chickens, among them some very promising White-crested Blacks; but we regret to hear we are losing from our poultry ranks one of the oldest admirers of this latter breed, and one who has done an immense deal to keep it from extinction in past years. Then in the Variety classes we can remember nothing worthy of remark except the Malays, whose supporters have sent to the front some splendid chickens. Minorcas, Leghorns, Silkies, and such unhappy denizens of the various refuges have been a moderate lot. We cannot help remarking, however, here on the immense trouble that Mr. Kitchen is taking to push his commodity, and we hope he will do so successfully, for we gather that Brown Leghorns are extremely hardy and very free layers at all seasons. Bantam chickens have not been a very gay lot; we almost think we give the palm to the Blacks, though we have seen a good pen or two of Seabrights; the Game, however, have been, as a lot, considering the great favour they hold and the extensive way they are bred, decidedly disappointing. Waterfowl, Turkeys, and Geese have been quite up to the mark, and in many cases superior to those of past seasons. It is satisfactory to end this peep at the summer's birds with something that has been a credit to the breeder and exhibitor in this trying season.

Thus much, then, for the chickens from Midsummer-day to Michaelmas. No doubt many breeders have yet to produce their birds, and others have fresh specimens to fall back upon. Anyhow, chickens good and valuable should now be plentiful; for, as we before said, the later-hatched birds have had time to

grow and develope, and we shall expect, consequently, from this Michaelmas-tide to find the classes well filled as in bygone seasons, and the whole poultry world once more back in their old places and in their old form.—W.

### OXFORD POULTRY SHOW SCHEDULE.

ANOTHER October is near at hand, and the Oxford Poultry Show for the fourth time is not far distant. The schedule is more tempting than ever, and this Show should even surpass all previous Shows. After the Palace perhaps no Show of late years has literally galloped into public favour like Oxford. This must be extremely satisfactory to the indefatigable Hon. Secretary Mr. King and his Committee, who have spared no money or labour to make their Poultry Show worthy of their city, which in so many points stands unique. It is quite refreshing to turn to the rules and read them. We find a wonderfully low entry fee—only 5s., with first prizes of 60s. or a 68s. cup. Several pens of birds may come in the same basket. The prize cards so valued by some, especially amateur beginners, will be forwarded on to the winners. The Judges are announced—viz., Messrs. Esquillant and Jones for Pigeons, and Messrs. Hewitt and Teebay for the poultry; and a very good rule as regards sales—viz., instead of an auction, which at so many places is a perfect failure, we find the sale office will be open for two hours to receive tenders, the highest, of course, securing the bird. We can all remember that the crack Dark Brahma pullet of last season was bought a bargain at a show where this rule was in use. The classes are for poultry fifty-one in number, and there are also in this department forty-one pieces of plate, or money may be taken instead if preferred. Among them we notice H.R.H. Prince Leopold again gives the Dorkings a champion cup. Local folks, too, must come well to the front at Oxford, for we find sixty-two local prizes and two local cups.

Looking over the various classes we find Dorkings have four classes, Cockerels four, Game six, and Hamburgs five, for a cockerel and pullet in each pen. Some of the classes have four prizes, such as Dorkings, Brahmas, Houdans, &c. Polands have two classes; we are glad to find one is for White-crested Blacks. We hope they will muster better than last year. They hardly deserved a class after last season's behaviour. Malays and Silkies have each a class, while Americans have two, one being for Brown Leghorns and one for Any other variety. Bantams are well provided for, and there is a class for Pheasants, which we hope will be well supported. Waterfowl are in high favour. Blacks and Calls have each a class; the former generally make such a beautiful show at Oxford, and we hope they will do so again this season. They are arranged always in the upper gallery, where the light is perfect. The Sale classes are well divided, and the prizes numerous and handsome.

Pigeons, too, seem to have a good friend in Mr. Salter, for here they have thirty-four classes, with three prizes in each class and fifteen pieces of plate. We shall expect to find the Town Hall as full or fuller than ever. The breeds are well divided up as to colours, for we even find two classes for Magpies. There are two classes for Carriers and one for Barbs hatched in 1875.

We cannot find one thing in this good schedule to find fault with, and we sincerely hope all fanciers will respond and make this Show as good as it deserves to be. We hear that full arrangements will be made for all the birds that come on from the Alexandra Palace being well fed, kept in clean pens, and provided with green food till the Judges come round: consequently all who have entered at the Alexandra can with confidence enter here also and have their birds sent on direct, thus saving carriage and labour. Mr. King will, we hear, be ready at Oxford to receive all such birds on Friday and Saturday, and both he and his Committee will personally superintend their being unpacked and well seen to. We cannot help saying that we are very glad to find these two good Shows ready and pleased to work together, for we have heard the kind expressions of Messrs. Nicholls and Jones on the matter. The entries close on October 9th, and we would remind our readers that at Oxford entries do really close on the day they name, and that no "acts of grace" are there given.—W.

### AYLESBURY POULTRY SHOW.

AYLESBURY is always a pleasant little meeting. The Show is nicely arranged, and the covered meat market makes a most excellent place for the Exhibition. We always find good birds here, for the Show is only for one day, and the prizes very liberal, consequently exhibitors do not mind sending good specimens. They are very prompt here, too, with the catalogues, sending them out as quickly as possible, and the Aylesbury Show of 1875 has proved no exception to other years. The entries were not quite so numerous as last season, but then other shows were being held in other places on the same day, which of course must make some of them weak in their classes.

Dorkings all competed together, and came first in the cata-

logue. There were nine pens. We did not fancy the quality was quite equal to the usual style here, but the cup pen were a fine pair all round. *Brahmas*, too, were classed together. We generally find a good pen or two from Stoke Park at this Show, Mr. Wragg making it his "opening day;" but this year Lady Gwydyr's name is not in the catalogue. The cup pen was a grand pen of chickens, the cockerel especially good and large. The winning Lights, too, were good; but we hope next year to find *Brahmas* having two classes. *Spanish* made a fine class. It is quite pleasant to tell of fifteen pens being entered in one class when Long Sutton only mustered three pens in two classes with six prizes. A very good pair of adults won the cup, being large in face and good in combs: second went also to very nice old birds; while a promising pen of chickens took the third place; 96 (Mills), a nice pen of chickens, and so was the same exhibitor's pen 27, but the latter were younger birds. *Cochins* had three classes. The Buffs made the largest class, and Whites next. In Buffs a splendid pair of chickens won the cup; second also a promising pair of birds; third only middling. We thought there were two or three other pens here well worthy of notice. Partridges were very fine, the winners all good; the first chickens really splendid, and we almost thought the *Cochin* cup should have come here, the cockerel being such a beauty. Whites were a good lot; all the prizes were won by adults. Mr. Fowler sent a good pen of chickens in this class. *Games* had only one class, and consequently only six entries were made. A very well-shown pair of Duckwings of fine colour won the cup. Here, again, we recommend next year another class being made; exhibitors will not send in a general class of any colour. *French* made a fine collection, and we thought the prizes fairly awarded; the Crêves were especially good. *Hamburgs* had two classes, and the quality was first-class. A splendid pen of Silver-pencils won the cup; second going to good Golden. Spangles were very nice, one or two of the Golden cockerels being especially good in markings and points. *Americans* had a class, and came seven pens strong. A beautiful pen of White Leghorns won the cup; second also going to nice White chickens; 89 (Kitchen), neat Brown Leghorns; 94 (Fowler) Plymouth Rocks. Game *Bantams* had but one class and five entries. They evidently resented this insult of having but one class as much as their larger relations. The quality was fair. The Variety Bantam class were six pens in number. Nice Blacks first and third; and fair Golden-laced second; 106 (Cambridge), good Blacks. The Variety class was excellent. Polands were the best; the first-prize birds being very grand.

Aylesbury Ducks were not as strong in numbers as we should have expected in this their own birthplace. Mr. Fowler was well to the front with two noble pens, and once more kept-up the honour of his town. Rouens also were very good, and the quality even. In variety Ducks Mr. H. B. Smith cleared the lot with nice fancy birds. For Lady de Rothschild's £5 5s. cup for best pen of Aylesburys under certain conditions, only four pens appeared. A nice pen secured the cup, and the others were good, but we certainly expected to find more competition for this piece of plate. Geese were good, but again only four pens in number. The quality was, however, excellent, and all noticed. We were surprised to find no class for Turkeys here. Being a branch of an agricultural show, surely Turkeys should have a chance of distinguishing themselves, though we are afraid they do not often do it, judging from the few entries we have of late seen in the Turkey classes. The Sale class was large. The price per pen was limited to 80s., nevertheless many of the birds were very fair specimens, and an extra prize was awarded.

Mr. M. Leno was the Judge, and his awards gave satisfaction. We publish full prize list below.

**DORKINGS**.—Cup, Rev. E. Bartram, Barchampstead. 2, J. Taylor, Dorking. 3, J. Gee, Oxford. Ac, E. Woodford, Kidlington.

**BRAMMAS**.—Cup, H. Lingwood, Cressing. 2, Mrs. A. Tindal, Aylesbury. 3, J. Long, Bromley Common. c, E. Kendrick, jun., Lichfield; J. K. Fowler, Aylesbury.

**SPANISH**.—Cup, R. Wright, Holloway Road, London. 2 and 3, D. M. Mills, Newport Pagnell. 3, W. Notage, Northampton. Ac, H. Beldon, Goltstock; Mrs. Allsopp, Worcester. D. M. Mills; Mr. Allsopp.

**COCHINS**.—Buff.—1, Mrs. Tindal. 2, A. Darby, Little Ness. 3, E. Winwood, Worcester. c, Mrs. Allsopp. Partridge.—1 and 2, Mrs. Tindal. 3, J. K. Fowler. White.—1 and 2, Capt. G. F. Talbot, Eden Bridge. 3, C. Bloodworth, Gt. Eltham. Ac, Mrs. A. Tindal. c, J. K. Fowler.

**GAMES**.—Cup and 2, S. B. Mathew, Stowmarket. 4, H. E. Martin, Sculthorpe. Ac, E. Winwood. c, G. E. Fisherbert, Sevenoaks.

**FRENCH**.—1, H. Feast, Swansea. 2, J. K. Fowler. 3, E. Burrell, Farrington. Ac, W. Dring, Faversham. c, W. Cusack, Littleport.

**HAMBURGERS**.—Gold or Silver-pencilled.—1, E. Beldon. 2, J. Robinson, Garstang. 3, C. Judson, Peckham. Ac, H. Beldon. 3, Carr, Swansea. Gold or Silver-spangled.—1, H. Beldon. 2, J. Robinson. 3, J. Long. Ac, J. Long; J. Carr.

**AMERICAN FOWLS**.—Cup and 2, J. K. Fowler (White Leghorns). 2, E. Burrell (White Leghorns). c, E. Kites, Wetherham; A. Ward, Wimpole Street, London; J. K. Fowler (Plymouth Rocks).

**BANTAMS**.—Game.—1, E. Winwood. 2, W. Adams, Ipswich. 3, A. Darby. Any other variety.—1, W. K. Shackleton, Bradford. 2, E. Pritchard, Tettenhall, Wolverhampton. 3, H. Beldon.

**ANY OTHER DISTINCT VARIETY**.—1 and 2, H. Beldon. 3, A. Darby. Ac, J. Robinson.

**DUCKS**.—Aylesbury.—Cup and 2, J. K. Fowler. 3, J. Hodges, Aylesbury. 2, T. Kingsley, Aylesbury. Rouen.—1 and 2, W. Evans, Freetown. 3, J. G. Ac, Mrs. Badelyle, Hyde. c, E. Woodford. Any other variety.—Cup, 2, and 3,

H. B. Smith, Broughton, Preston. 3, J. Walker, Rochdale; W. Boucher, Lancaster Road, London. Ac, J. Walker; W. Boucher. Aylesbury.—Cup, W. Roberts, Long Marston. Ac, Mrs. E. Marshall, Canagana, St. Day. c, F. Payne, jun., Aylesbury.

**GRAYS**.—1 and 2, J. K. Fowler. 3, Mrs. Badelyle. Ac, T. Kingsley. **SILVER-GREY**.—1, Mrs. A. Tindal. 2, J. Hodges. 3, G. Bentley. Extra 2, W. Weston, Aylesbury. Ac, W. Botton, Aylesbury; Mrs. Allsopp; W. Clarke, Aylesbury; J. K. Fowler. c, Mrs. Allsopp; J. K. Fowler.

## LONG SUTTON POULTRY SHOW.

This was held on the 22nd and 23rd inst. The entries this year were not in numbers as good as usual, but the quality was quite up to the mark. We miss many familiar names in the catalogue, but suppose that other shows nearer home kept the birds away. It seems to us a remarkable thing that committees will allow their shows to clash so much, for last year Aylesbury and Long Sutton held their shows on the same days, and we should have thought they would have learnt better. We notice ten days to spare in October before the Alexandra Palace when there is no exhibition to be held, and we should recommend some society which has hitherto clashed with another, and so damaged the interests of both, seizing upon this date at once, for it will soon be snapped-up. Dates of shows in these days must be fixed early and advertised continually if success is desired in the number of entries. The Polish classes have disappeared this year, and possibly this was the cause of the absence of our Yorkshire friends. The Show was nicely managed, and the pens of Turner's were well arranged. Mr. Helliwell, jun., looked after the birds, and kept to his duties well. Mr. Teebay awarded the poultry prizes, and Capt. Heaton those of the Pigeons, and both gentlemen performed their parts in a satisfactory way.

The first class was for *Dorking* cocks or cockerels, but only two entries were made, and of them a good Coloured cockerel was the winner. In *Dorking* hens a very fine Silver-Grey came in between two splendid Coloured birds, and they made a beautiful trio. *Cochins* were small classes; the quality was, however, good. In Buff cockerels the winner was a well-grown bird of even colour; second and third also good. In the other Buff class fine pullets were first and second, third going to a fair old hen. Partridges were good, the first cockerel especially so. In the other *Cochin* classes most of the prizes went to the Whites. The first cockerel was smart and nice in shape; second a very promising bird, but as yet unfurnished, lately come from Pembury we believe; and third a Black. White hens were very good and nicely shown. Dark *Brahmas* were capital. A beautiful cockerel with much style and feathering won first, while the same exhibitor's grand hen landed him the extra of this section; the second went to a well-marked pullet, but not enough "unhatched" for our taste. Only four Light cocks were entered. Of them the winner was a good chicken of great promise. In hens a grand old bird was first; she was beautiful all round, and must be one of the Quenborough lot we should think; second went to a very pretty pullet. *Hamburgs* mustered miserably: only six pens of Spangles for six prizes! This is easy winning with a vengeance; but the quality of this half-dozen was very good, and they deserved their places. Pencilled, too, were poor classes in numbers. A nice Gold won the extra, but the winning Golden-spangled must have been close on him for this honour. The Pencilled pullets were good, all being of the Golden variety. The first pullet was clear in markings and generally good. *Games* were very weak in quantity, the quality being good. Only sixteen entries were made for twelve prizes; the extra went to a splendid Duckwing, good in carriage and head. The Black Reds were very fair. A good Brown Red pullet won in the other hen class, nice Piles taking the other two places. *Spanish* made the worst exhibition of the lot. We were fairly amazed to see only three pens competing for six prizes! The winners were fair specimens. *French* were very good—in fact, almost the two best classes in the Show, fifteen out of seventeen birds coming in for notices. In the cocks Crêves won all the prizes, and so they did in the hens, and it was something to win in such company. Brown *Leghorns* had a dozen entries; most of them were chickens. Had there not been an American class also at Aylesbury on the same day the muster would doubtless have been even better. Mr. Kitchen's were nice birds and well shown. The seconds were also neat chickens. The Variety classes were small. In cocks a Malay, Black *Hamburg*, and Poland won in the order named, a splendid Golden Poland hen winning also in next class and taking the extra. *Bantams* were beautiful classes, and, in fact, were the best part of the Show. A very stylish Black Red cockerel won the Bantam extra. In the other cock class a smart Pile came in first; second also went to a nice specimen of this colour. The hen classes were very good. A beautiful Brown Red won first, second going to a neat Pile, and third a pretty Duckwing. Black *Bantams* were good. In the Variety class Mr. Leno's Silver-laced again won him first, a good White-booted bird being second, and White Rose-combs third. *Water-fowl* were grand classes. The Rouens simply splendid, no less than nine pens coming in for notices deservedly. The extra went to a well-grown pair of Aylesbury ducklings. Every

Any other colour.—1, A. & W. H. Silvester. 2, H. Yardley. 3c, A. & W. H. Silvester; R. Fulton.

Mason (Himalayan); E. Frost (Grey-and-white Lop). 4, C. King (Silver-Grey); W. Kirby (Yellow-and-white); P. Booth (Sandy-and-white).

### ALTRINCHAM SHOW OF POULTRY, &c.

THE fourteenth annual Show was held on the 22nd and 23rd inst. The schedule for poultry is a good one, and in consequence the entries were good—about three hundred in all—the whole, except Turkeys, Geese, and Ducks, being for young birds; the whole of the above-named being very good, the Rouens a large good class, and the cup awarded to them.

Spanish cockerels were a good class, but several of the best-looking rather flat. Pullets better than the cockerels; but only five entries. In Black-breasted Red Game some of the otherwise best were sadly duck-clawed, especially the pullets. Brown Reds were better. In cockerels a smart forward bird was first; the second, a dubbed bird, had a fine head, but would have been better uncut for a while longer. There were some very young birds of great promise. Pullets a good class. In cockerels of any other breed Piles were first and second, and a Duckwing third; the whole very good, the first being a grand bird, but as yet quite unfurnished. In pullets Duckwings were first and second, and a Pile third; the first a grand bird of good colour. Dorking cockerels a fair lot, but the first-prize bird very rough-legged. Pullets, first and second Dark, and third Silver-Grey; a fair lot. Cochins, Buff, only four entries, but these very good, and the cup for Cochins awarded here. Pullets very good and high in colour. In any other colour cockerels Partridge won the prize; and in the next class the first and third were Partridge, and second White, the first a pullet with such pencilling as has never been seen before, but a little short of leg-feather; a large and good class. In Brahma cockerels the winners were well-known birds of previous successes. Pullets a large class, and many good birds; the first a grand bird, splendid in pencilling; second the Birmingham cup pullet, showing a little short in breast-marking; and third a good bird. In Hamburgs the entries were not large, but in some of the classes the Spangles of both colours by far the best, although there were some good ones in the Pencils, particularly the Gold-pencil cockerel and pullet, first-prize winners. There was no class for Black Hamburgs. French fowls produced some good birds, the first-prize Crève pullet being one of the best ever seen. The Polish fowls were much better than we have seen at any other show this season. The winners were Golden. Game Bantams had six classes, and all other varieties only one; but we would strongly advise that the latter class be divided, when there is no doubt but that the entries will amply repay that course. In Black Red cockerels the first was a grand stylish bird; the second also good was not in as fine order, but we did not consider the pullets equal to these. Brown Reds were very good, the pullets especially; in the latter our choice was with the third-prize bird, which had a most perfectly laced breast. In cockerels, any other, the winners were Piles, the third had yellow legs; but in pullets the first was a Pile, and second and third Duckwings. In the Any other variety of Bantams a silver cup was offered by Mr. Townson, the well-known amateur in Pigeons, the result being a fair entry, but of such quality as we have not seen this season, almost every pen being good enough to win such a prize, which was, however, awarded to a pen of Silver Sebrights rather large but most excellent in lacing; the second and third being Black. In the Variety class Black Hamburgs won the prizes.

Pigeons were under a very good marquee, and the pens were from Messrs. Turner, the poultry being in the open field in the pens of the Society.

The collection of Pigeons was of such quality as is rarely seen together in a field show, the classes being also well supported in numbers, and these were well attended to with food and water; but we would draw attention to the system adopted by some

ALTRINCHAM. G. H. SHUTTLEWORTH.  
Toucan.—1, R. Fulton. 2, R. Fulton. 3c, A. & W. H. Silvester, Sheffeld.

exhibitors of feeding with some special mixed food before the arbitrations are made. This was the case here with one exhibitor, no doubt thoughtlessly, but this being about one of the best studs shown it might have served as a point for some ill-natured remarks by ill-disposed people, and after a few classes had been judged the whole were swept clean, and in future we would recommend all such to be disqualified. A silver cup, value £5, was offered by Mr. Crabtree for the best bird in the Show, and was won by one of the most perfect White Owl cocks we have ever seen, closely pressed however by a grand Black Pied Pouter, which lost only through a little dulness of colour. Carriers were a good class—first a smart stylish Dun hen, and second a Dun cock, good in all points but eye, which is rather small as compared with the beak wattle; very highly commended a very heavy Black hen, which in high condition must come to the front. In Pouters the above-named Black was first, and second a good Blue cock. A White, highly commended, was grand but a little flat; most of the others were deservedly noticed. Barbs very good, but many in the moult. First a Black, and second Red, and very highly commended Black. All cocks. Tumblers, Almonds good, the winners very well spangled and good in head; the highly commended birds too dark, but otherwise good. In Tumblers, Any other variety, first a Yellow Agate, and second a Red Bald. The class good. Dragons were a large class, the first going to a Silver hen of great quality and black bars, second to a young Silver hen, and extra second to a capital Blue. English Owls were a good class, and the winners in grand order. First a Blue, and second and extra second Silvers. Pen 1529, a grand Blue, but dull in eye. As before stated, the first in foreign Owls won the cup for the best bird in the Show; the second in this class was also White, and all the others noticed. Jacobins were not good as a class, though the winning Reds were very good. Turbits were a real good class, the first a Silver cock, and second a Red, an extra second being awarded to a capital Black. Fantails were mostly noticed, and the winners White. Antwerps were a fair class, the first going to a Silver Dun cock, grand in colour and Antwerp points, but a little wanting on top of beak; second going to a well-known Red Chequer, deep in moult; very highly commended a Silver Dun cock, a previous cup-winner, but now bad in eye and grizzly in colour. In the Variety class, which by the way was not as good as we expected to find it, the first went to a Blondinette, and second to a Black Trumpeter cock of the old style. The Selling class was large, the first going to a Black Carrier cock, and second to a young White Pouter, the third being a Blue English Owl.

For Rabbits there were six classes, but no extras, and the entries fifty in number. Lops had one class, the first going to a Fawn-and-white buck, 23½ by 4½ ins.; the second a Fawn doe, was 21½ by 4½ ins.; highly commended a Sooty Fawn doe, swarming with fleas. Angoras a smart lot, the winners very good in fur. Himalayans were a poor lot, the winners only being of any note. Dutch bad, except the first, a Yellow; and one Rabbit in this class was very bad of scurvy, and ought not to have been sent. In Silver-Greys the first was in splendid order and grand in colour, but a little shaded on head; second a good Rabbit, rather light but in deep moult. In the Variety class the winners were Belgian Hares, the first very good in fur but small.

At future shows we would advise that the Rabbits be accommodated with room in the tent.

#### OSWESTRY POULTRY SHOW.

As the district around Oswestry is noted for supplying immense quantities of poultry for table purposes to Manchester, Birmingham, and a few other large towns, it is customary to find some of the best of specimens exhibited at its annual Show. This year not only were the entries more than customary, but the quality was fully equal to all previous shows. This neighbourhood has supplied many of the finest exhibition Game fowls that were ever shown, and exceedingly high prices have been occasionally obtained for the choicest specimens, causing an amount of care and attention to be paid to the breeding of such Game fowls that is not generally carried out in other localities.

Black Reds and Brown Reds appear to be the favourite varieties, and for colour and character few could match them. The Black Reds were shown in pens enjoying a capital light, and they thus became objects of public interest. The Brown Reds, though by no means less praiseworthy, were arranged in the lower tier, and most unfortunately in a position as regards light

that necessitated taking every separate bird in hand to form even an opinion of their colour when judging, and prevented the exquisite feathering of the "starling-breasted" cocks being seen at all by visitors. This arose entirely from the light from the roof (the only one) falling directly on the tops of the pens, but another season we are assured this mistake will be carefully avoided. The Duckwings were very perfect in feather, and the Red Piles were shown in no less fine condition. In *Dorkings* all colours competed together, first-rate Dark Greys being in the highest position, but very closely pressed by one of the best pair of White Dorking chickens we have seen of this season. Mr. Sidgwick had possession of the whole class for Partridge *Cochin* cockerels, his two entries being the only ones. They were, as they always are, hard to beat, even had the competition been by the score. Mrs. Allsopp was the winner with a grand pair of Buff *Cochin* chickens, which were in admirable show trim. In Dark *Brahmas* Mr. Ansdell, and in Lights Mr. Dean, quite upheld their notoriety in their respective classes to the entire exclusion of all opponents. The *Spanish* were remarkably good, and very fine well-grown chickens throughout. The *Hamburgs* were fine classes of every variety, and by far superior to former Oswestry shows. In Game *Bantams* the first-prize Black Beds and the second Red Piles were perfection both as to size, health, and colour. Rouen *Ducks* and also Aylesbury *Ducks* were so far beyond those previously shown as to qualify that they became the most admired of any of the Waterfowls, though remarkably fine Embden and Toulouse *Geeses* formed large and well-competing classes. Among the fancy *Waterfowls* a fine pen of *Autumnalis* Whistling *Ducks* and a pen of very choice White *Decoy Ducks* were the successful ones. As to the latter they were remarkably perfect as to form of head and shortness of beak, but, as is always of late years, far too large in body to compare with those of some thirty years back, when "Decoy Ducks" were oftentimes seen but little larger than Teal. Wet weather was a drawback throughout the day.

latter taking the onp for the best pen in the Show. The *Hamburg* classes all contained some first-class birds. *Ducks* and *Geeses* were very good classes.

The *Pigeon* classes were mostly well filled, and some choice birds were amongst them. The *Owls*, *Dragoons*, and *Antwerps* were all large classes, and very good.

Mr. James Dixon, Bradford, and Mr. James Fielden, Rossendale, were the Judges.

#### WETHERBY SHOW OF POULTRY, &c.

This was held on the 24th inst. The weather was unfortunately very wet, and the day a most comfortable one. This, with the severe illness of the energetic Secretary, Mr. Kell, caused many empty pens, which we do not usually find at such exhibitions.

*Geeses* were the first on the list, a grand pen of White geoslings taking first position. *Ducks* next these, and the ducklings being very good; Rouens being first in old birds and Aylesburys second. In *Cochins* out of seven entries only one put in appearance, and these were Bufts; but in chickens Bufts were first and Whites second. *Spanish* good, but in the moult. *Dorkings* moderate in both classes. The *Polish*, which were Golden, of fair quality. *Hamburgs* were but moderate, with the exception of Gold spangles, which were very good. In pairs of chickens of any distinct breed the first were capital Light *Brahmas*, and second Gold-pencil chickens. The *Bantams* in most classes being of fair quality, the first-prize Black Red chickens very good.

For *Pigeons* there was but one class, but the prizes were awarded in duplicate; the first and extra first going to Ios and Dragoons, second and extra second to Almonds and Carriers, and the thirds to Trumpeters and Jacobins.

For *Rabbits* there was one class, the first going to a pair of Angoras, one of which was very good in every respect; the second a pair of Fawn Lops, and third to Belgian Hares.

**GEES.**—1, O. A. Young, Driffield. 2, J. Simpson.

The Judge was Mr. Hutton.

**THE ALEXANDRA PALACE POULTRY SHOW.**—Captain Henton has kindly consented to act as one of the Pigeon Judges in addition to those gentlemen whose names appear in the schedule.

## NORWICH AND NORFOLK ORNITHOLOGICAL SOCIETY'S BIRD SHOW.

The first great annual Exhibition of Canaries, Mules, and British and foreign Cage Birds under distinguished patronage took place at the Victoria Hall, Norwich, on the 24th, 25th, and 26th inst. In every respect the Show was the best held this season. Three silver cups were awarded. Messrs. Mackley of Norwich winning two of them, and Mr. Thackrey of Bradford the third. We shall continue our remarks next week.

COCKATOOS.—1, J. Drake. 2, M. Gedga. 3, J. Hart, Norwich.

ANY OTHER VARIETY.—1, W. Walters (Norwich).

Messrs. Blakston and Copeman were the Judges.

## HINCKLEY SHOW OF CAGE BIRDS, &c.

On the 21st of September a very good Show was held at the Mineral Bath Grounds, Hinckley, situated some few miles from Leicester. The Exhibition comprised Canaries and other cage birds, besides Rabbits and Cats. The rain which fell plentifully somewhat damped the affair, and was anything but suitable to the Rabbits and Cats, which were shown openly, whilst the birds were more protected beneath an open and capacious tent. The entries in the whole were upwards of 230, the greater portion of them being for birds. Several exhibitors of some pretensions put in appearance, but most of the principal prizes in the Canary classes fell to the lot of Mr. Adams of Coventry, who exhibited fifteen specimens mostly peppered. The other most successful competitors were Messrs. Bunting of Derby; Athervuch, Coventry; Goode, Leicester; Coldnew, Burton; and R. Whitaker of Darley, near Derby.

The show of Belgian birds was poor. Norwich good, the classes being well patronised. Crested birds beyond average quality, and must have taken a little sorting-out. Cinnamon birds not quite so plentiful, but rich in colour. Lizard birds exceedingly good. Mules first-class. The British and Foreign classes fairly represented considering the time of year, but the moulting season apparently is a favourable one for birds. In the local classes for cage birds there were about fifty entries, but there was nothing of an extra kind shown. The class for British birds was the best supported, there being fourteen entries.

RABBITS numbered three classes in the All-England part of the Show—namely, Lop-eared, Any other variety, and Heaviest. There were sixteen entries in the first class, fifteen in the next, and two for heaviest. The chief winners were W. H. Crewe, Esq., Etwell; and Messrs. Woods, Mann, Clew, Barrows, and Robinson. For the heaviest Rabbit, W. Kirby was awarded a second prize, the first being withheld owing to the want of sufficient competition. Local exhibitors made a score entries.

CATS.—There were about thirty Cats and kittens shown, but in some of the classes the first prizes were withheld for want of competition. In Class 19, heaviest Cat, only two entries were effected, one of which was that of Mr. Minton's white short-haired English Cat, the winner of first prize at the Crystal Palace, Birmingham, Hanley, Boston, and Burton-on-Trent. With all these honours surrounding it, we think a first prize might have been given at Hinckley; had the Cat not been qualified for so distinguished a position, it would have made all the difference. The following is a list of the awards:—

BELOIANS.—1, W. Stringer, Altherstone. 2, T. Moore, Thringstone. 3, E. Arnold, Hinckley.

NOVICH.—1, Clear Yellow.—1 and 2, J. Adams, Coventry. 3, R. Whitaker, Darley. *Ad. G. E. Russell, Brierley Hill. c. C. J. Salt, Burton; J. Athervuch, Coventry. Clear Buff.*—1 and 2, J. Adams. 3 and 4, J. Athervuch, c. R. Whitaker. *Marked or Variegated, Yellow or Buff.*—1, 2, and 3, J. Adams. 4, J. Athervuch. c. R. Whitaker; G. E. Russell. *Crested.*—1 and 2, J. Adams. 3, J. Goode, Hinckley. 4, R. Whitaker. c. W. Sowry, Leek; C. J. Salt.

CINNAMON.—Yellow or Buff.—1, 2, and 3, J. Adams. 4, T. Coldnew, Burton. *LIZARDS.*—Gold or Silver-spangled.—1, J. Athervuch. 2 and 3, R. Bunting, Derby. *Ad. J. Adams.*

MULES.—Any variety.—1 and 2, R. Bunting. 3, J. Goode. 4, W. Tinson, Leicester. c. G. E. Russell.

BRITISH BIRDS.—Any variety.—1, T. Coldnew. 2, O. F. Foxon, Lutterworth. 3, J. Lacey, Burton-on-Trent. *Ad. R. Pearson, Whitby.*

FOREIGN BIRDS.—Any variety.—1, R. Bunting (King Parrot). 2, J. Goode (Parrot). 3, R. Bentley, Earlsdon. 4, Miss Robinson, Hinckley (Bengal Parrot). c. E. Arnold; W. Rowbottom, Naffstone (Grey Parrot).

SIX CANARIES IN ONE CAGE.—1, J. Adams. 2, C. J. Salt. 3, W. Stringer. *SELLING CLASS.*—1, J. Adams. 2, Martin & Griffin. 3, G. E. Russell. *Ad. R. Whitaker. c. Moore & Wyan, Northampton.*

### LOCAL CLASSES.

CANARIES.—Clear Yellow.—1, Clark, Hinckley. 2, G. Geary, Barwell. *Ad. W. Watts, Burbage. c. W. Young, Hinckley. Clear Buff.*—1, M. Malpas, Hinckley. 2, G. Geary. *Ad. W. Martin. c. W. Taylor, Hinckley. Marked or Variegated.*—1 and 2, G. Suffolk, Hinckley. *Ad. c. W. Taylor. Any other variety.*—1, G. Geary. 2 and 3, E. Arnold. c. W. Beane, Hinckley.

SIX CANARIES IN ONE CAGE.—1 and 2, G. Suffolk. 3, M. Malpas. c. T. Pinches, Hinckley.

MULES.—Any variety.—1, E. Arnold (Goldfinch Mule). 2, G. Suffolk (Linnæus Mule). *Ad. J. Taylor, Hinckley. c. A. Clark.*

BRITISH BIRDS.—Any variety.—1, G. Cockings, Earlsdon (Thrush). 2, W. S. Primmore, Hinckley. *Ad. J. Taylor. c. W. Hall.*

### RABBITS.

LOP-EARED.—1, E. Woods, Blackthorn. 2, J. Mann, Burton. 3, T. S. Barrows, Leicester. *Ad. c. W. Colley. Any other variety.*—1, W. H. Crewe, Etwell, Derby. 2, R. H. Clew, W. E. Robinson, Esq., Ad. E. K. Hinch, Humberstone, Leicester; T. S. Ludlow, Hinckley. c. J. E. Pilgrim, Hinckley. *Heaviest.*—3, W. Kirby, Ashby-de-la-Zouch.

LOCAL CLASSES.—Lop-eared.—1, G. Biddington, Hinckley. 2, R. Austin, Nuneaton. *Ad. G. Biddington. c. M. Malpas. Any other variety.*—1, R. E. Pilgrim, Hinckley. 2, J. E. Pilgrim. *Heaviest.*—1, A. Farndon, Hinckley. 2, E. Munton, Hinckley.

### CATS.

TORTOISESHELL.—1 and 2, Mrs. Jordan, Naffstone. 3, W. Kirby, Tabby. 4, E. Sherwin, Hinckley. *Any other colour.*—1, T. Coldnew. 2, G. Godfrey. 3, J. S. Pocock, Great Berkhampstead. *Heaviest.*—2, E. Minton, Newcastle-under-Lyme. *Cat and Kittens.*—1, Mrs. Pocock. 2, A. Maddocks.

LOCAL CLASSES.—Tortoiseshell.—1, J. Wells, Hinckley. 2, T. Truslove, Burbage. Tabby.—1, J. Baxter, Hinckley. 2, E. Colman, Hinckley. c. Miss R. Moore. *Any other colour.*—1, E. Lord, Hinckley. 2, T. Hunt, Hinckley.

1, 2, and 3, J. Adams.  
**CINNAMON.**—*Variegated Yellow.*—1, T. Tanniswood. 2, J. Thackrey. 3, W. and C. Berrington. c. J. Wilkinson. *Variegated Buff.*—1, J. Adams.  
**ANY OTHER VARIETY OF CANARY.**—1 and 2, J. Shickleton (Ticked and Yellow Buff Copy). 3, G. & J. Mackley (Ticked Buff Copy). *Ad. W. Evans (Ticked Buff Copy). Ad. L. Balk (Lancashire Copy).*

### MULES.

GOLDFINCH AND CANARY.—Clear or bono-Rds Ticked.—1, 2, and 3, and *etc.* R. Bunting. 4, G. & J. Mackley.

GOLDFINCH AND CANARY.—*Spangly-marked Yellow.*—1 and 2, G. & J. Mackley. 3, R. Hawman. *Evenly-marked Buff.*—1, J. Stevens. 2 and 3, G. & J. Mackley. 4 and 5, *etc.*—R. Bunting. *Ad. R. Pearson, Whitby.*

GOLDFINCH AND CANARY.—*Dark.*—1, G. & J. Mackley. 2, R. Bunting. 3, R. Hawman. *Ad. R. Bunting; G. & J. Mackley.*

LOVET.—1, J. Stevens. 2 and 3, G. & J. Mackley. *Ad. G. E. Russell, Brierley Hill.*

ANY OTHER VARIETY.—1 and 2, G. & J. Mackley. 3, R. Hawman (Greenfinch Canary). *Ad. J. Drake, Ipswich (Black and Canary).*

### GROUPS.

SIX NORWICH CANARIES.—*Irrespective of colour.*—1 and 2, Provart & Willis. 3, J. Yallop. *High colour, three Yellows and three Buffs.*—1 and 2, W. E. Novell. 3, J. Yallop. *Natural colour, three Yellows or three Buffs.*—1 and 2, W. J. Hutchinson, Norwich.

### BRITISH BIRDS.

GOLDFINCH.—1, Knight & Spencer, Baldock. 2, J. Drake. *Ad. J. Swain, Flocking.*

LOVET.—1, J. Drake. 2, R. Pearson.

REDPOLE OR SKIRK.—1, G. & J. Mackley. 2, C. E. Dade, Norwich.

SOME THREUP.—1, *Front, Norwich.* 2, F. Cullitt, Norwich. *Ad. C. Watson, Norwich.*

MAOPLE.—1, M. Athow, Norwich. 2, W. Parfitt, Norwich.

ANY OTHER VARIETY.—1, R. Humphrey, Harleston (White Blackbird). *Ad. J. Drake (Miniature Owl).*

### FOREIGN BIRDS.

WAX BILLS.—1, W. Walter, Winchester.

SPARROWS.—*Coral-necked.*—1, W. Walter.

PARAKEETS.—*Australian Grass.*—1, J. Drake. *Ring-necked or Indian.*—1, J. Barrow, Sunderland.

LOVE BIRDS.—1, J. Drake.

FARROTS.—*King.*—1, Miss Bateman, Norwich. *Ad. J. Drake. Grey.*—1, J. F. Bresse, Norwich. 2, J. Yallop. 3, Mrs. Elyth, Norwich.

Cat and Kittens.—1, A. Beale, Hinekey. 2, T. Pratt, Hinekey. Ac, J. Gunn, Hinekey.

JUDGE.—Mr. J. Bexson.

### JACOBINS.

I WAS much gratified to see that my letter on the above birds had called forth articles from the pens of such able and experienced fanciers as Mr. Harrison Weir and Mr. Huie, confirmatory of my remarks. That the birds known at present under that name are utterly worthless there cannot be a doubt in the minds of those who have seen the old type. What, then, can be done to bring about a better taste and restore the old bird to his proper position?

Mr. Weir's remark that judges will in general give prizes when the classes are filled, though there may not be a moderately good bird in the lot, has no doubt had something to do with bringing such trash into their present position. This certainly ought never to be the case when the professed object of societies and shows is to improve the breeds of our fancy birds.

If a class, however numerous, do not contain the requisite properties to a fair extent, then the prizes ought to be withheld entirely. This, I imagine, would soon bring forward something better.

The most hopeless aspect of the case, however, is, that many of the present judges hold that those named birds are the correct type. Some, no doubt, err from never having seen the genuine high-class birds. Were they to see them side by side, I believe no fancier with the slightest good taste could hesitate for a moment in deciding which was the high-bred bird; indeed, it would be easy to distinguish them in the dark.

If the fine old bird is to be placed in his proper place, I again say that it is time something should be done; but what to do and how, it is not so easy to say. Perhaps Mr. Weir or Mr. Huie may suggest some way of accomplishing this. I hope the matter will not be allowed to rest here.—Geo. Urr.

### LIZARD CANARIES.—No. 2.

In a former number of the Journal (page 147, No. 750) I drew attention to a first-prize Lizard, an excellent life-like illustration of which was given, representing a famous bird exhibited at the Palace Show by Mr. T. W. W. Fairbrass of Canterbury.

I like to be in the company of the "fancy," whether it be the humble artisan or one in more easy circumstances. Like birds of a feather fanciers will mix together. I often think there is an abundance of fraternity about Canary fanciers, although at intervals there may be jars and difference of opinion. It reminds me of birds passing through their periodical moult—they generally come all right and smooth in feather. During my little chit-chat with a brother fancier something of interest is sure to crop up, either about seed (that has been serious enough of late), cages, or birds.

The following remarks may perhaps not be uninteresting to those who have of late moved in Lizard circles. Nottingham Canary authorities (and I look upon Mr. Joseph Widdowson as one) have assured me that "the oldest Lizard breeder in England is old Sam Godbar, who has bred Lizards all his life." When I heard that remark two years ago I wondered how old the identical "Sam" was, and upon inquiry having ascertained that he had passed the age allotted to man, I knew not where to look for one who had devoted so much attention to a particular breed of the Canary. So far as the Canary cause generally is concerned I could mention the names of other veterans—for instance, Waller, London; Newsome, Bromley; Bond, Derby; but cannot positively assert that they, like "old Sam Godbar," have been in the fancy "all their lives." Finding myself in "old Sam's" company (during one of the very recent Nottingham bird shows) in a "little back parlour," where fanciers chose to discuss bird topics (it's no use disguising the fact), I was much interested in hearing him relate his knowledge of Lizards as they ought to be (but not with white eye-lids as once stated in a paper now defunct), the famous birds he had bred, and into whose hands they had afterwards passed, to win for their respective possessors laurels as their own "bona-fide specimens" at some of the best shows in England. "Old Sam's" ambition was more for breeding a good thing or two, and either selling them or exhibiting the same in his own locality, than sending them to distant shows. Previous to my personal acquaintance with the veteran Lizard breeder, I had for years previous heard it remarked that So-and-so's birds had a strain of "old Sam Godbar's breed in them." Yes, and if I do not mistake, I think that the famous prize Lizards exhibited by Isaac Stevenson (the miner, of Old Basford) at the Crystal Palace some years back, had some of the same strain in them.

In accordance with my promise I will devote a brief space to exhibitors of Lizard birds who have during the past few years been most successful upon the show stages. I have generally found that where any breeder and exhibitor has paid

particular attention to the breeding and the bringing of them out, greater success has resulted than would otherwise have been the case had that attention been but partly devoted to the same.

As some proof of what exhibitors have done, and the opportunity offered to others, I may state that during the season of 1874-5 Mr. Fairbrass won no less than thirty prizes (eleven first, nine second, and ten third) with his Lizards, besides twenty-two honourable mentions. With one exception the above is the greatest achievement I am aware of respecting Lizard Canaries in one season, and Mr. Fairbrass may be justly proud of his birds when he states in a letter to me, "I feel a pleasure in forwarding you an account of the number of prizes won." The exception alluded to was that of Mr. W. Watson, jun's, famous Lizards, which the same year and the season prior to the above won twenty-three first, twelve second, and eleven third prizes, the birds having been exhibited for the decision of the following ten judges: Messrs. Barnesby, Willmore, Moore (Fareham), Calvert, Tuckwood, Bexson, Moore & Wynn, Blakstone and Clarke of Sunderland. Without exception Mr. Watson's Silver-spangled Lizard cock was one of the finest birds ever exhibited of its class. Mr. Watson was the winner of numerous prizes, besides a silver medal for the best bird in five classes at Newcastle, a silver medal at Leeds, and a copper kettle at Darlington.

Instances are known of other breeders gaining more prizes with Norwich and other birds, but there is no comparison betwixt the Norwich and Lizard breeds, it being much more difficult to bring perfect-marked Lizards to the front than Clear Norwich birds. I have often thought it would be well to encourage exhibitors in exhibiting their own bred stock by offering prizes to the most successful exhibitors and breeders of various kinds of Canaries.

The following are the names of a few enthusiastic admirers who have at various times gained some repute as breeders or exhibitors of Lizards:—Williams & Tuckwood, Nottingham; Stevenson, Basford; Taylor & Stevens, Middlesbrough; Rev. V. Ward, Hythe; Ritchie, Darlington; Fairbrass, Canterbury; Ashton & Martin, Manchester; Belper, Derby; Hawkins and Judd, London; Watson, jun., Darlington; Reid, Halifax; Smith and Preen, Coventry; Mackley, Norwich; Bunting, Derby; Hayes, Sutton-in-Ashfield; Warren, Macclesfield, besides other numerous breeders in the neighbourhood of the last-mentioned town and in Lancashire and Yorkshire.—Geo. B. BARNESBY.

### BRITISH BEE-KEEPERS' ASSOCIATION.

#### CRYSTAL PALACE SHOW.

THIS Association held its second annual Exhibition on the 21st, 22nd, and 23rd inst.; and although we have had such an unprecedented bad season, a few magnificent supers of honey ornamented the show-tables. But it was amongst the hives and appurtenances that the value of the Association's labours was chiefly shown. The hives now shown were almost without exception good; inventors and makers had taken the lessons of last year well to heart, and adopting what they thought most useful, had in many instances added novelties of their own, which still further improved the whole. A very large attendance of bee-keepers gathered together and enthusiastically handled the exhibits, freely buying for patterns those they admired most. Nearly everything of value in the Show was claimed where a fancy price had not been asked. A prize was offered for the best collection of hives and bee-furniture. The first was awarded to Messrs. Neighbour & Sons, whose collection made a grand show of itself. Conspicuous among the hives was a large bunch of mallot clover standing 10 feet high! This plant is said to be highly attractive to bees, and is often sown for their exclusive use. Mr. Marriott, the Crystal Palace bee-master, had displayed his exhibits in a pretty attractive manner, but an almost entire absence of modern bar-frame hives precluded his winning second prize, which was awarded to Mr. Abbott, and an extra prize of equal merit to Mr. Lee.

In the class for observatory hives there was nothing novel, and the Judges evidently thought a second prize sufficient award to Messrs. Neighbour for their well-known Woodbury observatory. Mr. Marriott showed an observatory hive full of comb but no bees. This exhibit had much better have been away, as the comb was evidently infested with wax moths, and infested by foul brood. In Class 2, for the best moveable-comb hive for depriving purposes, the competition was very close, several exhibits showing points of excellence that their neighbours did not possess. The Judges had a difficult task before them, but they eventually awarded the first prize, a silver medal and £1, to No. 4, Mr. O. N. Abbott; and a bronze medal for second prize to Mr. J. M. Hooker for No. 13; Mr. Cheshire's hive of 1874 with some further improvements being passed over. Both the prizetakers had adopted many good points of Mr. Cheshire's hive, and to them added a multitude of contrivances of their own, which, especially in Mr. Abbott's case, in our opinion spoils the whole. Nothing is more essential in a hive than

simplicity, and nothing could be further from it than the first-prize hive. The method of securing the frames in position is a good instance of this fault. It is very difficult to describe without drawings, but we will say the ends of the top bars of the frames are cut pointed like the teeth of a saw, and these fit into corresponding spaces in the front and back of the hive. To release them, so that they can be removed, 1 inch of the front and back is hinged and folds outward, the bees will, no doubt, propolise every serration, and the consequent jar on its rupture will bring them angry to the top; every experienced bee-master must know there is nothing more essential than quietness in manipulation. On reclosing the hinged slips we are at a loss to see how the crushing of many bees is to be prevented. For the purpose of contracting the capacity of the hive the interior is fitted with a diaphragm of vulcanite. This is a useless additional expense, as wood would answer every purpose. No crown-board is used, but the frames are covered with a carpet, which is placed directly on the frames. We do not know whether bees can depend on a supply of propolis without limit, but as the insects never rest until they have closed every chink and cranny, we fear much energy will be expended which might be more profitably employed honey-gathering. There was one thing that particularly struck us—viz., Mr. Abbott in the pages of a contemporary has many times most strongly advocated the absence of a bottom rail to the frames, and yet in this hive we note its presence. In this class Mr. Rusbridge exhibited a hive which he calls the Sussex Hive; it is simply a Woodbury spoiled by the absence of a bottom rail. The slots in the crown-boards also are twice the width they should be for successfully keeping the queen from the super. Conspicuous in this class was the Sherrington hive, a good, substantial, rectangular straw hive, but with an absurd roof, large enough to require two men to remove it before the bees could be reached. Mr. Cheshire's first-prize hive of 1874 was further improved by several little additions, and it is in our opinion by far the easiest hive to manage. In Class 3, for hives on the storifying principle, Mr. C. W. Smith took first and second, as last year, for the handsome Carr-Stewarton. The Sussex hive again appeared here, but we were unable to discover its right to claim as a storifying hive. Class 4, hives on the collateral principle, had but three competitors. Mr. Hooker took first, Mr. Pettitt second. There was no special merit in this class, and the Committee would do well to consider the propriety of abolishing it next year.

Class 5, for the most economical (best and cheapest) complete hive on the moveable-comb principle for cottagers' use. The first went to Mr. Abbott for a hive somewhat improved on his exhibit of last year, but spoiled by the same arrangement of frame, guides, and hinges as in Class 2. The second prize was given to Mr. J. S. Wood of Nyborg, Denmark. This exhibit, called the "allotment hive," was a marvel of workmanship, for 10s., but to this must be added its freight from Denmark, which on the point of cheapness prevented it obtaining the first prize to which it was otherwise most certainly entitled. The capacity of this hive is too small for our climate; it is only sufficient to contain eight frames, 10 by 8 inches, but the wonderful pains that had been taken to secure the bees from the inclemency of a high latitude was worthy of all praise. The sides, bottom, and top of the hive were formed of straw 1½ inch thick, well cornered with wood; behind was a shuttered window, and the whole hive covered externally with wood, a good roof surmounted all. In this hive it appeared to us that necessary warmth and ventilation is perfect, and if it could only be supplied in England at anything like the marked price, with some modifications to suit English taste, it would become the hive of the day. A more substantial, better made, low-priced hive was never seen. The same exhibitor sent a three-storeyed hive made after Berplesch. It was made in the same substantial manner as the last described, and it was, indeed, even more weather-proof, being 8½ inches thick of straw.

A two-storey hive received from Baron Ambrosy of Hungary also showed some good economical workmanship, but the arrangement of the frames—i.e., removable only by drawing-out behind, seemed to our English taste most inconvenient. The frames are arranged broadside to the front, so that to take out the eighth frame all the others must be first removed. The Baron Ambrosy is one of the largest bee-keepers in Europe, having two thousand stocks in these hives. One would think gentlemen with such extensive practice would soon discover the best hive.

In Class 6, for the best and cheapest skep for depriving purposes, the first prize was awarded to Messrs. Neighbour & Sons; second to Mrs. Pagden. But for good workmanship nothing could compare in this class with a dome hive, also from Denmark. It was not for competition, as there was no provision for supering. The straw work was as hard as a board, the moulding and sewing of the hive perfect, and at the marked price of 2s. its sale in England would be limitless. The same exhibitor also sent another straw hive called the horizontal hive; it is used on the heaths and moors of Jutland, laying on its side. It was of a most peculiar vase or bottle-shape with a wide

mouth, which the bees close as they like. The collection of hives altogether was most interesting and instructive.

The Association offered a prize of £2 for the best species or variety of honey bees capable of cultivation in England, other than the Ligurian or black bee. Messrs. Neighbour & Sons exhibited a stock said to be Cyprian, and another of Smyrnan bees. The Judges pronounced one lot to be mongrels, the other was undistinguishable from Ligurians, but the prize was allotted to Messrs. Neighbour conditionally on their producing a certificate from Mr. Frederick Smith of the British Museum of their identity; in default the prize to go to Mr. Hunter for Hungarian bees exhibited by him, which according to the French "L'Apiculteur," are famed for their docility and easy appeasement when disturbed.

Perhaps the most interesting things in the miscellaneous department were the honey-extractors. Mr. Cowan exhibited three, all of which were good and much admired. The prize went to No. 160, called the Rapid: this was the only machine which could clear both sides of the comb without removal. At its marked price, £2 10s., it soon found a purchaser, as did, indeed, nearly all the machines exhibited. No. 158, the Cottagers', cost only 25s., and did its work effectually. The Amateurs', at 85s., was the most compact of the whole, not being much larger than an ordinary pail, and with such a machine portability is a great point to consider. One extractor would be enough for a village, and either of Mr. Cowan's exhibits could be easily carried by a boy. An American extractor exhibited had some good points, but was too large for English use. The little power required to set the framework in motion was certainly rather astonishing. In the classes for drone traps, feeders, fumigators, and supers we did not notice any striking novelty; but in that for new inventions calculated in the opinion of the Judges to advance the culture of bees there were some very curious and ingenious things. Foremost amongst them was Mr. Cheshire's arrangement for making embossed wax guides in position. By the aid of this little affair, costing only 2s. 6d., every frame in a hive can be furnished with guide combs, embossed and fixed ready for the bees to work on, in ten minutes. Embossed plates, gauges, and smelters are all superseded by this apparatus, to which a silver medal was awarded; as was also one to Mr. Hooker for an ingenious wooden block for making frames. The bronze medallists in this class were Mr. J. S. Wood and Mr. Carr, the first for an apparatus for laying wax guides, now scarcely required when Mr. Cheshire's is to hand; the other for queen cages slightly modified from those used by Mr. Carr for many years. By what reasoning the Judges arrived at the conclusion of this being a new invention we are at a loss to discover. Mr. J. S. Wood also sent a straw-pressing machine for making straw hives, and a novelty in the shape of wax queen cages, with moulds to make them. This cage is made somewhat like a thimble; the queen is to be put within, and after pricking air holes and the top closed it is put into the hive. The bees gnaw out the queen, which takes them many hours, by which time they have become accustomed to their future sovereign. Mr. Hunter exhibited some simple hive-supports for open driving, by the use of which both hands are at liberty and the upper hive is prevented from slipping; also benzolized wax paste for forming guides and cementing decoy combs like Mr. Wood's smelter. For the former purpose it is superseded, but will be found still useful for the latter. The prize for the best MS. lecture on bee-keeping was awarded to Mr. W. Hunt. We presume the Committee intend to print this for circulation.

Now turning to the honey classes—the prize of the day, £5, for the largest and best harvest of honey in the comb from one stock of bees under any system of management. Grandly among these exhibits stood a magnificent octagon glass super containing 86 lbs. nett of splendid honey exhibited by Mr. George Fox of Kingsbridge, Devon. By its side stood a small straw skep, the hive containing the bees which produced the work, and a written description of their progress. But no prize was awarded; and on inquiring why we heard it said that the Judges did not believe such a hive could contain sufficient bees to fill such a super. Allowing the Judges to be conscientious in their award, we fear here they made a great error. Mr. George Fox is well known as a reputable gentleman, famed for obtaining large supers; and before coming to a decision, which was tantamount to a charge of fraud against one of our oldest and most esteemed contributors, at least it was the duty of the Judges to make some inquiry. If the Committee would have their reputation for fair play stand good it behoves them to call upon the Judges for an explanation of their award if they have not already given one, and see that justice is done to an old and respected bee-keeper. The first prize was awarded to Mr. Cowan for two supers, 80 lbs. nett, which, setting aside Mr. Fox's, fairly deserved the position obtained. Competition was not great, and second, third, and fourth prizes should have been won by something more worthy. Among straw supers of honey there was nothing of transcendent merit, and in ordinary seasons they would have been out of the race. Mr. Cowan and Mr. Rusbridge showed some very good wood supers in Class 11, but the latter had a suspicious white-

to witness the event when it takes place under the normal conditions of the hive. That they do fight and destroy each other was demonstrated by Huber, and his views are corroborated by a practical bee-keeper and accurate observer, Mr. R. Golding, who describes the combat which he witnessed, the clergyman of the parish being also present. The account is given in the shilling bee-book, a valuable little manual, now unfortunately out of print. At the same time it is remarkable that a disabled queen never has the appearance of suffering and distortion which the workers when stung exhibit. May it be that the venom from a queen's sting is of a less acute nature, or does the constitution of a queen resist to some extent the virus of the poison?

That a princess at liberty does destroy other princesses in their cells was also proved by Huber, and I have witnessed the process in an observatory hive from which the old queen had led a swarm. Having no intention of swarming again, the bees permitted the first-hatched princess to open the side of the remaining royal cell. Its destruction occupied about two hours, the bees around offering no opposition, and when the immature young queen was fully exposed the victor retired, leaving the workers to remove the royal nymph.

It is agreed by apiarists that one queen only is allowed to remain in a hive, but that to this rule there are exceptions, apparently when the old queen is superannuated and ceases to lay eggs. My impression has always been that supernumerary queens have been disposed of before the reigning sovereign takes her flight. But this year my observations in regard to this fact have puzzled me, and perhaps some of your apiarian readers may be able to solve the mystery. I will explain the difficulty.

Number 4 hive was determined to swarm with its young queens. Its owner was determined they should stay at home, and after each attempt returned the swarm the same evening, capturing the queens, which were required for other purposes. When this was no longer necessary the next swarm was kept off one night and one day, the result being that two mature queens and two royal nymphs not arrived at maturity were cast out. This was evidently the clearance of supernumeraries. Four days afterwards the young queen took her flight, the same day following, when she returned with the evidence of fecundation. Next day about noon there was some crowding and sensation at the mouth of the hive, and a fresh good queen was brought out just dead. It was equally inexplicable that the healthy young queen of the previous day should have died, or that another queen should have existed after the ejection of the two nymphs; and there was no unusual excitement or distress apparent in the bees. Two days after a fertile queen was presented, and left in a cage forty-eight hours, and then admitted to the hive. As nothing was seen of the queen alive or dead the following day, it was supposed she had been gratefully welcomed, and here unfortunately the observations were interrupted, and the hive removed; but a few days later a dead queen was found on the ground under this hive, leading to the inference that the throne had not been vacant nor her services required. The hive is now in good condition, but I have not had an opportunity of ascertaining if it contains brood.—A.

## OUR LETTER BOX.

**VARIOUS (Dark Brahma).**—No. 1 is the best feather. The yellow tinge in No. 2 is very objectionable. When they sneeze you may give bread and ale, and you may also put some camphor in their water. It is an excellent thing at this time of year. Orvè-Cours will not be confined by a fence 5 feet high. They are excellent layers, especially in winter, and their eggs are large. Their chief merits are they do not sit and they will bear confinement.

**FOWLS DYING (A. B. G.).**—Your fowls die of disease of the liver. Where fowls are in low condition changes of temperature will cause it. The same result will follow feeding on substances that are not sufficiently nutritious. Potatoes frequently cause it; we may say always where they form the principal food. We wish you had stated what their food is. The grass run at the back should do much towards keeping them healthy. Feed them on barley meal or ground oats slaked with water morning and evening. You may give them whole corn or household scraps at mid-day. Give no prepared food of any kind, but confine yourself as closely as possible to a natural diet.

**ERRATA.**—In the article last week on "Cups and Entry Fees" read "deceptive" for "acceptive," and "sop" for "loss," and in report of Stamford Show read "raw" for "rare."

**UTTOXETER SHOW.**—Mr. L. Norris, Trumpington House, Cambridge, had two pens of pullets which were highly commended at the above Show.

**BATH POULTRY SHOW (Gena).**—We agree with you in applauding the Rev. G. F. Hodgson for insisting that "an exhibiting reporter should have 'no admittance' until the conclusion of the judging."

**KEEPING PIGEONS (Anxious).**—You can keep ten pairs in perfect condition in a loft 18 feet 4 inches by 8 feet 6 inches, roof 9 feet high, and even a few more pairs if kept very clean. The best flooring is made of hot tar, over which fine gravel should be sifted. When cold another layer of each. We know nothing impervious to rats.

**MR. WOODBURY (A.).**—We do not know if any of his writings will be republished.

**HIVE DEFECTIVE IN HONEY (Wellington).**—Your hive is like thousands of other hives in having no food for the winter. Give it 14 lbs. of sugar boiled

in twelve pints of water as fast as the bees will take it—say four pints of syrup every night. If the hive is healthy in other respects such treatment will make it a strong good stock for next year. Commence at once to feed it.

**KEEPING COOK AND HEN CAWARIES TOGETHER (A Subscriber).**—In a sufficiently spacious aviary cage you may keep a number of birds of both sexes together all the winter, or at least until the turn of Christmas, when those for breeding purposes may be sorted out and the cock birds kept separate. If you intend breeding with the birds the hens may be kept together until pairing time, when you can match them according to the stock you have and as your fancy directs. Of course you would not think of pairing yellow birds together.

**PRESERVING UNRIPE FIGS (B. & W.).**—Take some half-ripe figs, prick them near the stalks, and blanch them. When half cold throw them into cold water, and then drain them; boil some clarified sugar to *perle*, put in the figs, and give them three or four boils with the pan covered closely; then take them from the fire, skim them well, and, having poured the whole into a pan, set it in a stove for the night. The next day drain off the syrup without removing the fruit, boil it up ten or a dozen times, and then pour it on them when no more than lukewarm. On the ensuing day, having drained off the syrup, boil it to *grande perle*; then add the figs, cover the preserving pan closely, boil the whole up once, skim it well, and put it into pots, &c., for use.

## REMARKS.

22nd.—Dull and dark nearly all day, and rainy after 7 P.M.  
23rd.—Cloudy and dark all day; heavy rain between 6.30 P.M. and 9 P.M.  
24th.—Dull morning, rain before 10 A.M.; fine after part of the day; lightning at night.  
25th.—Thunderstorm heaviest about 1 A.M.; a dull morning, but clearing off, and fine afternoon and night.  
26th.—Rather dull day; rain after 9 P.M.; wind rising, and very strong at midnight.  
27th.—Fine at 8 A.M.; rather dull forenoon; fine in the afternoon, but the wind still very high; and rain at night.  
28th.—Showery all day, very heavy rain at times, but fine and starlit between ten and midnight.

A dark, dull, cloudy week. Showers more or less heavy every day; very little sun, and temperature in all cases, except the minima, 6° below that of the preceding week.—G. J. SYMONS.

## COVENT GARDEN MARKET.—SEPTEMBER 29.

We have very little alteration to quote this week, except that the glut of common fruit will soon be over. Jersey Grapes are now coming very poor, but good samples of Dutch Hamburgs have taken their place, yet have not prevented a slight recovery in value of English hothouse Grapes. Quotations for Kent Cobs and Filberts are slightly lower this week.

From observations taken near London during forty-three years, the average day temperature of the week is 60.6°; and its night temperature 36.0°.

## A FEW CHOICE BRITISH PLANTS.—No. 1.

THE beauty and utility of hardy herbaceous plants being now recognised, it requires only a very slight extension of the same principle to include some of our British plants in the same category, for many of them when viewed impartially and pitted against some tender exotics will be found to put to shame our patronage of the one and neglect of the other. It is true there are some of our prettiest wild plants not the easiest to cultivate, but others, I should expect, may be made to grow in most ordinary situations. I therefore make no apology for calling attention to a few old favourites of mine. Some of them I have been estranged from for nearly half a century, but I expect they still continue to bloom in the same unobtrusive manner they did in the times when Briton, Roman, and Saxon claimed them as theirs. I will point out a few gems in the wild-plant way which deserve more general attention, and the search for which would form a fitting subject for young gardeners when out for a holiday.

*Menyanthes trifoliata* (Marsh Trefoil or Buckbean) is a sub-aquatic plant, with glaucous leaves rather fleshy, the stem robust rather than slender, flowers mostly white, but with a beautiful pink fringe, giving it a most handsome appearance. It is not by any means common in the south of England, but in Scotland our tourist friends will most likely find it plentiful in wet marshy places and on a peaty soil, very often difficult of access on account of the wet nature of the ground, and not unfrequently in a half-floating state. I believe the plant possesses a bitter property common to others of its fellows, and has been used extensively by the poor people, amongst whom it is known as a cure for certain diseases. This plant is easily discovered where it exists; for, notwithstanding its prostrate habit, its pale green leaves look so different from other herbage around it. Its flowers appear in July, and remain in beauty about a month. I have only met with it on peaty marshes, and it may possibly be in company with Sweet Gale and other plants of a like kind.

*Parnassia palustris* (Grass of Parnassus).—This very pretty plant and flower, somewhat resembling a Ranunculus, is, like the last, only found on wet marshy pastures or bogs, but not exactly floating on water, as the last-named is sometimes found, but it is very often hidden by the coarser herbage by which it is surrounded. It is a low compact-growing plant, in habit resembling some of the Primulas with a different class of foliage; the flowers, however, are its main points of beauty, and they are very attractive, being white, neatly fringed, erect, and on stalks that enable them to be conveniently gathered for nosegay purposes. I do not know whether attempts have been made to cultivate it, but it deserves to be where a site suitable for it is obtainable, for, apart from its poetic name, it is very pretty.

*Narthecium ossifragum* (Lancashire (or Bog) Asphodel).—This is a neat little plant with upright spikes of yellow

No. 752.—VOL. XXIX., NEW SERIES.

flowers. It is both pretty and ornamental, and, like the preceding, is found growing on wet marshy ground, but not always confined to soil of a peaty character, for I have met with it on a hungry wet clay where but few things would grow. It is seldom more than 6 inches high, but might possibly attain greater proportions if cultivated; but it is likely to be driven out of cultivation as drainage progresses, unless it fixes its abode on some of those inaccessible wastes where it is safe from invasion.

*Erythraea, centaurium*.—This beautiful annual yields to very few in point of habit and appearance, and it is surprising it is not more grown. It is frequently met with in rather poor pasture land where its fine corymbs of beautifully rose-coloured flowers, equalling the Sweet-william in size, are often met with. As a wild plant it is more easily cultivated than many, especially those requiring some special position not always available. In florists' catalogues it still retains a place.

*Pinguicula grandiflora*.—My acquaintance with this plant is a long one. I recollect finding it in great abundance on a piece of waste clayey land near the margin of a sheet of water in the north of England. Its singularly-formed blooms of a beautiful bright blue with a prominent spur are elevated on neat little footstalks sufficiently above the fleshy foliage to give it an interesting appearance. The foliage somewhat resembles that of the smaller leaves of the ordinary Ice-plant (*Mesembryanthemum crystallinum*), a little more curled at the edges, perhaps, and the plant is of lowly growth. It is only recently that attention has been called to the plant as one to which the term carnivorous has been appended; of its capability that way I can give no opinion. This is a beautiful plant worthy of cultivation.

*Hydrocotyle vulgaris* (Marsh Pennywort).—This is not by any means a florist's plant, but is more plentiful than either of the two last mentioned. It is of low growth, and its rounded leaves supported by stalks in the centre instead of at one edge, as the majority of foliage is secured, is attractive in its way. It is found on marshy peaty places, whereas the *Pinguicula* is more common on bare places on clayey ground, where it grows freely.

*Butomus umbellatus* is a highly ornamental plant, found only in ditches and ponds and other wet places, where its prettily-marked florets, united, as its name implies, into an umbel of considerable size, give it a claim to notice which many exotics really do not deserve. As an ornamental plant it is easily transplanted, and a site suitable for it is easily obtained, as an ordinary ditch even if in the full sun will be found to suit it, provided there be sufficient water. It is reported to be scarce in Scotland, and I do not know that it is plentiful anywhere except in certain localities, but it is well worth cultivating. Those having a piece of ornamental water would find this occupy much less space than the more princely Water Lily, of which more anon; its foliage is also not to be despised, and has sometimes been mistaken for some of the Sedges, which often accompany it in its growth.

*Comarum palustre*.—This is not a water plant, but one

No. 1110.—VOL. LIV., OLD SERIES.

confined to peaty marshes, where its brown-coloured flower-heads rise to the height of a foot or more; and though not possessing the stamp of a flower likely to attract the flower gardener, it is somewhat singular and ornamental.

*Lysimachia nummularia* (Creeping Loosestrife).—This plant is now-a-days worked into higher company than it formerly was expected to keep, not unfrequently being met with in the parterre, and even advanced to the dinner-table. It is a hardy useful plant, and one well adapted for trailing over unsightly objects, or even for training into formal lines, its prostrate habit rendering it available for many purposes. I am not very sure whether the distinctions between this species and *L. nemorum* are sufficiently conspicuous to prevent their being confounded with each other in cultivation; both are, however, British plants, and one if not both are plentiful, usually being met with on shady banks by the sides of ditches. It flourishes well amidst the smoke of towns—in fact it is a town plant of the first order of merit.—J. ROBSON.

### A VISIT TO ARKLETON.—No. 2.

GRAPES are the most popular, and justly so, of all dessert fruits. In quality, appearance, and long season of use they have no rivals. Grape lore is therefore ever interesting to the great community of gardeners and garden lovers. In no branch of gardening are greater efforts made than in perfecting the cultivation of the Vine, and in no branch have greater successes been achieved. There are two distinct modes of Grape-growing, or rather there are two distinct purposes in view—two different goals to be reached. The one is the production of a few immense bunches to win triumphs at public exhibitions; the other is the securing of a large number of medium-sized bunches for everyday table use to win approbation at home. In both these phases of culture it is alike honourable to succeed. But although there are those, and they are certainly the majority, who do not require sensational bunches of Grapes, there are very few, if any, who do not desire to know the conditions under which such Grapes are grown, and the treatment which is given to produce them. Especially is this so when it is considered that he who can produce bunches of unusual size can also, by simply increasing the number of bunches on the Vines, obtain bunches of any lesser size that may be required.

The condition of a Vine to produce extraordinary examples of Grapes must be in the first order of health; its constitution must be sound, and its food and treatment must be in all points correct. A Vine in this state will produce superior Grapes, and large or medium-sized bunches according to the number it is permitted to bear. Hence the grower who can produce large can also produce small bunches, while he who can only produce small bunches cannot perfect larger bunches because his Vines are not in a condition to produce them. In noticing, therefore, the practice of a man who has, as a series, obtained the heaviest Grapes which have probably ever been produced, is to notice a practice which is capable of answering the requirements of all who covet healthy Vines, for, these provided, they can regulate the size of their bunches by the numbers they permit the Vines to carry. That this is sound logic the Arkleton Vines sufficiently attest, for more perfect Grapes of almost every sized bunch, except small, it would be difficult to find than is produced in the vineries of this small but celebrated garden.

Mr. Dickson grows the following varieties:—Black Hamburgh, Mill Hill Hamburgh, Golden Hamburgh, Black and White Frontignan, Black Prince, Muscat of Alexandria, Archerfield Muscat, Tynningham Muscat, Mrs. Pince's Black Muscat, Madresfield Court, Lady Downes', and Syrian, adding also the newer varieties as they are introduced. It is not necessary to particularise the condition of each variety, for all are grown to a high state of excellence, and the Vines are cropped the second year, each carrying seven or eight bunches. There were not to be seen a few sensational bunches only, but examples of splendid table quality, alike fine in berry, colour, and flavour. The Black Hamburgh varied from 3 lbs. to 7 and 8 lbs., and were worth going a journey to see; and the crop of Mrs. Pince's Muscat of the same weights is altogether a remarkable one, but too heavy in all probability for the berries to colour perfectly to the stalk. This is a common and perhaps the only fault of this valuable late Grape.

Wherever Grapes of exceptional excellence have been produced, the first question asked is, How are the borders made? I can tell how the Arkleton Vine borders have been made, and

in doing so I fulfil a promise made to Mr. Blackburn on page 121, No. 724, February 11th, 1875. But it is not the borders alone that possess the virtue of producing these wonderful Grapes. The border must be considered as only one element, and be judged in connection with general management and some natural advantages, the latter being the geological formation of the district and the heavy rainfall. The last might be considered a disadvantage by many cultivators, but as read by the light of the first it must be regarded as of great moment. A depth of 5 feet of rain falling from the clouds and soaking the borders would frighten many dry-district gardeners, and induce them to cry out for shutters; but Mr. Dickson, instead of covering the borders to shoot off the rain (which is really 64 inches), supplements the amount with liquid manure. It is no use anyone shaking his head doubtfully, for the fact is stated, and in that fact lies one secret by which these wonderful Grapes have been produced. But let me not advise any thoughtless attempts at imitation. It is easy to pour on a Vine border 5 or 6 feet of water, but not so easy to put a gravel bed under it for drainage. But now to the borders. A few and plain words are only needed to describe them.

In the first place they rest on several feet of gravel, so that the important condition of perfect drainage is provided by nature. The inside border is 14½ feet wide and 3½ feet deep; the outside border is of the same width and the same depth in front, and 2½ feet deep at the edge next the walk. The Vines are planted inside, and have free access to the outside border. The components of the soil are fibry loam of medium texture taken from an old sheep pasture, and to every twelve cartloads of turf were added two cartloads of old lime rubbish, one cartload of horse droppings, one cartload of charcoal, and 5 cwt. of inch bones. The turf was fresh from the field, mixed well with the other ingredients, and wheeled into the border without lying exposed. That may be taken as a first-rate recipe for a Vine border. It is not necessary to discuss its merits, for the Vines have given their testimony and I shall be silent. I will next briefly notice the inside management.

It must be remembered that Vines so strong as are these require a long summer period to mature their wood. Vines which are less vigorous may be started late and grown cool, and the wood will become solidified; but these require a season both long and warm, and the more so, probably, on account of the many dull days which are a characteristic of Eskdale.

The Vines are started about the end of February. In the first place the border is given a good soaking with warm water from a cistern in the houses. The temperature of the houses is about 45° by night and 50° by day, rising 10° by sun heat; and as soon as the Vines show the first leaf the heat is increased 5° more, and kept gradually rising until the Vines are coming into flower. At that stage the temperature is about 65° by night and 70° by day, rising 10° with sun heat. In the summer Mr. Dickson is not afraid to let the thermometer rise as high as 95° about shutting-up time, say between four and five o'clock, but he would consider such a heat dangerous in the early part of the day. Mr. Hunter's practice of giving air Mr. Dickson quite agrees with—that is, admitting a little air in front instead of at the top or back of houses, which most gardeners are in the habit of doing. He has always found it very difficult to keep up the desired heat at night with top air on, but none whatever with front air. Throughout the whole growing season, unless when it is frosty, or cold cutting winds are blowing, he leaves 1 to 4 inches of air on along the whole front, and whenever the Grapes begin to colour a little air is left on at both front and back by night.

The border is annually dressed with about 3 inches of turfy loam and inch bones, which tend to keep the roots near the surface. A great number of people are of the opinion that when once they have made a good border it requires no more than a little water. That may do for ordinary Grapes; but to grow first-class Grapes Mr. Dickson says we must be liberal with bones and liquid manure.

During the growing season he gives the borders a good watering with liquid manure taken from a tank in the stable yard. This dose is generally given at three different times before the Grapes begin to show colour, and as soon as the Grapes are all out he gives a further good watering, as he thinks it is very unfavourable to the growing of fine bunches to keep the border dry in winter. His opinion is that if good and efficient drainage is provided, and the soil everything that can be desired, that it would be no easy matter to give Vines too much water in the growing season.

In submitting to Mr. Dickson the opinion as to these huge Grapes being produced by chance he replied—"I am aware that a considerable number of people are of the opinion that these monster bunches are produced by chance; but if that be so what is the use of all the heavy manures used to produce big Cabbages, big Leeks, and many other things in the vegetable kingdom? And again in the animal world, why are flock-masters at so much expense for feeding material to produce fine fat sheep, cattle, &c. I have very little faith in the word chance, and none whatever in it having any connection with the growing of large bunches of Grapes." His achievements during his whole career of Grape-growing fully justify him in the expression of that opinion.

The general arrangement of the gardens at Arkleton as to flowers, plants, and vegetables, as well as Grapes, is evidence that skill is devoted to every department.

All who are interested in Grape-growing will join me in thanking Mr. Dickson for his willingness and generosity in permitting his practice to be detailed for the benefit of others. Like Mr. Hunter he has shown true greatness, not only in growing great Grapes, but in telling others how to grow them.

His chief points of practice may be summarised thus—perfect drainage, generous soil, abundant supplies of water, heat, air, cleanliness, and raising his canes from healthy and vigorous stocks.—J. W.

#### NOTES BY THE WAY.

WEYBRIDGE.—The skies were not propitious on the day that, in the fulfilment of an oft-repeated invitation, I went from Cooper's Hill to Weybridge to visit the garden of my friend Dr. Henry Bennet, so well known to all horticulturists by the descriptions of his charming garden at Mentone which have been given in the Journal, and to scientific men by his valuable books. When we left Cooper's Hill it bid promise of finer weather than we had had in the morning; but by the time that we reached "The Ferns" the rain descended in such a steady downpour that it was the pursuit of garden-seeing under difficulties indeed; and yet I saw much that interested me, and heard and saw much that was new to me. What shall I say of "The Ferns" itself? Simply this, that every nook and corner of the house is a study in itself; that everything is in accordance with the most refined taste, and that gems of art in pictures, china, bronze, &c., meet the eye in all directions. Long residence abroad has fostered a taste which gives a foreign aspect to the rooms in their elegance and arrangement, while English comfort has not been forgotten; and I shall not be guilty, I hope, of intruding on the sacredness of the home when I say he has a most willing coadjutor, whose own room is a perfect gem. I suppose it is known to many of the readers of the Journal that sixteen years ago Dr. Bennet, overdone with the demands of a wide and important practice, had to seek in the genial climate of Mentone a relief from the cold and damps of an English winter, and that he may literally be said to go and return with the swallows. As soon as October begins there comes that restlessness for a southern clime which it is said the swallow shows, and when there is prospect of brighter skies he wends his way back to find, as the swallow finds, his nest prepared in England for him; and in both places he carries out his favourite hobby. We have read what he has done with a barren rock at Mentone and have seen the views, which must give but a very faint idea of the beauty of his garden; and while of necessity there can be nothing of the kind at Weybridge, yet he is not one to rest content with mere commonplace gardening, but must be trying to mark out something new.

Dr. Bennet believes it to be possible to utilise Palms for the summer decoration of the garden even in England, and has been trying it with the Date Palm, Chamsrops, &c.; and certainly nothing could well be more vigorous and healthy-looking than those he had plunged out in his garden this season; yet for eight months in the year they are kept in a coach-house, and for the remaining four are plunged out of doors. Through this coach-house he has carried a flue from his greenhouse, and this gives sufficient heat to exclude the frost. He has done this fully believing that we lose a great deal of heat in our ordinary heating apparatus which might well be used to good purpose. This year he purposes putting a glass side to the coach-house, so as to give the plants more light. But here is an instance of how seeming impossibilities may be overcome. Most persons would have said, "But I have no place for Palms,

my houses are full." Not so Dr. Bennet: he seizes on a very unlikely place and bends it to his purpose.

"The Ferns" abuts on the wood or forest which stretches down to Bagshot, and Dr. Bennet has rented a few acres contiguous to his residence, where he has carried out another experiment worthy of noting. All the ground here is covered with Heather; but as we know, Heather grows tall and straggling, and to obviate this he has cut it down with a hook close to the ground, so that a close and beautiful carpet of Heather clothes his land, and next year this will be mown. It will be at once seen how very charming this must be when in flower, the whole ground covered with its brilliant blossoms as closely set together as the blades of grass upon an ordinary sward. Then he had to run out a kitchen, &c. Under ordinary circumstances we know what an ugly adjunct this is to a house with its slate roof. But this would not suit the ideas of taste prevalent at "The Ferns," and so it was made with a flat roof, and over this roof has been raised an iron trellis, on which are trained Roses and other climbing plants of a deciduous nature; so that it will form in summer a charming arbour, while, as the leaves will have fallen in winter, it will not engender any dampness in or about the house.

The plants grown in the houses are principally for decorative purposes, and hence are not grown in collections. In the large house I noticed some Tomatoes, and was told that they had been so grown for years, not for the sake of the fruit, but because the strong smell of the leaves kept the wasps from the house. Have any of our readers any experience of this matter? It would be a simple plan indeed if it were found generally successful. These were a few things I noted in a hasty run through the garden. I hope at some future time, when Jupiter Pluvius is not in the ascendant, to see more of it.

Being at Weybridge I could not omit a call at a garden whose owner has made it famous—Mr. George F. Wilson. Alas! he was not at home, so that I could only see how much he has added to his herbaceous garden, and what gems it must contain in spring and early summer; that he is still as earnest as ever over Lillies, and that his orchard house is, as he has ever made it, productive and satisfactory. The trees were all out of doors. Peaches, Nectarines, &c., had borne their crop, while the Pears and Apples were full of fruit. Surely such an orchard house as this is worth having.—D., Deal.

#### OLLERHEAD'S ROSE HURDLE.

On entering my present situation I found a quantity of isolated Roses worked on Manetti stocks, and planted in small beds along each side of one of the principal walks in the flower garden about 6 feet from the walk; each plant was trained-up two rough stakes about a foot apart, with pieces of tar cord from one stake to the other. The idea occurred to me that something could be done to improve their appearance, which led to the hurdle which I will now describe.

The sides of the hurdle are made of half-inch round iron rods 5 feet high, with claws or feet 1 foot long, and braised together at top and bottom with rods three-eighths of an inch thick and 18 inches long. The space between these uprights is laced with diamond network made of No. 9 bright wire, 5 inches apart, and twisted round the side of the hurdle, and where the wires cross each other they are tied together with lacing wire, so as to make the whole of sufficient strength to resist any pressure in tying strong shoots, &c.

These hurdles are of simple construction, and can be made by any country smith at a small cost, and where stakes have to be purchased, as in our case, they will soon pay for themselves—being durable. They will last for years, and where such things are required they certainly have a far neater appearance than a lot of rough stakes.—JAMES OLLERHEAD, *The Gardens, Wimbledon House.*

#### A TRIP TO LONDON.—No. 2.

##### THE CRYSTAL PALACE GARDENS.

It is with a keen sense of enjoyment that one turns from the unfinished aspect of the grounds of the Palace at Muswell Hill to those of the stately structure at Sydenham, which are constantly increasing in richness, beauty, and interest. The shrubs, Conifers, and other trees are annually assuming more prominence. Mark how charmingly the *Deodars*—flourishing in rude health and vigour—relieve the formality of the south wing by the bright greening which presents itself so agreeably in the symmetrical outlines of the trees and the graceful sweep

of their pendant branches. Ample repose is also afforded by the bold semicircular sweep of lawn along the outer margin, of which a chain of circular beds of Dahlias and Hollyhocks impart an air of finish and dignity that is very grateful. The scene is a perfect one, with every feature in fullest harmony, denoting a master hand equally in its original design and in its present treatment, affording a useful lesson to all who may wish to embellish the surroundings of a lofty building of formal aspect. Nor is this all, for after regarding this particular point as so worthy of admiration for itself alone, we are com-

pelled to recognise its peculiar fitness and unity with those parts of the grounds adjoining it. Let us glance at them.

Proceeding from a central part of the terrace garden towards the rosery, we leave for a time the gayer masses of bright colour of the ordinary bedding type, and pass along winding walks among masses of shrubs where the flourishing groups of Rhododendrons, enlivened just now with a lovely fringe of *Lilium lancifolium rubrum*, are as remarkable for the graceful irregularity of outline as for the pleasing effect of the deep green foliage in contrast with the bright and more chequered

Fig. 68.—CARPET BED AT THE CRYSTAL PALACE.

8. Alternanthera versicolor.
9. Mesembryanthemum cordifolium variegatum.
10. Echeveria secunda glauca.

aspect of the terraces. Beyond these shrub groups on the slopes below the terraces are large beds treated in a singularly bold and successful manner by mixing the showy *Tritoma* with dwarf Dahlias, Phloxes, Hollyhocks, and a dwarf form of the yellow *Helianthus*, all in large bold clumps and sufficiently apart to avoid confusion. Prominent dispersed clumps of Hollyhocks and Dahlias next attract the eye, and then comes the Deodar lawn on the one hand, and dense masses of shrubs of an irregular but pleasing outline on the other; beyond which the rosery, bright with its belting of gay beds and its graceful

surroundings of undulating lawns, curving walks, masses of shrubs, and noble Conifers, meets the eye precisely at the point where its effect can be most fully appreciated.

One pauses here, for the scene is well worthy of contemplation and study, and the question involuntarily arises, Why is this particular part of the garden which one has visited so many times always as fresh and interesting as it was at first? I think the answer is found not simply in the keeping of the grounds or the planting of the beds, to all of which due praise must be given, but in the contour and designing of the grounds

themselves. There is nothing tame here, and therefore it is always enjoyable, simply because the surface is so beautifully undulating. It is just a little bit of Sussex in miniature, toned down, refined, and embellished by the hand of art.

Many of the flower beds were excellent in every respect—soft, rich, and harmonious in colouring, even in outline, and well balanced; but on the whole there was a deficiency of growth and dulness of colouring that detracted considerably from the general effect, causing many of the beds to lack that brilliancy and high finish for which those of last year were so remark-

able. The *Alternantheras* had evidently suffered from the trying effects of the ungenial weather, for they were wanting both in the free growth and high colouring of former seasons. It has been asserted that improper soil is the cause of this, which is a mistake, as it is undoubtedly owing to the baneful effects of an unkindly season, always especially trying to tender plants when growing in such an exposed situation, and even in the sheltered grounds at Battersea a great deficiency of colour is this year perceptible in plants of this class.

Of notable beds a deep purple *Viola* springing-up among

7. *Sedum glaucum*.

white-edged *Pelargoniums* was very fine. The soft scarlet flowers of the *Geraniums* were left on, and rightly so, for nothing could be more charming than the soft yet sprightly effect of such a combination and judicious intermingling of two plants so dissimilar in form and habit of growth. In the chain beds upon the terrace the alternating masses of various shades of pink, white, scarlet, with mottled groups, were very fine, the pink being especially telling—more so than usual, perhaps, from the superabundance of greenish yellow *Pyrethrum* forming a continuous edging to the whole of these beds, and which I venture

to suggest might advantageously be replaced by the soft grey *Gnaphalium lanatum*. I was glad to see my old favourites, Purple King *Verbena* and Lady Plymouth *Geranium*, still in full force and really quite as effective as ever. This clinging to old favourites is a praiseworthy trait on the part of the managers of public gardens. Space should, of course, be given to all meritorious novelties, but it should be done cautiously.

The *Pelargoniums* on either side of the central terrace steps were in fine flower, and I came upon splendid large masses of a bright rosy crimson variety surrounded by a fine belt of

the old pink Christine, followed by another of white-edged Geranium with the flowers kept picked off; then came a rich purple Viola, very fine, with an edging of Golden Pyrethrum—two charming beds, so perfect when I saw them that one could not but regret that the blossom was not as durable as the bright-toned foliage of the carpet beds. Of other good-colour combinations there were lovely chequered masses of *Verbena venosa* and white-edged Geranium, not kept separate but mingling irregularly but very beautifully together; circles of Iresine Lindeni alternating with wide bands of *Gaussia splendens variegata*; rich circles of deep crimson Geranium edged with the grey Gnaphalium, and some grand masses of Amaranth Geranium.

The rosery borders had a pretty design of rich circular masses, around which swept brilliant curved bands which were continued throughout each border. The colouring was bold in character and in exceedingly good taste; it consisted of white, pink, blue, grey, yellow, green, deep crimson, and scarlet.

The carpet bedding comprised many intricate geometrical designs, most of which were fine examples of this justly popular style of bedding, and Mr. Thomson may be congratulated upon the skill in designing and exquisite taste in colouring which they so fully exemplify. An attempt at an imitation of butterflies is, I think, a failure and a step in the wrong direction. So long as carpet bedding partakes of the character of mosaic work it most worthily takes high rank among art works, but when it is diverted into a mere pictorial delineation of insects or other figures it sinks from its high position and becomes a mere toy. Designs of two of the most effective of the beds with the mode of their planting accompany these notes.—EDWARD LUCKHURST.

## ROYAL HORTICULTURAL SOCIETY.

OCTOBER 6TH.

APART from the quaint forms and varied colours of a collection of Fungi, the edible and nutritious qualities possessed by one section and the poisonous properties of the other impart to an exhibition of them material for both study and admiration. One cannot but be struck with their attractive appearance, and regret that the different species—their nature and properties—are so little understood. It is only by bringing collections before the public that knowledge on this generally-unknown branch of vegetation can be disseminated: hence the exhibitions which are occasionally provided. The display on this occasion was only small, Mr. James English, Epping, Essex, being the only exhibitor of note, and who evidenced great industry in collecting and arranging his numerous specimens; he received the whole of the awards. A very fine specimen of *Polyporus sulphureus* was exhibited by Mr. Burnett, gardener to Mrs. Hope, The Deepdene, Dorking; it was of the shape of a half-blown Camellia flower, a foot in diameter, and of a deep sulphur colour. It had been taken from an old Yew tree. Mr. Beech, Castle Ashby, also exhibited some curious specimens.

**FRUIT COMMITTEE.**—Henry Webb, Esq., in the chair. Mr. Beale of Messrs. Carter & Co. sent fruit of an American Grape, supposed to be Catawba, which had been ripened against a wall in the open air. A Raspberry was sent from the Society's Garden at Chiswick called *Surpasse Merveille de Quatre Saisons Rouge*. There was also the white variety of the same, and the fruit was large and handsome. Mr. Richard Smith of Worcester sent fruit of the Worcester Pearmain, a fine handsome Pearmain-shaped Apple of a brilliant scarlet colour. It was awarded a first-class certificate as a valuable market and highly ornamental Apple. Mr. R. Harvey of Bury St. Edmunds sent a seedling dessert Apple called St. Edmund's Pippin, a middle-sized somewhat conical Apple of a pale brown russet colour, with a tinge of brown on the side next the sun. It was rich in flavour, and resembled in this respect the Golden Russet, but is much earlier than any other of this class. It was awarded a first-class certificate. Mr. William Paul sent a seedling Apple called Beauty of Waltham, a large round Apple of the shape of Blenheim Pippin, but quite distinct. If it is a kitchen Apple, and has a white and tender flesh. Mr. J. Murray, Hall Stile Cottage, Hexham, sent a seedling culinary Apple, which was not of sufficient merit to be recommended. Mr. James Clark, gardener to Rev. A. D. Stackpoole, Writtle, Essex, sent fruit of a Pear called Berwick Place Seedling, which is *Grosse Oulabasse*, and also a seedling Apple, which had nothing remarkable in its character. Mr. Mills, market gardener, Turnham Green, sent fruit of Winter Windsor Pear which were unripe. Mr. Peter Grieve sent a seedling Pear, which was unripe, and was referred till the next meeting.

Mr. Francis Dancer of Little Sutton sent fruit of *Fondante d'Angleterre*, a small juicy pyriform fruit, with a thin sweet juice, and which has the property of not decaying at the core.

He also exhibited Madame Treyve and Bourré Hardy, which were of very fine flavour.

Messrs. Carter & Co. sent fruit of their Green Gage Tomato. Messrs. Hurst & Son of Leadenhall Street sent fruit of Hanham's Champion Tomato. Mr. William Heath, gardener to J. Blackwell, Esq., Newton Lodge, Middlewich, sent a seedling Melon of medium size, oval, fine yellow colour, and well netted. It is red-fleshed, and was inferior in flavour through being over-ripe. Mr. Owen Thomas, The Gardens, Drayton Manor, Tamworth, sent a seedling Melon of large size, round, yellow, and slightly netted. The flesh is very white, and it has a large seed cavity. It was of good flavour for the season.

A very large and interesting collection of Apples and Pears, consisting of three hundred varieties correctly named, was exhibited by Mr. William Paul of Waltham Cross, to which a letter of thanks was awarded, and which was of such merit the Committee recommended to the Council the award of a medal. Mr. Francis Dancer of Little Sutton sent a very fine collection of Pears and Apples, which were remarkable for their size and high culture, to which a letter of thanks was awarded. The Committee recommended this collection also for a medal to the recognition of the Council. Mr. Robert Fenn of Woodstock received a letter of thanks for a fine collection of his seedling Potatoes.

**FLORAL COMMITTEE.**—W. B. Kellock, Esq., in the chair. The Council-room presented quite an ornamental appearance on this occasion, Mr. Bull's group of plants being a show in themselves. The *Oretons* were especially in fine condition—viz., *Majesticum*, *Weismanni*, *Imperiale*, *Volutum*, and *Spirale*. These distinct and fine varieties were very effective. The group also consisted of *Cycads*, *Dracenas*, *Palms*, and *Ferns*, with a good plant of *Anthurium crystallinum*. A vote of thanks was awarded for this collection, and a medal was recommended to be given.

Mr. B. S. Williams exhibited an attractive group of table plants, consisting of *Palms*, *Ferns*, *Orchids*, *Dracenas*, &c. *Oncidium tigrinum* had a fine spike of thirty flowers. In bloom also were *Miltonia Morelliana*, a very dark-coloured species; *Cypripedium Harrisonianum*, and *Panoracium speciosum*. *Bertolonia guttata alba punctata* was in exceedingly good condition. A vote of thanks was awarded for the collection.

Mr. Wills, Onslow Crescent, exhibited twelve plants of *Celosias* in a variety of rich colours. The plants were in 8-inch pots, were 8 to 6 feet in height, and deservedly received a cultural commendation.

Mr. Douglas, Loxford Hall, exhibited a bouquet of the single white Macartney Rose, for which a vote of thanks was awarded. It is especially suitable for furnishing vases.

Messrs. James Veitch & Sons had a first-class certificate for *Brahea filamentosa*, a Palm somewhat similar to *Chamærops Fortunei*, but covered with filaments; it is very distinct and ornamental. A cultural commendation was awarded Messrs. Veitch for *Renanthera coccinea*, carrying a fine spike of fifty flowers. The same firm also exhibited *Psecatorea lamellosa*, *Masdevallia Harryana*, *Exacum seylanicum*, *Areca Dicksonii*, and *Artocarpus*; and a like award was made to Mr. Green, Botanical Nursery, Holmesdale Road, Reigate, for *Streptocarpus Greenii*, which has previously received a first-class certificate. Mr. George Smith, Tollington Nursery, Hornsey Road, exhibited plants and cut blooms of his new semi-double *Pelargonium Wonderful*. This plant worthily had a first-class certificate awarded at a previous meeting. It is a sport from *Vesuvius*, is even brighter than the parent, is exceedingly dwarf and floriferous, is an admirable bedder, and as affording cut flowers has no superior, if any equal, amongst scarlet *Pelargoniums*. He also exhibited P. George Smith, a blush variety with a salmon centre.

A first-class certificate was awarded to Mr. Croucher, gardener to J. T. Peacock, Esq., Hammersmith, for *Agave Victoria Regina*. This is a Mexican species which is singularly attractive by its white veins and black terminal spines. This plant received a gold medal at Cologne, and was worthy to have received one at Kensington. Mr. Peacock holds the entire stock save one plant, which he has presented to Her Majesty. A first-class certificate was also awarded to Mr. Noble, Bagshot, for a dwarf variety of *Gynurium argenteum*. It is very distinct with fine compact plumes, and is highly ornamental.

*Thuopsis borealis aurea variegata* was exhibited by Mr. Noble, Sunningdale Nursery, Bagshot, and was requested to be seen again by the Committee. This is a very promising sport, at once decided in its variegation and apparently vigorous in habit.

*Masdevallia Harryana* came from Mr. Stevens, Trentham; *Tropæolum James Russell* from Mr. Russell, gardener to Sir G. Maclean, Pendell Court, Bletchingley.

Mr. C. Turner, Slough, had a first-class certificate awarded for *Pompon Dahlia Dove*, a perfect bloom, creamy white with pink tips, and very charming. A vote of thanks was also awarded Mr. Turner for a box of twelve varieties of bouquet Dahlias.

These blooms were of perfect form and in a great variety of colour. A vote of thanks was also awarded for thirty varieties of large blooms, The Clown, Capt. Webb, Samuel Plimsoll, and Barmid being varieties of great merit. A plant of *Ficus Cooperii* bearing fruit was sent by Mr. Peacock, Hammersmith.

A collection of Fir sprays bearing cones was sent by Rev. G. T. Boscawen, Lamorran, Cornwall. The collection consisted of over twenty species from the common Larch to the Wellingtonia, and from the gigantic cone of the Redwood, 18 inches in length, to the small coral-like berry of the Yew. Some of the specimens were from the Mariposa group, California. The collection was highly interesting and ornamental.

## PLANTS FOR CUT FLOWERS AND SPRAYS.

No. 3.

**RANUNCULUS.**—The Double Persians have the individual flowers  $1\frac{1}{2}$  to 2 inches in diameter, and are as lovely in form as any flower which the florist delights in. They, from their compactness and symmetry, are valuable as cut flowers, but they lack scent, and so do Camellias; neither are all Roses remarkable for rose odour. One *Ranunculus* at least is scented, the Double Persian. Ophir d'Or, yellow, black-spotted; Dollard, white, violet-tipped; Darius, creamy white; Hector, white, tipped rose; Dædalus, crimson; Gloriosa superba, crimson; Fireball, vermilion; Rose surpassante, rose; Ciel Noir, black; and Jaune Supreme, yellow—are all good, and for cutting are as useful in May and early June as the Rose, which unfolds its beauty when the *Ranunculuses* are over. Turban *Ranunculuses* have not the fine imbricated form of the Persian, but have Peony-formed flowers, which are larger and flower earlier. Hercules, white; Merveilleuse, yellow; and Romana, scarlet, will be sufficient of this family.

*Ranunculuses* require deep, rich, moist soil, well pulverised and well aired—exposed to the weather by frequent stirring. The Turban varieties should be planted from October to January, and the Persian from January to March, 2 inches deep, and the roots 4 to 6 inches apart. In severe weather a mulch may be given of litter, partially decayed leaves, or other protective material, removing it before the plants appear. Water during April and May, if the weather be dry, twice a week, and when the flower-buds appear and when in flower every other day or daily, but avoid wetting the foliage. Take up when the foliage is yellow, and store away in dry sand in a cool dry place until planting time. *Ranunculus acronitifolius* flore-pleno has quite charming double white flowers; *R. acris* flore-pleno, double yellow; *R. alexandrinus* with large pure white flowers, are all three well worth a place in a moist position in the herbaceous border, and will produce their flowers in early summer. Though *Ranunculuses* delight in moisture, it is requisite that the soil be well drained.

**ANEMONES.**—We do not recommend these except for the million. No plant is so floriferous, giving large supplies of flowers; in fact, for a quantity of flowers of varied hues a bed of the single *Anemone* from seed sown in July or early in August will give a large supply of flowers the following summer. The doubles may be planted in November to February about 2½ to 3 inches deep, and 4 to 6 inches apart, affording a protection of partially decayed leaves in severe weather. They like sandy loam enriched with leaf soil or vegetable refuse. Though I do not press the claims of *Anemones*, I shall certainly put forward the double Wood *Anemones* (*A. nemorosa* alba plena) and double rose (*A. nemorosa* rosea plena) as of the most valuable, coming-in in spring when flowers are scarce; and having soft stems they keep fresh some time. Then the fiery brightness, orange scarlet, of *A. pavonina* flore-pleno, with its narrow numerous petals, blooms in spring; the more stately *A. japonica*, with its rose flowers; the still finer *A. japonica* alba (Honore Jobert), with the chastest of white flowers, at the end of September onwards, is truly grand as a plant and in a cut state, and ought to have a place in every garden; and even as a pot plant for the conservatory during the early winter months. *A. japonica* and varieties require rich deep loam, and if moist all the better.

**IRIS.**—Growers of the *Iris* have from May to July flowers not put to shame by comparison with *Cattleyas*; the gorgeousness of their colours and the extreme beauty of their form and marking, at once render them the Orchids of the garden. Many are very fragrant, particularly *I. reticulata*, the first to flower, and *I. persica*. The scent of the *Iris* is comparable only to *Violets*.

The *English Iris* (*I. anglica*) in great variety attains a height of about 18 inches, and produces large flowers of various

shades of blue, purple, and lilac; alba grandissima being a fine large white. They flower in July.

*Spanish Iris* (*I. hispanica*) is smaller in all its parts than the *English Iris*, but the colour of the flowers is more dazzling, and they are quaint in form, and the marking is very distinct and varied. The *Spanish Iris* flowers in June. It requires to be planted in autumn about 6 inches apart and 8 inches deep, well-drained light loam being most suitable, though it will grow anywhere except in shade.

*Japan Iris* (*I. Kämpferi*) has what may be termed flat flowers, the petals very broad, giving very nearly a circular form. The foliage consists of rather narrow, sub-erect, lanceolate leaves, spreading in a fan-like order, the flowers being from 5 to 7 inches across. Their colours are blue, purple, rose, salmon, orange, and white, with stripes, blotches, and veins that baffle description. These *Irises* do best in a peaty soil, and if overlying a cool bottom which will afford moisture without stagnation they are at home; in fact, a strong loam growing *Rhododendrons* well will grow this *Iris* perfectly.

*German Iris* (*I. germanica*) commences flowering in May and continues until the bulbous *Irises*—i.e., *Spanish* and *English*, come in, and continues often with those. The varieties are very numerous, and in various colours—blues, purples, yellows, reddish shades, and white, with reticulations, venations, bronze and metallic hues, which give much beauty to the flower, no flower improving so much upon inspection as the *Iris*. The *German Iris* will grow anywhere, forming admirable subjects for the margins of ponds or artificial waters, or in the herbaceous border of strong soil or light. In the open parts of woodland walks spots should be dug and the *German Iris* planted by the thousand. The beauty of a breadth of them is grand for foliage, and gorgeous when in bloom; and what a grand subject is the *I. pseudacorus* in the mass in swampy spots!

*Crimean Iris* (*I. pumila*) flowers in spring or early in summer, and occasionally again in the autumn. It does well in *Rhododendron* beds, and in front of herbaceous borders or the base of rockwork. *I. pallida*, lavender blue, possesses a fine odour; *I. sibirica* has small flowers and narrow drooping foliage; besides those are many other species of *Iris* useful for affording cut flowers. One of the many great claims of *Irises* to favour are their succeeding well in the impure atmosphere of towns, not suffering from dust and smoke.

*Iris persica* does well in pots, potting in September, allowing a space the diameter of the bulbs between them, and half that from the sides of the pots. They should be covered about an inch deep, making the soil firm about them, and give no water until the foliage appears, and then only a little, increasing it with the growth. The pots should be plunged in ashes in a cold pit or frame, admitting air abundantly, but protect from rains, and in severe weather afford mats as protection in addition to the lights. In February, or earlier, remove them to a light airy position in a greenhouse or other structure where they will be gently brought forward. Its flowers are white tinged with pale blue, the interior velvety purple, striped orange and purple spotted, and sweet.

The *Peacock Iris* (*I. pavonia*) has white flowers with three blue blotches, one on each petal. It requires frame or cool-house treatment. Suitable for pot culture may be mentioned *I. chinensis* (Tiger *Iris*), starry red flower, spotted and striped black; *I. iberica*, white, marked with reddish purple; *I. reticulata*, violet, blotched yellow; *I. ruthenica*, blue-purple, netted white; *I. stylosa*, blue, yellow-blotched; *I. susiana*, bluish, tinted brown and netted with dark brown lines; and *I. tuberosa* (Snake's-head *Iris*) with large singular flower, interior petals green, the exterior petals velvety black. They need to be potted in autumn, placed in a frame, and introduced to gentle heat in January or February. In the frame or pit the pots should be plunged in ashes, which will afford generally sufficient moisture, but they are not to be allowed to become dry. **NOTE.**—The *German* and other *Irises* are named under the heading "Bulbs," but they, as everybody knows, are herbaceous plants, and I wish to explain that they are introduced here to make the continuation of their blooming season complete.

**IRIS.**—These, with *Sparaxis* and *Babianias*, are to the spike-flowering *Orchids* what the larger flowers of the *Irises* are to *Cattleyas* and *Lælias*, subjects with flowers of the richest and brightest-spotted, streaked, blotched, flushed, and "tigered" in a manner that cannot fail to please.

All three require similar treatment, which is of two kinds—viz., pot and outdoor. When grown outdoors the bulbs should

be planted in a south border along the front of a greenhouse, and 6 inches deep, the soil being well drained; if the soil is to be prepared, three parts sandy fibrous loam, one part each leaf mould, sandy peat, and silver sand, well incorporated, answers for pots or borders. The bulbs should be 2 or 3 inches apart. A covering of dry leaves, with a little soil over them to keep the leaves stationary, or still better is a straw shutter or a framework of laths thatched, as they throw off the wet as well as afford protection from frost, and are easily withdrawn in mild weather and replaced in cold. Planted in October *Ixia* will bloom in or soon after May, and continue some time; and another batch planted in January in a warm, sheltered, dry spot, raising the soil, if the ground be wet, a foot high, and the bulbs put in 4 inches deep, and mulched with 2 inches of partially decayed leaves, or cooco refuse, and with shutters to throw off heavy rains or snow and to use in severe weather, will lay the foundation for a display in June or July and to August of the finest flowers for cutting that ever graced a border. For pots put five bulbs or six in a 6-inch pot, well drained, the bulbs an inch deep, the soil made firm about them, and after potting place them in a cold frame plunged in ashes, which will afford some moisture, and do not water until the foliage appears, when they may be moved to the shelves of a greenhouse or light airy position, then water carefully at first, increasing the supply with the growth. They will flower nicely, but they will not be as fine as those flowering outside. Varieties are very numerous, and all are good.

*Tritonias* are good alike in borders or grown in pots with cool treatment. The habit of growth is that of the *Sparaxis*, but the bloom differs in being self-coloured. The varieties are becoming rather numerous; parti-coloured flowers are being added, as in Brilliant, orange, dark centre, spotted, and Longiflora roses, blush, white and rose, which add no beauty; but *Eclair*, scarlet, and Prince Alfred, white, are good additions; still the best of the family are *T. crocata*, orange, and *T. aurea*, orange yellow. The former blooms earlier, and grown in pots blooms in June or earlier, according to the temperature, and *T. aurea* comes in at the middle of July if brought forward in a greenhouse. Outdoors they flower after those under glass, and give a succession of blooms for a long time, commencing in August and continuing until frost. A dozen bulbs in a 10-inch pot, potted early in October, watering moderately until the growth appears, but keeping moist as they are more or less active alway, increasing the supply of water with the growth, letting it be copious when in free growth, and brought forward in gentle heat, keeping in a cool house until January, then introducing to gentle moist heat, with a light airy position but plenty of moisture. *T. crocata* will flower during the spring and early summer months, and if kept from frost and brought on in a cold pit or house it will flower later and keep up a succession until those in the open ground come in. Half a dozen bulbs may be grown in a 7-inch pot, and in potting let them be about 1½ inch deep, those in the open ground about 3 inches deep, and afford a mulch of leaf soil in winter over the clumps. The soil named for *Ixia* suits *Tritonias*, or turfy loam will grow them well with the addition of a third part of vegetable soil and a sixth of sand. They like a moist soil, but well drained.—G. ASHBY.

#### NEAR AND AMONG THE ANTEDILUVIANS.

More satisfactory is it to me having things congruous about me. I am in search after things old, so I lodge in a terrace with an Anglo-Saxon name—Holme Lea, the Wooded Meadow; and certain is it that the whole region round about was a forest, that is in the time of the ancient Britons, whose name of the place is still retained. They called it *Lym* from the streamlet on the west bank of which it is, and that they termed "y nant Llym," the Rapid Stream. One of the evidences of its forest surroundings is afforded by the submarine trees found abundantly in the lias between Lym and the mouth of the river Char. It was a woody region even in antediluvian times, for on the table before me as I write is part of the branch of an Oak firmly bedded in a slab of lias, that geological formation from whence the Ichthyosauri and other old-world monsters were dug, which now are in the British Museum. The town is built upon that lias, and in walking along the seashore towards Charmouth you may find many remains of animals and plants that were alive before the Flood. I may be permitted to dwell on one as not irrelevant to your columns, I mean the Coprolites. Their name signifies petrified dung, and certain it is that they are the excrements of the Ichthy-

osauri; they are found within the fossil skeleton of that animal. They are shaped like a kidney Potato. I have one before me; it is nearly 4 inches long, fully 2 inches broad at the widest, tapering to each end, and 1 inch thick. It retains the marks given to it when passing through the animal's intestines, as well as the undigested scales of the fish on which it subsisted.

Coprolites were analysed in the laboratory of the London Manure Company, and proved to contain in 100 lbs., besides a

Fig. 70.—*Lobelia urens*.

small portion of unimportant ingredients, 56 lbs. of phosphate of lime, 14 lbs. of phosphate of iron, and 21 lbs. of carbonate of lime (chalk). These ingredients are what were to be expected, as we know the food the Ichthyosauri and other marine antediluvians fed upon—that food was fish, and in many coprolites, as well as that I have described, are found their scales, and of some so undigested that M. Agassiz at once pronounced one to have been from the body of the *Photidophorus limbatus*. The bones and scales of fish contain the phosphates and carbonate found in coprolites. They are so abundant in places on this seashore that they might be mistaken for scattered Potatoes. This abundance—and it prevails in other

maritime districts—renders coprolites a valuable ingredient for artificial manures, and their manufacturers grind them to a powder and mix them with other fertilisers, for those phosphates are found in cultivated plants.

It is a curious fact that our field and garden crops are being nourished by the excrement of an animal produced before the Deluge. Some estimate may be formed of the abundance of fossil animals in the lias by the fact that Sir Henry de la Beche distinguished more than 180 species; and how numerous was one of the species, the Ammonite, is apparent to any observer. I have a flat mass not 5 inches square and 1 inch thick, that contains at least a hundred small Ammonites. This fossil, known among old geologists as the Cornua Ammonis, has that name preserved corruptly among the poorer classes here, for they call it "Cornomals." Heavy fragments of some that must have been 9 inches in diameter are used to keep doors from closing.

The peculiarities of the plants of the district are no less noteworthy than those of its fossils. One instance for the present must suffice—"The Flower of the Axe," or, as the country people near Axminster call it, "The Flower." Until the present week I never heard of this member of our national Flora, and, therefore, was ignorant that it is found nowhere but on one small spot at Kilminster, near Axminster.

For all my relative information, and the outline portrait accompanying this note, I am indebted to the Rev. Z. J. Edwards's excellent little volume on the Ferns of this vicinity.

The plant is *Lobelia urens* (Stinging Lobelia). It was unknown as a British plant until Hudson published the second edition of his "Flora Anglica" in 1778. He described it as having an erect stem, the lower leaves rounded at the end, scalloped; upper leaves lance-shaped, toothed; flowers violet blue. It is a perennial, flowering in July, August, and early September. On Kilminster Common this Lobelia has a range of about a mile in length, and is no place more than a hundred yards in breadth. In some fields that have been recently cultivated near its usual haunt it has appeared abundantly on the newly turned-up soil. Hudson states that it was first discovered by Mr. Williams Newbery, a noted herbalist, in the vicinity of Axminster.

Since writing the above I have visited Kilminster Common, and, though the last day of September, found many plants of the Lobelia still in flower. Then, as on many other similar occasions, I entered into the feeling that made Linnaeus fall on his knees by the side of the first Furze bush that he saw clothed with its golden flowers. Kilminster Common was entirely mantled with them; the bushes were dwarf, and above them stood forth the blue-flowered stems of the Lobelia. They are 2 feet high, and 9 inches of their summits bear the flowers, alternate, and half an inch apart, so that the drawing copied from Mr. Edwards's volume does not approach to doing the plant justice. The leaves are alternate, the lower being 4 inches long, and 1 inch wide where broadest.

The soil of the Common is stony but wet from numerous springs; yet the water is not stagnant, for the Common is on a hill about 300 feet above the Axe, and facing the south-west, so that when the Lobelia is transplanted to neighbouring gardens it can only be kept in moderate vigour by copious and unremitted waterings.

Kilminster Common is on the road from Axminster to Honiton, and the habitat of the Lobelia is about six and a half miles from the town last named.—G.

### SUMMER FRUITS.

It is true, as stated by Mr. Luckhurst on page 177, that Rivers' Early Prolific Plum stands out prominently in any collection, but I must have Rivers' Early Favourite along with it. These Plums ought to be on every garden wall in the best position they can be placed in, and in the borders too, as pyramids and bushes wherever there is a square yard to be found. I have endeavoured to impress this on many cultivators, especially those in humble circumstances.

Some years ago at an horticultural exhibition held the first week in August, within a few miles of the sea in north Yorkshire, I exhibited a dish each of Rivers' Early Favourite and Early Prolific Plums from the open wall. It was with difficulty that I could persuade those connected with the exhibition that they were grown outside, for they were quite sure they had been grown under glass.

There is another early Plum, *Précoce de Tours*, which in years gone by used often to be met with, and was the earliest

Plum we then had, and I believe the parent of Mr. Rivers' rightly-named Favourite. It is but seldom met with now. I saw many years ago at Old Thornville, the residence of Colonel Thornton, a fine old place twelve or fourteen miles north-west from York, trained on a wing of the mansion a fine old tree of *Précoce de Tours* with one of the heaviest crops of fruit on I ever saw. This was at the latter end of July, and the fruit was ripe and in use. The favourable spring and fine summer no doubt had much to do with the fruit being ripe so early. I have often wondered why fruit trees are not more numerous. I am of opinion that they ought to be as numerous as Thorn bushes. We all know how beautiful our fruit trees are when in bloom in the spring and early summer, and then in autumn we have the pleasure of storing the fruit. In planting it is very important to know which kinds of fruit came the soonest into a bearing and profitable state, and amongst Plums I know none which will pay their expenses more quickly than the sorts I have named.—F.F.

### DIONÆA MUSCIPULA.

I HAVE a plant of *Dionæa muscipula* which is thriving well. It recently threw up a vigorous new leaf, and one morning I found this new leaf tightly closed with the end of an insect's leg just showing between the edges of the leaf. I noticed a brown mark extending from the edge of the leaf nearly to the base of it. I feared that my grand new leaf was going to decay, and I wondered what the food could be that had evidently disagreed with it. A few mornings since the problem was solved.

The leaf opened, and it then appeared that *Dionæa* had captured a wasp, and the brown mark was produced by the sting of the insect. I have not removed the wasp, and he lies in his trap with his sting fixed into the flesh of his captor. It is curious to note the effect of the wasp's revenge on the plant that has made a meal of him.—GEORGE C. STENNING, *Beaulieu Parsonage*.

### SALES OF FRUIT AND VEGETABLES AT COVENT GARDEN.

In Covent Garden Market is transacted the largest fresh fruit and vegetable business of any market in the world, it being the grand centre of distribution not only for London and its suburbs but Great Britain. It receives contributions from the chief fruit-bearing regions of the world, and vegetable products from France, Spain, and Portugal, as well as from more distant quarters. Of fruit, schooners built for the purpose, and faster sailing steamers, are constantly bringing hither supplies from the tropical, intertropical, and temperate zones of America, from the Channel ports of France, the shores of the Mediterranean and Adriatic, and of Northern Asia. Of late years the purveyors of Covent Garden have entered into active competition with the city importers, warehousemen, and dealers in Pudding Lane and its vicinity, fruit and vegetables being now consigned on a large scale directly to them. The Covent Garden dealers have their agents at the leading foreign shipping ports, many of whom dispatch representatives from time to time to the interior fruit-growing districts to report on the crops, and forestall, by advances and agreements to purchase, the native dealers. As crops mature or arrive at port for shipment, a large part of the correspondence between the agents abroad and the Covent Garden dealers is carried on by telegrams, for in these days of competition early advices are essential, the character and amount of prospective supplies exerting an important influence on prices. By large capital intelligently applied, by maintaining an intimate conversance with all the influences calculated to increase or lessen foreign supplies of market garden produce, taking at the same time into account home contributions, these dealers may be said to rule over our supplies, and to some extent to govern prices. It is by the completeness of their organisation in connection not only with producers and intermediate agents, but their connection with the host of retail dealers throughout the country, that the statement holds true that of fruit and vegetables "the best come to London." The tendency year by year has been to vest these large transactions in a few hands, or at least in a few families. To allow of the enormous trade carried on, it has become a necessity to extend the transactions of the market proper to the short streets branching from it north and left, the upper floors and cellars of these affording storage, whilst the ground floor is

given up to samples of stock and sale transactions. But in securing the requisite space for transactions, not only are neighbouring hotels, bars, and coffee-houses resorted to for bargaining, but as in Minning and Mark Lanes, the pavements

and roadways themselves are at times made available, and whole waggonloads of produce are sold by private contract or by auction around.

To be impressed with the absorbing power of Covent Garden

FIG. 71.—THE NEW GLASS-AND-IRON ROOF COVERING, COVENT GARDEN MARKET.

Market one should visit it at early morn to be in time for the arrivals. The noise and stir gradually increase, like a quiet sea being lashed into a storm. From each point of access come all sorts of vehicles, from trucks to farmers' heavy carts and railway contractors' waggons. The members of the vegetable kingdom in season make a huge display on the southern side, and choke up Great Russell and James

Streets, whilst fruit, of which the air is redolent, and the delicate vegetable products of the hothouse and garden, such as Cucumbers and Artichokes, find their way to the northern colonnade and the piazza. Above the crunching of the heavily-laden vans and the tramp of multitudinous feet are heard the voices of porters, market dealers, greengrocers, costers, all on the alert. There is a veritable babel of tongues, of which only

those initiated in market lore can catch the full significance. Covent Garden, like the Cattle Market, Smithfield Meat Market, Billingsgate Fish Market, and Leadenhall Market, has a language of its own. What with the throwing down of huge piles of Cabbages, and crates and boxes, the fillings of baskets, and the rushing of everyone to and fro, unpacking from laden vehicles and repacking in empty ones, the storing in shops and cellars, the depositing of produce on the flagged areas, the incessant endeavours of drivers of vehicles to make headway or to retreat from their positions, the exclamations and oburgations from the hundreds upon hundreds moving in a labyrinth of wheels and hoofs, the cries of the porters in the crowd to clear the way, the excitement of the scene is all but bewildering. Amidst all this uproar one hears in every direction the chink of money. The negotiations are carried on with marvellous rapidity—each seller seems to deal with half a dozen persons at once; yet buyer and seller, such is the throng and the number of counter currents, are like persons bargaining in a heady stream, sometimes in the very act borne out of sight of each other. Thousands of pounds are changing hands; the produce of hundreds of acres being bartered away whilst we gaze. A moment suffices for the bargaining of the retail dealer, and, in fact, with so many competitors he has no choice but to be "sharp and quick." Equally prompt are those who purchase on a wholesale scale, these frequently, through the advantages of capital and the terms they can obtain, supplying the shops of large districts, and this promptly. Thus one man has secured almost the monopoly of the Watercresses by greengrocers in the western central district, being able to obtain them on better terms than they could themselves, not to speak of the saving of time. A large assortment of vegetables and fruit will be selected, purchased, and carried off by a vendor in less than a quarter of an hour.

Up to nine o'clock A.M. the price of produce of the same description is uniform, as fixed by the market dealers. To this price all purchasers must conform; and thus business is facilitated—a consideration to buyers who have little time to spare. The early part of the day is necessarily that most convenient to a large number of greengrocers and other retail dealers. They are supplied before the local trade has well-nigh commenced, and the prices charged by them to customers fluctuates, as a matter of course, with the terms they have been able to secure. It does not follow that this early pricing is satisfactory to the market purveyors or dealers. It is largely influenced by the state of the weather and the general amount of current supplies. If it is desirable to move off a large quantity of any produce, the terms will be lower than otherwise. It would scarcely be interesting to our readers to give particulars of the conclave which result in the determination of the figures to be demanded up to nine o'clock; nor need we explain the interest all dealers have in uniformity. In addition, through custom and common interest, it is a regulation which none dare break. In this period many of the costers as well as shopkeepers are supplied, and purchases are made for the country, to be carried off by early trains.

After nine o'clock all dealers are free to name their own prices, and no one can have visited Covent Garden without noticing the variation in ticketed figures in different localities of fruits of the same quality. Similarly a variation necessarily extends to the sales in larger quantities, whether by private arrangement or by auction. Auction sales are frequently held by various dealers throughout the day. The early sales will, to some extent, have fixed metropolitan prices, and the object of buyers now is to make good bargains. Every regular frequenter is known to the several classes of purchasers, and it is a prime consideration with costers and others to wait the thinning of competitors. The departure of a score of well-to-do greengrocers will accordingly be patiently awaited, in the knowledge that their presence serves to keep prices up, and that they cannot afford to stay. It is a sort of time duel that is being fought, for on neither side can the holding-off be kept up for ever. Many of these auction sales are advertised by slates hung up against a pillar, or in the case of the shipment of foreign fruit being telegraphed a day or two before the stock arrives. There is, in addition, a sort of freemasonry among those interested in market sales, by which information as to goods to be disposed of would seem, without any formal previous notice, to become common property. At these auction sales the produce, as we have stated, is frequently sold in the street waggons as it stands; while of stored fruit

and vegetables opportunity is given for previous inspection, whether above ground or in the subterranean caverns. With foreign and home-boxed fruit all the boxes are sometimes opened as offered for sale; and so, at times, with hampers, &c. It is at these sales the costers mainly buy; as in the city, so here, they constitute an important class of purchasers, being the virtual purveyors of two-fifths of the metropolitan population. It is to be remembered, too, that they buy some of the best fruit and vegetables in the market. These sales give occasion for abundant displays of character, though they are conducted on the whole with a quietness foreign to the city fruit and vegetable sales. Each sale has different stages. There is the reserve price with which it sets out, and which, as soon as demand flags, is sure to be abated. Then again, the best lots are, as a rule, sold first.

The most amusing sales, those which differ in character from all the others, are the latest. What is sold must, as a rule, be sold, whether to clear stock, and so make way for to-morrow's arrivals, or "sorted out" because the "signs of decay" or just "going off" have become apparent. For the first reason we have seen the choicest of Apricots, Plums, and foreign Cherries, Green Gages, and other fruits thus disposed of. A mixed company assembles, including costers, who operate on their own account, and others who hold money for investment that has been clubbed together by half a dozen others, with fruiterers of poor neighbourhoods, whose business will be carried far into the night, and whose customers are not too particular for quality, so that they get cheapness and quantity. The buyers have not a penny to lose; the costers particularly are a shrewd set, capital judges of what suits them, and well capable of "sorting stock." Hemmed-in by heaps of "empties" that serve as tea-tables or smoking couches to a number of wearied market servitors who have borne the burden and heat of the day, we join, not without some hesitation, the aforesaid group, which clusters on the flagged area by one of the closed shop windows. From below the shutters a long narrow panel is removed, showing three grim faces belonging to men whose business is evidently subterranean. The conversation is the genuine staple market talk, a compound of business hints, suggestions, and asseverations as to current prices and qualities of fruit, interspersed with rough social amenities, such as hearty slaps on each others' shoulders and backs, the utterance of broad jokes, followed by loud shouts of laughter at the expense of some butt of their rude wit. Such as it is, there appears to reign a general good-fellowship.

Presently a small thick-set man, brown-coated and grey-trousered, with felt hat of the Vandyke style, mounts a box, memorandum book and pencil in hand. Instantly the three heads at the panel disappear, and from the dark cavernous mouth three boxes of Cherries are pushed out on the pavement.

"Now, what's the bid?" asks the auctioneer, "see, they're prime." One of the boxes is open and a good look is taken.

"Three—four—five—six" (meaning 6s. for a given number of boxes), come like a rattling volley.

Auctioneer gives a hard defiant look, but the fates have ordained that nothing more shall be offered, and the entry of the name of the successful bidder in the auctioneer's memorandum book is followed by successive acceptances of like lots at the same figure.

With small as with large auction sales excitement is apt to grow, chiefly evinced in the sarcasms passed on the condition of the fruit by artful bidders desirous of checking the bids of others, in conflicting claims for the last bid, and sundry personal remarks, which assume, by their pointedness, that the speakers have an intimate acquaintance with each other's domestic and business affairs. To represent the wordy conflicts whilst the auction goes on, we would have to be aided by as many stenographers as, according to Dean Stanley, attended on St. Anthony. In some of these conflicts each unit of the lot seems to become judge and witness when two contestants claim to have bought each the same lot, stretching their necks like cranes towards the auctioneer and vociferating till they are hoarse.

The auctioneer, careful to offend none, looks at all, hears all, and apparently believes none. To carry conviction *pro* or *con*, the buttons of his coat are laid hold of, his arms are pulled by huge brawny hands, whilst ever anon a palm floats over his book to prevent him making an entry before he hears the full case out. In the end the contestants divide the spoils.

"What have we next?" is the cry of the auctioneer, "Oranges."

These pass rapidly to the costermongers, and at an incredibly low figure.

Next come Strawberries.

"I haven't heard you bid," says the auctioneer, accosting a costermonger in a solicitous tone.

"Can't take jam," remarks the peripatetic dealer, making all but the auctioneer laugh.

The lots go at an average of 2s. the dozen baskets (such as in their prime were being sold at the time for 6d. each).

"Let's have the Peaches," says the auctioneer to his men, who, in handing the boxes, rip off the covers. "You can't go wrong. Come, hurry up."

The price reserved is half a crown for three boxes, and some few lots bought at this figure; the rest go cheaper.

"You must give me credit for 6d.," says a coster, aged and decrepid, as he empties the contents of his purse.

"All right," says the auctioneer.

"Ah," responds the coster, with a twinkle in his eyes, "you know me; you'd give me credit for £5."

"Apricots," exclaims the auctioneer. "Bid away, you can't go wrong, surely."

The sale is over; the shades of evening gathering, and Covent Garden, after its fitful day-life, becomes gradually deserted.

It may be well, in conclusion, to trace in a few lines the history of Covent Garden Market. Six hundred and fifty-three years ago (1222) the site constituted part of a garden belonging to the Convent of Westminster, whence the contraction Covent. It devolved to the Crown on the dissolution of the religious houses by Henry VIII., was granted to the Duke of Somerset by Edward VI., and on the attainder of that nobleman again came into possession of the Crown. Edward VI. conveyed it as a mark of royal favour to John Earl of Bedford in 1552, together with a field to the north, termed Seven Acres—whence Long Acre. The property has remained in the possession of the Bedford family ever since. John Earl of Bedford built a mansion in Seven Acres, the square on which the market now stands being the rear garden, and walled. The locality was fashionable, and persons of distinction resided in houses contiguous to the wall. At this time a market was held on the sites now occupied by Southampton and Tavistock Streets, but owing to building improvements the market was transferred to the centre of the garden, which was the signal for the aristocratic inhabitants in the vicinity to seek abodes elsewhere. Vintners, coffee-house keepers, and others, took possession of the wooden houses ranged round, and which at one time had been thought magnificent. The historian Maitland, writing of Covent Garden in 1756, soon after the change, says:—"Things remarkable at present are a magnificent square, wherein (to its great disgrace) is kept a herb and fruit market, two charity schools, one meeting house, a parish workhouse, a cold bath. Hogarth sketches it on an early winter's morning as a medley of tented sheds and hoards, with fires kindled here and there to warm shivering creatures, vegetables collected in heaps lying on the stones or piled in baskets; quarrelsome rakes are issuing from Tom King's coffee-house, a woman is bawling ditties, a quack doctor dispensing his nostrum, and market folks are being served at a stall with rice and milk. To these must be added growers of vegetables and retailers, the whole scene—not forgetting the swords and staves and bob-wig high in the air—making a scene of amusing confusion." The temporary standings were in time made permanent, but years elapsed before these were removed to give place to superior erections.

The market was rebuilt in its present form in 1829-30. It is quadrangular, consisting of a colonnade—north, east, and south—with ranges of shops; a central arcade from east to west, three passages running from north to south, and extensive storage cellars. At the eastern entrance there are capacious conservatories. It is somewhat singular that only in the present year a portion of the wide unsheltered space between the arcade and the southern range of shops has been covered in, an improvement shortly to be extended to the corresponding flagged area to the north. So far from detracting from the architectural appearance, the glass-and-iron roof gives to the market a lightsome appearance previously wanting, and is the more to be admired from its obvious utility. An essential requirement of a good market is abundance of water. This is supplied from an artesian well, which yields 1600 gallons

per hour. The market days are Tuesdays, Thursdays, and Saturdays.—(*National Food and Fuel Reformer*.)

## STRAWBERRY CULTURE.

I THINK "AN OLD SUBSCRIBER" has not read my letter on page 242 with sufficient care and attention, or he would not have found out so many objections to my way of growing Strawberries. Such a formidable host of objections I was not prepared to expect, and as my time is limited I must be excused if I do not notice them all. The first objection, then, that I shall answer is "planting without manure." Well, the fact is my half acre of land where I grow my Strawberry plants is as rich as a compost heap, as least for 12 or 15 inches deep. I have used on this piece of land for the last five or six years from twenty-five to thirty cartloads of manure, and it is consequently in such a high state of cultivation that if I were to omit to use any manure for a twelvemonth my crops would never feel the want of it; and as a proof that my plants have not suffered from "planting without manure," my runners now measure above a foot across them, their fruit buds are formed for next year's crop, and they are so large and forward that some of them are throwing up their flower stalks and bursting into flower. "Planting after Potatoes" is another objection. I again repeat my land is deeply cultivated and manured for Potatoes at the time of planting. They are planted the first week in May, and are ready for sale by the first week in July.

"Taking the runners from each alternate row" is objection No. 5. I do not see what matter it would make if I did, but I do nothing of the sort. I "strike" or root my runners in each alternate row, but I take runners from every plant. My reason for raising my runners in this way is that I find in practice that gathering fruit and striking runners are antagonistic, the runners being trampled to death by the fruit-gathering; and by setting apart every other row for the runners, allowing no person to set foot on this row, I obtain runners at least a month earlier. This I think a very important point, and I am sure my friend makes a great mistake when he objects to so simple and easy a way of securing early runners. Objection No. 6 I pass over, as time will prove what sort of a crop I shall have, but judging by past experience I am led to hope that I shall have a very good one.

But after all the great difficulty with "AN OLD SUBSCRIBER" is to "comprehend" how it is possible to grow 1 lb. of fruit per plant the first season after planting. This is no joke. He is content to wait two years and sometimes three years before tasting any fruit. In reply, I answer it can be done by having the runners rooted early and grown to as large a size as possible during July, August, and September; to plant as soon as the land is ready and the season favourable on land in "good heart," that has been deeply cultivated and well manured. A few of my largest Strawberries this year weighed 2 ozs. each, and I had scores that weighed 1 oz. each. From British Queen, Dr. Hogg, President, and others I could pull thirty Strawberries to weigh 1 lb. I remember reading a short time since of a Strawberry called "Brown's Wonder," that would produce one peck of fruit per plant. Dr. Roden writes to say that "his plants of British Queen this year have produced an average of 8 lbs. per plant, several of the fruit weighing 2 ozs. each." Can "AN OLD SUBSCRIBER" comprehend this?

In conclusion I would offer this advice to all Strawberry growers: Do not rest satisfied until you can produce a good crop of fruit the first season after planting.—W. LOVELL, *Weaverthorpe, York*.

## HOW TO MAKE THE MOST OF A FLOWER-POT.

It has often occurred to me when potting, and seeing the roots of plants winding round the pot in search of food, if their wants might not be specially considered at the time of potting, especially in the case of those plants which of necessity have to be kept in small pots for the decoration of the dinner table, and for fitting into vases, epergnes, &c. To attain the desired result I have for the last two seasons acted as follows:—

After placing the requisite drainage in the pots I procured some fresh cow dung (that from fattening oxen is preferable to that found on pasture fields), and with a broad label besmeared the inside of each pot to the depth of one-third to half an inch, according to the size of the pot. The pots are then put to dry in an airy shed for a few hours, otherwise the wet lining would interfere with the work of potting.

Bulbs of all kinds—Hyacinths, Crocuses, and Tulips especially—are benefited thereby, it bringing out that brilliancy of colour in the latter which is so desirable. Mignonette, Cinerarias, Primulas, Poinsettias, &c., also show, by outstripping their brethren which have not been so treated, that they thoroughly relish it; moreover, it greatly supports all succulent growing plants.

This additional stimulant should as a rule not be given till the final potting, as it is difficult to remove the ball without injury to the roots. In case, however, a plant should have to be repotted, an old table knife should be passed round the pot to cut through any dung still adhering to the pot.

If the pots are required for other plants they must be steeped in water and scrupulously cleaned before using, or the plants may at their next potting come out minus half the roots. I keep, however, all my "cow-dung pots" separate, and only use them for the class of plants above named. I am making experiments with another class of plants, and the result I will state it at some future time.—A. W., *Heighington*.

### GRAPES AT THE EDINBURGH SHOW.

THE correspondents who have favoured me with a reply to my communication in your issue of the 23rd ult. have evidently failed to catch the chief points at issue. My inquiry was, "What constitutes a bunch of Grapes?" I maintain that it is what is produced by one fruit stem from the shoot. If this be so, then the Eskbank Grapes were at least two distinct bunches, for there were two distinct fruit stems with a clear space between them, and in this I am corroborated, I repeat, by half a dozen of the principal Grape-growers and prizetakers at the Show, and I have subsequently received from four of them written testimony to the same effect.

Mr. Curror says that the Judges had ample opportunity to inspect them, but did they do so? or have they said they did? Perhaps like myself they never for one moment doubted the honesty of the bunch, neither would I have doubted it had not my attention been drawn to it by two gentlemen whose faith in its honesty had evidently not been so strong as was mine. From the place which it occupied at the back of the table, and the fact that it was guarded by a policeman, the public had no opportunity of inspecting the shoot on which the Grapes were hanging.

The writer of the second communication signed "D. E.," evidently evades the question, and for reasons best known to himself answers it only by praising the Eskbank Grapes, and depreciating those from Arkleton. Now, I beg to remind him that I wanted the opinion of men who were not interested in either of the bunches. No person can doubt after reading the letter of "D. E." but that this gentleman is a partisan in the Eskbank Grapes, and perhaps one of the party who cheered, but of that more hereafter. "D. E." thinks that for months past I have been living in the belief that all I had to do was just to go to Edinburgh, lay down my bunch and take the prize. Practice in showing has taught me never to be too certain on that score.

I never for once doubted but what the Judges could weigh a bunch of Grapes, but I ask the question, Did the Judges weigh them, or did they leave that for others to do? But before entering on this I must explain matters a little. On the Wednesday morning about six o'clock I called at the Music Hall, but was refused admittance by the Assistant-Secretary (Mr. Young), who declared that none were permitted to enter but the Judges and Committee. I told him that I only wanted to see the Grapes weighed, when he answered me by saying that if I called again about nine o'clock I could see that done; but on returning at 8.40 in company with a friend I was twitted by a gentleman with the following:—"Where have you been? Why weren't you seeing your Grapes weighed? They were weighed half an hour ago?" Now this is a fair question, and perhaps "D. E." will be able to explain. If I was not permitted to be present, and if none but the Judges and Committee were there, where did the dozens of witnesses come from? Who were the parties that cheered (for I am aware they did so)? Who were they that shouted, one 26 lbs. 1 oz., another 26½ lbs., and a third 26 lbs. ½ oz.? Now, to say the least of it, this is not very assuring that there could not possibly be any mistake in the weighing; and if "D. E." is a true example of the dozens of disinterested gentlemen who were looking on and checking the weights, I can understand the reason for the cheering when the Eskbank Grapes were made out to be the heaviest, a course of proceeding which I trust will not esta-

blish a precedent for the guidance of future international shows.

"AN ENGLISH GRAPE-GROWER" says that the Arkleton bunch was much rubbed and appeared to have received injury in transit, which spoiled the appearance of the berries. Now, I beg to state that when I staged my Grapes the berries were neither rubbed nor broken, and no bunch could have carried better; yet when I saw it about nine o'clock next morning I should certainly have had some difficulty in knowing it to be the same had it not been for the board that it was lying on, it was so tarnished that the public had not the pleasure of seeing it to advantage. I will now state a fact which I witnessed myself. When I entered the show-room a gentleman in company with a photographer were working on my bunch to have it photographed, and to give an idea how carelessly it had been tied (after having been weighed), it slipped off the board and fell into the arms of one of the gentlemen—judge from that if it could have a good appearance.

"AN ENGLISH GRAPE-GROWER" expresses his surprise to hear that half a dozen principal Grape-growers and prizetakers at the Show should consider the compact Eskbank bunch to be two bunches, and asks, "What does this mean?" It simply means that in their opinion, and the opinion of many others that I could name if necessary, that it was two bunches of Grapes, because it had two distinct and separate fruit stems springing from the shoot, and I have lodged a protest in the hands of the Secretary against the award being given to the Eskbank Grapes on that score, and I have corroborated my statement that it was not a *bonâ fide* bunch by giving him the names of five gentlemen who are unquestionable authorities. To that protest I have as yet received no answer, but I consider that the Committee are bound in honour and justice to investigate the case, and also that the interests of horticulture justify my bringing the circumstances of the case before the public; for if this award to the Eskbank Grapes has to form a precedent, and henceforth as many fruit stems as can be drawn together and made to form a cluster more or less compact are to be regarded as one bunch of Grapes, it will revolutionise the growing of large or any other bunches of Grapes.

As I said at the outset, the weight is not the point at issue; and though I demur to the proceedings, I should never have thought of challenging the award on that account; and had I been satisfied that I was honestly beaten I would have scorned the action of seeking to detract from the well-earned merits of another, or have envied him his laurels, but under the circumstances I stand by my protest, and maintain that I have grown and exhibited the heaviest *bonâ fide* bunch hitherto produced, and assert my right to any little credit to which the world may deem the producer entitled.—JAMES DICKSON, *Arkleton, Langholm*.

### NOTES AND GLEANINGS.

MR. JAMES ABBIS, J.P., the Vice-President of the successful International Potato Exhibition held at the Alexandra Palace on the 29th ult., has offered a *PICKE OF PLATE* of the value of £10 to be competed for at a similar Exhibition to be held in 1876. Messrs. Gale, R. Fenn, and J. Coutts have also promised special prizes in the event of another Exhibition being held. At the Exhibition held last week we omitted to state that Mr. B. Dean, Ealing, was awarded the first prize for six Round varieties of Potatoes with dishes of similar quality to those which won the £10 silver cup.

— In the western parts of Dorset and the eastern parts Devon we have just seen how abundantly loaded are the APPLE TREES, and are not surprised, therefore, to read in the *Bridport News* that Apples are so plentiful in Devon that they are offered at 1s. a-bag, and cider is considerably less than 7s. 6d. per hogshead.

— We have received from Mr. R. Gilbert, The Gardens, Burghley, a fruit of his new GREEN-FLESHED MELON A. F. Barron. The fruit was of bluntly oval shape, and weighed about 6 lbs. It was regularly ribbed, beautifully netted, and was very handsome in appearance. The fruit was over-ripe, yet it was of excellent quality. It had a thin rind, thick flesh, and remarkably small seed cavity. It was singularly juicy, sweet, and possessed a delicate aroma; it sustains Mr. Gilbert's reputation as a successful raiser of Melons.

— THE Commissioners of Her Majesty's Works and Public Buildings intend to distribute this autumn among the working classes and poor inhabitants of London the SURPLUS BEDDING-OUT PLANTS in Battersea, Hyde, the Regent's, and

Victoria Parks, and in the Kew Royal Gardens, and the pleasure grounds Hampton Court. If the clergy, school committees, and others interested will make application to the Superintendent of the park nearest to their respective parishes, or to the Director of the Royal Gardens, Kew, or to the Superintendent of Hampton Court Gardens in the cases of persons residing in those neighbourhoods, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

THE Cryptogamic Society of Scotland held their first Exhibition at Perth on the 29th ult. The display of FUNGI, FERNS, LICHENS, &c., was extensive and varied. Round the walls of the hall were hung hundreds of sheets of dried Ferns and Mosses. On the centre table, which was beautifully and scientifically arranged, all the specimens were placed according to their species. There were also several drawings illustrating the *Peronospora infestans*, or Potato fungus, magnified five to seven hundred diameters by Mr. Worthington G. Smith, London. On this table there was also a hat made from *Fungus* (*Polyporus fomentarius*) from Transylvania, Eastern Hungary, exhibited by Professor Dickie, Aberdeen. Nearly the whole of the sheets on the walls containing Mosses, Lichens, and Ferns were shown by Mr. Howie, Largo. His collection included forty-eight sheets obtained from Mr. Thomson, Secretary to the Field Naturalist Club, Dunedin, New Zealand, the specimens being collected there; and also 461 sheets of foreign Mosses from Professor Simper, Strasburg. Mr. Croall, Stirling, had a fine collection, comprising two hundred specimens of Mosses, Ferns, anatomical dissections of Seaweeds, and microscopic Fungi. Specimens were also sent from the seats of the nobility and gentry of Scotland. The Exhibition was a great success.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

UNDOUBTEDLY it is a very essential point at this time of the year to fully consider the means to be adopted in the matter of wintering the necessary stock of plants for both bedding and decorative purposes. The resources of a villa residence are often too limited for plants to be preserved according to the owner's wishes, and various plans must of necessity be resorted to. Although there may be no immediate danger by frost, yet as it often comes suddenly it is well to be prepared for it. In the first place I know of no better opportunity than the present for the preparation of the greenhouse by either scrubbing the paint, or if necessary giving one coat of paint before placing plants of any kind in it. After it is dry such plants as *Asaleas* and *Camellias*, as well as most other greenhouse plants, should be brought in; but if a pit of any kind, whether of wood or brick is provided, I would prefer the *Asaleas* and *Camellias* going in that for a month or two, as the atmosphere of a greenhouse is too dry, and the change would be too great perhaps for the benefit of the plants. This would give the room in the greenhouse for the most tender plants, and several others still in growth or bloom, such as *Coleus*, *Balsams*, *Fuchsias*, *Begonias*, *Achimenes*, &c.

*Primulas*, *Cinerarias*, and *Calceolarias* in pots should be placed in frames and protected from wet by the lights, but not without an abundance of air being given in mild weather, and taking care that the plants are kept nearly close to the glass, which keeps them dwarf and causes the foliage to spread out instead of curling-up in a cup-shape as we sometimes see it. It is the extreme wet that we occasionally have at this period of the year that injures such potted plants as mentioned above. This wet, accompanied with cold airy nights, soddens the soil and cools the roots too much, rendering *Camellias* liable to shed their buds, and preventing *Asaleas* ripening their flower buds, which is so essential to a plentiful supply of good-formed flowers.

After having these housed, the next thing is to secure all those plants from the flower garden that are wanted for autumn and winter use, or for the bedding season of next year. These are chiefly the berried *Solanums*, which should be well watered before taking up, and the soil sufficiently removed from the roots to prevent injury, yet to enable them to be potted into as small pots as possible. These must be kept well watered and free from the sun until they have rooted afresh, or the berries may drop. These are useful decorative plants, and should be grown by everyone. The *Chrysanthemums* in the open ground which it is desired to take up should be treated similarly in every respect; and those already established in pots should be well tied-out, and not once neglected in the matter of watering with clear water overhead, and every other time with liquid manure at the roots, and if necessary give them a top-dressing of rich loam and manure. Some thinning of the buds should take place now, especially of the *Pompon* kinds which produce so many; but if any flowers are wanted for a special purpose of

larger than the ordinary size the buds must be thinned more severely, even to one on a twig if necessary.

Again, there are few places where there are not a few *Geraniums* grown for some special purpose, such as covering a dwarf wall, or as single specimens in borders. These must soon be taken-up although they may be still flowering well, unless there is means of protecting them from frost. I have many similar plants doing good service, which I usually leave out till the middle of November, but they are properly protected every night. These are not potted when taken up, but brought as careful as possible to a shed well lighted by a skylight, and as the boiler is there no frost reaches them. The roots are plunged in leaf mould and common garden soil mixed and pressed firm. For a time they are watered overhead till the leaves die-off, after a time these are picked-off and the bare stems allowed to remain dry all the winter, and the roots moderately so till about March. The young foliage appears then, and they are encouraged a little, afterwards worked-out under protection, and encouraged to grow in a similar soil to do duty as before. Other *Geraniums* are treated similarly, that is such as are scarce, but being small they are tied in bundles of from six to a dozen. Variegated sorts being more delicate are kept in frames or the greenhouse in pots each holding a dozen plants. These are cut down in the spring, and when beginning to grow again divided and potted, grown-on, and then hardened-off for the purposes required.

Now that is as little trouble as possible, and is a plan which an amateur may imitate, though, perhaps, not on so large a scale. When the late-flowering plants above spoken-of in the greenhouse are stowed away, the spaces are gradually filled-up with *Primulas* and *Cinerarias*, as well as the bedding plants from frames. Such other plants as *Iris*, *Tropaeolums*, *Heliotropes*, and others similarly tender are generally propagated best in the spring; therefore, they may be at once put thickly in pots and put into the dry places in the greenhouse.—THOMAS RACORD.

#### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

##### HARDY FRUIT GARDEN.

APPLES and Pears are being rapidly gathered and stored. After a long-continued drought, at the time that fruit is nearly ripe, a heavy rainfall more than anything else tends to the speedy ripening-off of these fruits. Cox's Orange Pippins have coloured-up in a most remarkable manner during the few bright days we have had. Suffolk Thorn and Dr. Nellis Pears that showed but little signs of ripeness when the ground was dry, ripened-off directly and began to fall from the trees when the ground was saturated with the rains. We would also draw attention to the fact that many persons gather their fruit from the trees before it is ripe enough to gather. They see fruit lying on the ground at the base of the trees, and if a slight gale should arise more of it may fall off, yet if the fruits are carefully examined many of them will be found to be defective, and some of them may be attacked by the Apple maggot. The true and best test of ripeness is when the fruit parts easily from the trees; if one of the fruits is gently lifted up, and it will part without any effort on the part of the gatherer, then it is ready to be taken from the tree. The fruit ought also to be quite dry when it is gathered.

Peach and Nectarine trees upon the walls now require attention; the leaves will begin to separate themselves from the growths, and should be removed as soon as they part readily. Many persons use a birch broom about half worn, and if this is handled carefully all the leaves can be removed without the buds being knocked off. Those who have but a limited extent of wall surface covered with these trees, and have time to spare, will remove the leaves by hand. Any shoots that are being injured by shreds or ties cutting into the bark should be loosened from the wall and fastened-up more loosely. Walls that are furnished with wires, to which the trees are trained, require more attention at this season than the ordinary wall-trained trees nailed to the walls with shreds; the wires cut the bark if the shoots are tied tightly to them, and canker is sometimes induced. If wires are used they ought to be of iron and painted. Unpainted galvanised iron wire is the worst of all to train the trees to by the roughness caused by the process of coating the surface. If there are any loose branches it is quite necessary to nail them in at once, as the equinoctial gales which may now be expected may break off or otherwise injure loose growths.

We continue to look over the Strawberry quarters, and cut off all the runners as soon as they are formed; we also hand-weed if necessary, as but little good can be done with the hoe at this season. We never dig between the rows at any time. Red spider is very troublesome to us, and seriously retards the growth of the plants during hot weather. The most mischief is done when the runners are badly attacked in the early stages of their growth; but at this time the pest can be the more readily destroyed, the plants can be taken in the hand and the leaves be

immersed in a pail of water in which a sufficient quantity of soft soap has been dissolved; indeed, it has been necessary to dip all the pot plants only quite recently, as the spider could not be kept under by frequent syringing. The difficulty with Strawberry plants is to reach the insects, as they feed upon the under sides of the leaves.

Mr. W. Taylor's remarks last week are very much to the point as regards the influence of soils on cultivation, but soil exercises quite as much influence on the insect pests as it does upon the trees. We could almost venture to say that Mr. Taylor knows nothing of the trouble that we have to keep our plants clean and healthy; and not only does this hold good with Strawberry plants, but Vines, Peaches, Melons, and Cucumbers are under the same control. Gardeners who have had experience only with heavy or clay soil may think too much fuss is made of the difficulty of dealing with insect pests, but this only proves the value of experience gained in such widely different circumstances as that of the different correspondents of this Journal.

#### FRUIT AND FORCING HOUSES.

**Vineries.**—Those who intend to start their Vines about the end of November should have them pruned and the canes divested of all loose bark, thoroughly washing them and afterwards painting with the usual dressing—viz., 2 ozs. of soft soap dissolved in a quart of water, and add to this a little tobacco liquor and thicken to the consistency of paint with flowers of sulphur. A little neat added will tone down the colour. Our attention is next directed to the inside border. The surface soil of this should be removed to the depth of from 8 to 6 inches. If few roots are near the surface the greater depth should be removed. This old soil is to be replaced with some rich dressing. Stable and cow manure in equal proportions answer our purpose best; this is moderately rotted and mixed in about equal proportions of good turfy loam. Many persons might not be able to obtain this, and manure from the hen houses or pigeon lofts could be obtained; this might be used in the proportion of six parts of loam to one of manure. Guano or bones ground to powder are equally well adapted for this purpose. One good Grape-grower always uses cow manure for his Vines, and though he does not grow large or very highly finished bunches we never tasted better-flavoured Grapes. This may not be attributable to the manure, but to the loam, which is medium clay on a clay subsoil, and well adapted for Vine culture.

In the late houses, as is usual when the leaves begin to fall, there is some difficulty in preventing the berries from decaying. The best way is to air the houses freely by day, at the same time warming the heating apparatus; but the heat ought to be turned off in time to allow the pipes to become cool before the house is shut up at night. It is quite as well to shut up close as not, for not only are the nights becoming quite cool, but the atmosphere at the same time is usually laden with moisture. We remove all decaying berries and leaves as soon as they are perceived.

#### MUSHROOM HOUSE.

Some instructions for preparing material for the beds were given a few weeks ago; if the material as directed at that time has been prepared by allowing all the rank steam to be thrown off, the beds may be made up. We make up the earliest beds on the ground if that is not required for forcing Sea-kale and Rhubarb. It is necessary to say that overmoist material may be fatal to the production of a crop, and the same may be said of too much heat. These are two evils that must be guarded against at all hazards. As we have said in former numbers, success or failure rests in the preparation of the materials. The manure can be dried by being spread out in an airy shed, and a large proportion of moisture is thrown off by evaporation. If it is supposed that the bed is too wet at the time of spawning, some very dry decayed manure may be placed around the spawn when it is inserted in the hole. At present no artificial heat is required. The spawn will run better if the house is merely ventilated by day and shut up at night, so that the temperature does not fall much below 55°. Overheating, with a dry atmosphere combined, will be very injurious. If it is necessary, as it will be in a few weeks, to use the heating apparatus, water must be sprinkled about to counteract its drying effects. A word on ventilation. Good Mushroom may be produced if but little attention is paid to the ventilation, but it is much better to see that the house has a renewal of fresh air daily.

#### GREENHOUSE AND CONSERVATORY.

It is now a busy time in this department; all the plants require to be re-arranged. Camellias that have been out of doors since the flower-buds were set have now been removed to the greenhouse. Azaleas and all other New Holland plants will also be placed in positions under glass. At this season it is necessary to lay the plants on their sides to protect them from heavy rains, for as long as there is no danger from frosts the hardier species are better out of doors. We have been repotting stage Paeonies. These beautiful flowers are not quite so popular as the zonal or scarlet-flowered section. They cannot be had at all seasons, and the plants are subject to the attacks of green fly; this may be against them, as people now-a-days like plants that

can be cultivated with the least amount of trouble. If green fly is not allowed to make any progress, but is destroyed by fumigation on its first appearance, the plants will not suffer. The potting material used at this time is lighter—contains more leaf mould and sand, than that used to repot the plants in spring. The mould is shaken from the roots, so that the plants growing in, say, an 8-inch pot, may be potted in one 6 inches in diameter. We drain the pots well and pot moderately firm.

Some young Heaths and other hardwooded plants that were potted in August have filled their pots full of roots, and have again been potted. It is now quite late enough for repotting plants of this nature, but it is better that any young specimens be shifted at once than that they should be checked in their growth for want of pot-room. The Chrysanthemums that were showing colour in the flowers have been removed to the blooming house; the others will be taken in as soon as they are ready.—J. DOUGLAS.

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

JERSEY.—Autumn October 18th, Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

LOUGHBOROUGH.—November 15th and 16th. Mr. W. Pallett, 55, Baxtersgate, Sec.

#### TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, Conifers, &c.*

Hoopes Brother & Thomas, Cherry Hill Nurseries, West Chester, P. A.—*Trade List of Ornamental Trees and Shrubs, Fruit Trees, &c.*

Messrs. William Paul & Sons, Waltham Cross Nurseries, London, N.—*Catalogue of Roses.*

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

ALEXANDRA PALACE SHOW.—We find that Mr. Rawlings of Romford was awarded a special certificate for an excellent collection of named varieties of Dahlias. The blooms were large and in good condition.

ADDRESS (H. E.).—It is not our practice to furnish the names of any correspondents who prefer to write anonymously.

PREPARING QUINCES FOR TABLE (E.).—There are various ways of using them, as in cakes, creams, jelly, marmalade, puddings, tarts, preserves, and as pickles. To detail all these modes would take up too much space, but if you specify your requirements we are willing to aid you.

GLADIOLI NOT FLOWERING (M. H.).—The bulbs ought to have bloomed. Let them remain until the foliage turns yellow then take them up and store in a cool and dry place, planting them again in March. We hope you will have better success next year.

ADMITTING AZALEAS INFESTED WITH MEALY BUG AND CAMELLIAS WITH SCALE TO A NEW GREENHOUSE (E.).—There is little chance of your clearing the plants of these pests in a new any more than in an old house; and though we should not object to the Camellias, we should not admit the Azaleas had we the alternative.

EDGING FOR KITCHEN GARDEN WALKS—MATERIAL FOR WALKS (Idem).—Edging tiles, if stout and hard-burned so as to withstand frost, are best, and for the walk asphalt.

SKATING RINK.—"Goss" asks what is the nature of the flooring of the skating-rink in use at Aston Park and other places?

TWO BEST PEACHES FOR A SOUTH WALL (M. E. P.).—It is difficult to select two of the very best as there are now so many very good kinds, but we give you two selections of two each—Dr. Hogg and Noble, and Crawford's Early and Gossé Mignonne. The last-named is of splendid quality, but the tree is rather subject to mildew.

SELECT PYRTHRUMS (W. W. E.).—No Pins Ultra, Vernalis Defiance, Solitaire, Delicatum, Miss Kirke, Imperatrice Charlotte, Striatum plenum, Carminatum plenum, Boule de Neige, Galathea, Alfred Selter, Roseum Perfectum, Imbricatum plenum, Brilliant, and Princess de Metternich.

MOVING BRIARS STRUCK AND BUDDED THIS YEAR (Brier Stock).—You may move them next November, the stock being as efficiently rooted as they will be in twelvemonths hence, though for sale purposes it is necessary they stand a year to become plants instead of buds as at present.

HEATING A GREENHOUSE (G. M.).—The very best (and cheapest in the end) mode of heating a greenhouse is with a stove boiler fixed inside the house and 2-inch hot-water pipes, and for a greenhouse the size you name you will require four rows of 2-inch piping the length of the house. The boiler may be beneath the stage, or you may have it in a shed at the back of the house. If you have it inside be careful that the smoke-flue, or that carrying off the obnoxious products of combustion, be perfectly tight, none of the vapours escaping by the joints into the house, and take it outside clear of the wood-work.

DEFENCE OF ASPARAGUS PLANTS (T. H.).—The plants being in rows 3 feet apart in beds 4 feet wide, and the beds having 3-foot alleys between, as well as they can be, the plants being 15 inches apart in the rows. Compton's Colonial is a strong grower, but will do excellently at the distance you have given it. We consider Asparagus does best a yard apart and 15 inches

apart in the rows, having no beds or alleys, but planting on a slightly raised ridge.

**PREPARING ALLOTMENT GROUND (H. C. R.).**—We should bring up about 8 inches of the soil deeper than it has been stirred before; or take out a trench 10 inches deep and 3 feet wide at one end, and taking out the loose soil, then loosen the bottom of the trench another spade depth if you can—in fact, digging it, and upon this turn the next trench, and before throwing up the "shovellings" apply the manure and cover it with the shovellings; this being done in November you will have nothing to do but plant in spring, forking over the ground as the work proceeds. We have seen the plan proposed to be pursued by your tenant practised with a very satisfactory result, but not burning the weeds unless they are couch grass or others of a perennial kind, and then it is necessary; but the weeds being of an annual kind, to burn them is to waste the fertilizing property they possess when dug into the soil and there decayed. Phospho guano at the rate of 2 to 3 cwt. per acre would at the time of planting be a suitable dressing for Potatoes.

**FRUIT TREES FOR NORTH-NORTH-EAST WALL (A. Constant Subscriber).**—The wall is about as bad as a full north-aspected one, and would be useless for such Pears as Marie Louise, Williams's Bon Chrétien, and Coe's Golden Drop Plum. Jargonelle Pear would do, and Pond's Seedling, White Magnum Bonum, Washington, and Winesap Plums, with May Duke and Morello Cherries, the latter being very prolific. Information as to the best fruit trees for a north aspect is much wanted, and we should be obliged for particulars of experience.

**BROWN TURKEY FIG FOR SOUTH WALL (F. M. S.).**—This and the Brunswick are the two very best Figs for outdoor culture, the Brunswick not being so free-bearing as the Brown Turkey, but is a better grower. You may safely have the one which has been grown at the back of a vineyard, but we should not advise you to plant it until spring (March), or if you plant this autumn afford a protection over the roots, and cover the branches with two or three thicknesses of mats. Add some well-rotten manure to the soil, loosening it to a depth of 3 feet, the width being the great objection, but we have seen them do remarkably well in a similar position.

**ROSES FOR SOUTH WALL (Idem.).**—We should have *Maréchal Niel* preferably to *Gloire de Dijon*, and *Perle de Lyon* to *Climbing Devonians*, though those you name will answer well. The border should have some strong loam added to it and be liberally manured.

**GRASS TERRACES (J. P. of York).**—We consider your plan much the best, and should not hesitate to adopt it, as with the three terraces you will be able so to arrange matters as to have the outer wall a sunk one, or, better still, dispense with the wall altogether, having neither of the walls shown in your second plan but the wire fence, increasing the width for its position to half that of the width of one of the terraces from the bottom of the slope. The slopes should have a base twice that of the height, and the terraces should not be less in width than double the width of the incline of the slopes. If you object to the wire fence plant a Yew hedge 4 feet from it on the terrace side, or the sunk fence would rid you of any objection to the wall being outside.

**GREENHOUSE GERANIUMS FOR SPRING-FLOWERING (Rodney Stobie).**—Cut them back now, and when they have made shoots an inch long turn them out of the pots and remove most of the old soil, shortening any straggling roots, and repot in the same size pot, shifting into larger in March.

**IRIS (Idem.).**—Pot them now five or six bulbs in a 6-inch pot in a compost of turfy loam two parts, and one part each leaf soil and sandy peat, with a half part of silver sand, making the soil firm about the bulbs, and covering about an inch deep. Stand the pots in a cold frame or pit plunged in ashes, and do not water until the plants appear, and then very moderately, increasing the supply with the growth, and protect in severe weather with mats or other covering; and in February remove to the shelves or other light airy position in a greenhouse, keeping them well supplied with water.

**AZALEAS AFTER FLOWERING (Idem.).**—Place them in a house with a brisk moist heat, repotting if required, and keep therein until the growth is complete. They should be sprinkled with water overhead two or three times a-day, and after the buds are set remove them to a cool airy house, shading from bright sun up to October, or the shade of climbers will be sufficient.

**MADREPSHIELD COURT GRAPE CRACKING (Philip Barker).**—In a badly ventilated atmosphere, and when the watering has been neglected, the border dry in the early stages of the swelling, the berries of this kind are liable to crack; but under good treatment it is one of the very best Grapes. In your case we think the insufficient thinning of the berries the cause of the berries cracking. Gros Colman is a thicker-skinned sort, and is not so susceptible of injury by moisture upon its surface as Madresfield Court.

**FRUIT TREE FOR WEST END OF HOUSE (A. F. Newman).**—The Breda Apricot would no doubt succeed, but the fruit, though abundant, is small, but excellent for preserving. Transparent Grape, the best of all Plums, which ripens early in September, or Coe's Golden Drop ripening at the end, would also be suitable.

**PYRAMID FRUIT TREES FOR GARDEN (A. Would be Amateur).**—The following is a list of kinds that succeed in a cold, high, exposed, and wet district, and would no doubt suit you. Pears: *Doyenné d'Ete*, *Jargonelle*, *Williams's Bon Chrétien*, *Beurré d'Amanlis*, *Louise Bonne de Jersey*, *Comte de Lamy*, *Jersey Gratiot*, *Thompson's*, *Marie Louise*, *Beurré Diel*, and *Bergamotte Esperen*. *Desert Apples*: *Devonshire Quarrenden*, *Kerry Pippin*, *Margaret Downton Pippin*, *Red Astrachan*, *Summer Pearmain*, *Whorle*, *Beespool*, *Cockle Pippin*, *Kiddleston Pippin*, *Nonpareil*, *Sourlet Nonpareil*, *Sturmer Pippin*, and *Sykehouse Basset*. *Kitchen Apples*: *Keswick Codlin*, *Lord Suffield*, *Nonpareil*, *Emperor Alexander*, *Cox's Pomona*, *Mère de Menage*, *Tower of Glamsie*, *Blenheim Pippin*, *Bedfordshire Foundling*, *Dumelow's Seedling*, *Warner's King*, and *Northern Greening*. Plums: *De Montfort*, *Oullins' Golden Gage*, *Green Gage*, *Kirke's Transparent Gage*, *Coe's Golden Drop*. *Kitchen Plums*: *Early Rivers*, *Victoria*, *Orleans*, *White Magnum Bonum*, and *Pond's Seedling*. Probably we have mistaken your requirements, and you do not wish for pyramids, but trained trees for the wooden rails and walls. Those named will answer for either purpose, and we may just hint that the wooden rails would, having a west aspect, suit the kitchen Plums, *desert Apples*, also Pears; the south aspect the *desert Plums*; and the stone wall, that having an east aspect, the Pears marked with an asterisk, and you may add to those so distinguished *Général Tottleben*, *Van Mons Léon Lesclerc*, *Beurré Becheller*, *Winter Nells*, and *Josephine de Malines*. Most of the Apples we should grow as pyramids along the sides of the walks.

**OUTDOOR VINES (F. J.).**—The shoots 18 inches apart should have been allowed to make six leaves and then been stopped, the laterals stopped at one leaf. This is what we presume you have done, and these shoots should be

cut back to within two eyes of their base. The leading shoot need not be stopped until it reach the top of the wall, and then take out its points, and cut this back no more than to remove any unripened part, training it in in the serpentine form its full length. The laterals to be cut-in close to the cane.

**NIGHT SOIL (Idem.).**—You may apply it fresh, placing it rather thinly around each Rose, a spadeful being quite sufficient for each plant, disposed in a circle a foot from the stem, and covering about 2 inches deep with soil.

**PERENNIALS FOR BEDDING (A. M. G.).**—We know of none attaining the same height and flowering at the same time as *Geraniums*. Any of our correspondents having experience of any good hardy perennials for bedding purposes would oblige us by furnishing the information.

**TREATMENT OF SOUVENIR DE LA MALMAISON AND LA BELLE CARNATIONS (Idem.).**—They are climbing kinds, and require to have the shoots trained around columns or half-balloon trellis, to be grown in a greenhouse from the end of September to June, and then outdoors, potting in June, if for winter flowering, after cutting out any long bare shoots. A compost of turfy loam, with a fourth old cow dung and a like proportion of old mortar rubbish, with good drainage, will grow them well. If to flower in winter a temperature of 45° to 50° from fire heat is necessary. Outdoors they should have an open situation, but sheltered from winds and be duly watered.

**TULIPS AND CROCUS FOR POT CULTURE (Drake).**—*Tulips*—Single varieties: *Belle Alliance*, *Bride of Haarlem*, *Canary Bird*, *Chrysolora*, *Duc Van Thol* in variety (the best for forcing), *Keyzers Kroon*, *Pottelbakker*, red-striped, white, and yellow vars.; *Proserpine*, *Rosa Mundi*, *Thomas Moore*, *Vermilion Brilliant*, and *Yellow Prince*. *Double Tulips*: *Duc Van Thol*, fine forcing; *Imperator rubrorum*, *Murillo*, *Princess Alexandra*, *Tourneol*, and *Tourneol Yellow*. *Crocus*: *Albion*, *Bride of Abydos*, *Garibaldi*, *Golden Yellow*, *La Majesté*, *Mont Blanc*, *Othello*, *Sir John Franklin*, and *Sir Walter Scott*.

**BLUE PIMPERNEL (Idem.).**—The blue *Pimpernel* (*Anagallis cerulea*) is less common than the red (*A. arvensis*), but is not by any means rare.

**DEODAR ORDER PRODUCING CONES (G. C. S.).**—It is not unusual, but they do not usually perfect seeds.

**ROSES FOR EAST WALL (—).**—*Gloire de Dijon*, *Maréchal Niel*, *Bombreuil*, all *Tea-scented*, and *Noisette Céline Forestier*, *Earl of Eldon*, and *Solfaterra*. If you want reds, *Alfred Colomb* and *Charles Lefebvre*, which are *Perpetuels*; or whites, *Boule de Neige* and *Perle des Blancches* of the same class.

**STOPPING DECAY IN ELM TREE (E.).**—Clean out the hole thoroughly, removing from it any accumulation of decayed substance, and run into the hole, after filling it with broken bricks, omitting the small particles, Roman cement brought to the consistency of thick whitewash with water, and allow it to dry, then add more cement in a mortar condition, and bring up level with the bark of the tree. This will exclude wet and prevent further decay; but we have still the thickness of the bark wanting, and that fill with a pigment formed of equal parts of clay, cow dung, and cooco-nut fibre, bringing it over the sides of the live bark, and make the surface smooth as in grafting. This removed every three months, and seem to occasionally that it do not crack and fall off, will encourage the bark to grow in that direction, and not unlikely you may cover the hole with live bark. Anyhow, if you only exclude the wet and air from acting on the decayed part your tree will live for many years.

**MANETTI STOCK FOR ROSES—"MAIDEN" (Idem.).**—*Manetti* stock is a free-growing kind of Rose known by that name, and largely employed instead of the *Brier* as a stock for grafting and budding Roses on. "*Maiden*" is a tree a year old or a year's growth from the bud or graft, and which has not been cut-back or "headed."

**EVERGREEN SCREEN (Idem.).**—The American *Arbor Vitæ* is very suitable, and moves quite safely when of large size. You may obtain plants of nearly the height you require, and taken up with good balls and carefully planted would grow well. *Cupressus Lawsoniana* is a superior plant, but *Thujeopsis borealis* is handier and equally fine. *Corsican Pine*, which is, however, not a good transplant, grows quickly, and planted two or three lines deep is an effective screen. The quickest-growing screen (but it is not evergreen) is *Lombardy Poplar*.

**POTATOES IN THE NORTH OF ENGLAND (G. S.).**—Potatoes are now selling at 4d. per stone of 14 lbs. in the markets of Ulverston, North Lancashire; Whitehaven, Cumberland; and Kendal, Westmoreland. The sorts most used there are, we believe, *Sherries* and *Fukes*. So far they have been a fine well-grown crop; but as many are still in the ground in these counties it is quite possible that the heavy rains of the latter end of September may operate prejudicially on the later kinds. During the past month the markets at the places named have been largely supplied, and the prices have been as low as 4d. per stone. 4s. per cwt. may be taken as the medium prices for good tubers.

**PEACHES AS ESPALIERS (S. B. Hants).**—Early York Peach and Lord Napier Nectarine are equally worth a trial in your garden as espalliers.

**MANAGEMENT OF LAWN (B. E. L.).**—You may mow your lawn regularly until November, and then roll it weekly until March, when it will be necessary to resume cutting.

**POSTAL (G. S. Richmond).**—The *Journal of Horticulture* can be delivered to you by post direct from the office by mid-day on the day of publication.

**FRUITS FOR NAMING (T. G.).**—They must be packed in a box or basket, be sent by rail or carrier, carriage paid, and not more than six varieties.

**NAMES OF FRUITS (Dr. Mackenzie).**—Black Alicante. (S.)—*Bergamotte Esperen*. (*Hogg & Wood*).—*Urbaniste*. (W. M. B.).—All the Apples are correctly named except *Cox's Orange Pippin*, and the sort you have under that name is not it, nor can we distinguish it. (E. S. H.).—1, *Braddick's Nonpareil*; 2, *Summer Pearmain*; 3, *Adams's Pearmain*; 4, *Brooks's*; 5, *Golden Noble*; 6, *Calebasse Grosse*. (X. X.).—1, *Maréchal de Cour*; 2, *Beurré Becheller*; 4, *French Codlin*; 5, *Fair Maid of Taunton*. (*Dr. Wallace*).—1, *Norfolk Stone Pippin*; 2, *Golden Reinet*; 3, *Sturmer Pippin*; 4, *Beurré Diel*; 5, *Not known*; 6, *Lemon Pippin*. (J. Connell).—1, *White Doyenné*; 2, *Amandine de Rouen*; 3, *St. Ghislain*; 4, *Cellini*. (S. H.).—We cannot name Plums with certainty without a portion of the young wood. It does not seem to be of any great merit. (*Seybor*).—1, *Beurré d'Amanlis*; 2, *Swan's Egg*. (W. Johnson).—Pears: 3, *Urbaniste*; 3, *Autumn Bergamotte*; 4, *Bishop's Thumb*. Apples: 1, *Gravenstein*; 2, *Winter Greening*; 3, *Cellini*. (J. J. Lorey).—1, *Maréchal de Cour*; 2, *Beurré d'Amanlis*; 4, *Williams's Bon Chrétien*; 6, *Comte de Flandres*; 11, *Beurré d'Amanlis*; 12, *Souvenir du Congrès*; 13, *Forelle*; 14, *Beurre de Capismon*; 15, *Louise Bonne*; 20, *Gloire Morceau*; 25, *King of Pippins*; 28, *Manks Codlin*; 29, *Sturmer Pippin*;

80 and 81 Ribston, Pippin; 83, Margil; 88, Nonpareil. (Jno. Gage).—Hawthornden.

NAMES OF PLANTS (J. Bale).—*Magnolia grandiflora*. (M. H. M.).—*Habranthus* sp. (W. Clarke).—1, *Laetia dilatata* var.; 2, *Polystichum angulare*; 3, *Pellaea hastata*; 4, *Polypodium vulgare*; 5, *Adiantum hispidulum*; 6, *Pteris cretica variegata*. (A. B.).—1, *Adiantum cuneatum*; 2, *A. concinnum*. (G. Mullin).—*Polystichum angulare* var. (S. Kerlake).—Your specimens are too bad to name. The supposed *Myosotamus* is apparently the Tomato.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LES BASSES-COURS DE L'ANGLETERRE.

#### CHAPTER 4.—MICHELDEVER.

THE Dorking breed is of great antiquity, for some have even supposed that it was introduced by the Romans. Aristotle certainly tells us of a five-toed breed of fowls that existed in Greece, and Pliny and others mention that a breed was to be found in Italy possessing the requisite number of toes of our Dorking friends, but whether these birds were the Dorkings of our day we can never know. We may rest assured, however, even supposing they were, that nothing in the times of either Aristotle, Pliny, or Columella existed similar to the Dorking establishment which we had the honour of seeing last week at Micheldever.

We have had opportunities of noticing the crack Dorkings of each year at the various shows for many seasons, and we have had the privilege of seeing many of them afterwards in their own homes, but until we saw Mr. Burnell's we never had seen an establishment containing all the recognised breeds of Dorkings and nothing else. Dorkings of every colour and in every stage of growth there were, and a more perfect sight of its kind we never looked at. Many fanciers who have fine yards of Hamburgs, or Brahmas, or Cochins, as the case may be, so often spoil the actual spectacle by raising less valuable specimens with the best birds, or by the introduction of cross-bred matrons in the various yards for incubating purposes, which to a great extent detract from the beauty of a perfect group. Here, however, there was nothing of this kind, for there was not a bird on the premises that was not a Dorking; and the pens only contained the picked chickens of the season, for Mr. Burnell kills right and left at a very early age, and only leaves the choicer birds to mature in his large grass runs; consequently here the groups were very beautiful to look at. One pen, containing Silver-Gray Dorkings looking bright and fresh from the moult, was one of the most pleasing poultry sights we have seen for a long time.

We will begin at the beginning and go more minutely over this Dorking establishment. We must first say that the soil is chalky, and consequently well drained, which we think must help materially to Mr. Burnell's great success, for on soil which is inclined to be damp we have always heard Dorkings will not thrive. When we first enter the gates we find a large warm corner surrounded by a sunny bank and good shade. This is the chicken nursery. Here in March and April may be found all the coops with the baby broods, which as they are old enough are drafted-off to other runs, and by May or June this spot is cleared again, and nothing more cooped here, or any birds allowed access to it until another spring. Through the intervening months the grass grows and the whole place becomes fresh and free from the taint of its last visitors. This we believe to be another great point, for places where chickens continually live in all through the year cannot be as healthy and fresh as they should be for newly-hatched chickens.

Passing from this place we come into the stable-yard. Here we are met by a pair of capital fox terriers of the best blood procurable, the dog's head especially being very beautifully marked, and "nailers" they seemed at vermin. One of them had just distinguished herself by slaying a stoat which had been found in a run of Dorking pullets. She deserved a silver collar on the spot, for we can imagine nothing more formidable to a poultry fancier than a stoat careering about in his yards. In the stable-yard we found a large room, which was the poultry-room. It was decorated with trophies of bygone shows and birds, in the shape of cups and prize-cards and the sickle feathers that had moulted from winning heroes. Round this room on two sides were large wooden pens with wire fronts, where the birds are penned to judge of their merits before despatching them to the arena of the poultry shows. There were here, too, large galvanised corn-bins, and all descriptions of what the Messrs. Crook call "poultry appliances." We were greatly struck with the great cleanliness and order of everything.

Going on from this room a handful of peas and a whistle called the Pigeons together, and a neat little lot they were. We saw White Fantails, really excellent in tail; and Black and Red Magpies of more than average merit; but the gems of the lot were the Dragoons, not a large lot, only half a dozen as yet, for this is Mr. Burnell's last fancy. A young Blue and a Silver with capital bars we think will, when older, be found near the front somewhere; and then from here we came to the home of

the Dorkings, and we feel we must try and explain a little what Mr. Burnell had to work upon here, and what he has done with his materials.

To begin with, it was a 2½-acre field sloping to the south, the subsoil of which was chalk, with only a thin covering of mould. Round this field there was a thorn hedge, and this is where the Dorking establishment of the present time was made when Mr. Burnell first came to Micheldever. We shall go more minutely into this yard than we have done or shall do with regard to others which we may write of, because we think this must have been the sort of place so many have, and which they are anxious to turn into a poultry establishment, but do not quite know how to set to work. We think Mr. Burnell's mode of proceeding was admirable, and the whole thing done, we should say, at a fairly moderate outlay. To begin with, he gradually allowed the hedges to grow high, which keeps cold winds off and helps to keep intruders out. Then high and strong wire-netting was fastened all round to the hedges to keep out the foxes, which are very plentiful in the neighbourhood. Next a fence was put up right through the middle of the field dividing it into two runs of about one acre and a quarter in each. This fence was made of close wooden rattles, and much resembles the hurdles so frequently used in Wiltshire and Hampshire for penning the sheep. It requires to be renewed once in three or four years, but makes a most admirable and economical fence. Then along the top of the field Mr. Burnell had fixed a strong fence of this same work, only of double thickness, and a narrow strip right across had been taken off the field close to this double-rattled fence. The whole strip is about half an acre, and runs right along the top of the field. This was again subdivided by double-rattled fences into ten or twelve enclosures, and then the actual division of the field was done, and the yards of this large Dorking establishment were made. They comprised in fact two large grass runs of a little more than an acre in each, and ten or twelve smaller grass runs in a row, the whole of this line only containing about half an acre. A moveable wooden house was placed in each pen, strong doors put to each division, and the whole thing was done, and we never want to see a better or more useful set of yards. There were large elm trees dotted about in many of the runs, which afford good shade. One yard had a trio of gnarled-trunked old beech trees, whose foliage was just changing, red and golden leaves being discernible in places. These trees made this pen look beautiful. There were two other old elm trees also that we must tell of, for they contained feathered friends. They stand close together and are quite hollow from old age. At the foot of one of them inside the trunk a White Dorking pullet was sitting, and just over her head on a large knot of the tree was a Wood Pigeon's nest with either eggs or young birds; while in the next tree not a yard off lived a family of Owls, also in the old trunk, and though we could not see them, we saw the remains of various banquets at the foot of their castle inside the walls. It struck us as being quite a happy-family homestead here.

But we must return to the Dorkings. In the first of the large runs we found a dozen or so of splendid Coloured pullets. There was not one badly-coloured bird among them, and any two would have made a good matching pair, so even in colour was every one. In the next run we found cockerels, great-bodied birds with good toes and straight combs, promising to make when matured perfect monsters. Then we saw a run full of white pullets, and a nice lot they were, but more backward than the Coloured, still quite a striking group. Then we saw some Silver-Gray cockerels, among them the bird which was so well to the front at Birmingham and Bath, but he had a brother or two in with him which will soon equal him. Then some Cuckoo cockerels, one of them a splendid colour, with a tail far above the average of Cuckoos. Then we came to White cockerels; we fancied one or two were rather creamy, but this very likely can be attributed to the sap in the feathers, which will be in time outgrown. After them we saw a pen containing all the crack-coloured hens, and a noble-looking lot they were; some quite moulted-out, others in the process of moulting. We were shown the heroines of many an exhibition, and we should say they will be such again if all goes well. From this run we visited others, all containing beautiful young birds, three or four cockerels in a pen, till we came to the last, where we saw the Silver-Gray hens, and a more beautiful trio of hens we never saw together. They were in the most brilliant condition, and we could not help exclaiming, "Oh! why are they not at Nottingham, instead of being at home idle?"

When we had thoroughly "done" all this department we walked to a large farmyard which Mr. Burnell rents, and here are found Dorkings of all colours, sizes, and ages enjoying the fullest freedom; there they will live till they are selected-out and drafted into the establishment which we have just described. We must not forget to mention a beautiful pen of Rouen Ducks which we saw here, the drake especially a good bird. We shall soon hope to see the fox terriers and the Dragoons and the Rouens coming to the front in the prize-lists, following the example of their Dorking companions.

We had a little time to spare still, so we went to two or three cottages where Mr. Burnell has some cockerels out at walk, and we were astonished to find how interested these cottagers were in the well-doing and successes of the birds they had been from time to time looking after. As we walked back to the house Mr. Burnell told us that he personally superintended everything, and only had a boy to do the rough work, and to this fact we attribute a great deal of the Micheldever success; for as we have written in former articles, it is simply useless for anyone to buy valuable birds and then leave them to the care of the gardener or some inexperienced person, for prize poultry require great care and regular management, and unless they have it will only bring disappointment to the owner. We are certain that the personal supervision these birds have had from the first days of the yard being started has to a very great extent been at the bottom of Mr. Burnell's extraordinary success in the world of "the exhibition Dorking."—W.

### THE CRYSTAL PALACE SHOW.

I SHOULD be glad to see a point in the schedule of the Crystal Palace Show cleared up by someone possessing official authority before the last day for entries, as otherwise some of the Dorking exhibitors may be placed in a difficulty. In the list of cups and pieces of plate it is stated that No. 2 silver cup, presented by Mr. H. Beldon, will be given for the best pen of Dorkings, cock and hen, in Classes 1 and 2—that is, in the classes for coloured cocks and hens; but the silver cup No. 5 is offered for the best pen of Silver-Gray Dorkings, cock or hen, in Classes 7 and 8. Now is cup No. 2 offered to the exhibitor who shows the best cock and the best hen, or will the prize go as before to the best bird in the two classes? As the schedule stands no exhibitor has a chance of securing cup No. 2 unless he shows a cock as well as a hen; but I question whether this was Mr. Beldon's intention, and I hope the matter will be made clear.

I am sorry to observe that the Committee still adhere almost entirely to the single-bird system, which no doubt is the best system in some cases, but not where the number of exhibits is so large as at the Palace. A friend, who some years back was among the most successful breeders of the day, went over the Dorking pullet class with me last year, and we both came to the conclusion that to pick out the best birds in such a crowd of competitors was simply impossible. If this be true of the Dorking pullets, how much more is it of the Brahmas? Pairs to me are much more interesting as well as a better test of skill in breeding, and they certainly are far more easy to judge.

I regret, moreover, that the managers have not made some concession so as to allow two or more birds in the same class to be sent in one basket. Some restriction of the compartment system is no doubt advisable. The one I have indicated seems all that is required, and I trust they may yet be induced to relax the rule which requires every pen to be represented by a different basket. Last but not least, the Show would in my opinion be far more acceptable to exhibitors if the birds were sent on Monday instead of Saturday.—A CRYSTAL PALACE WINNER.

### NOTTINGHAM SHOW OF POULTRY, &c.

THE second annual Show of the Nottingham Society closed on the 6th inst. (yesterday). The Exhibition was well managed, the Committee being in attendance, and a good staff of servants kept the birds clean, and they were fed during the whole time with Spratt's poultry food made into paste, as well as dry corn, which we consider good management. Turner's pens were used, and the structure in which they were placed was of wood, erected in conjunction with that of the dog show in the market place. The schedule was a good one, and the entries came up in good force, especially the poultry. In these some portion were single cocks and pairs of hens. This being the case in Game, which we consider a mistake, as these are usually quarrelsome, and no bird shows singly in better form than Game.

Black Red Game cocks were a fair lot, though some were a little coarse. Hens or pullets a large class; the first good, but second a mistake, pen 16 being next best. Brown Reds, first a cock, grand but not in full feather; second a cockerel rather coarse, and rest poor. Pullets were good and well placed. Any other colour cocks, first and second Duckwings, very good; third a Pile, quite equal. Pullets, first and third Duckwings, and second a grand racy pair of Piles. Dorkings, cocks, first a grand dark bird, and the rest but moderate; but hens a good lot. Cochins, Buff, cocks were good, the first a grand old bird, and the rest chickens. Hens also good, the winners young Partridge cocks; the first a grand showy bird; the other winners also young. In the following class adult birds won first and second, and pullets third, but these were in a very dark corner. In the next classes White won all the prizes, although there was one nice pair of Blacks we should have liked to see placed. Brahma cocks, first a grand old bird, and second and third young; the third nicely spotted on the breast, a point not to be

objected to. Hens, a nice pair of hens were first, these were beautifully laced; second hens not so forward, but large. Brahmas, Light, cocks not good, but the hens a splendid class. Hamburgs were shown cock and hen, and as a section they were very good. Gold Pencils were first and a good class, but in a dark part of the Show and difficult to see, otherwise the awards might have been different; first and second were good pens, but third poor as compared with those highly commended in the next pen, 189, the cock having a black tail. Silver-pencils not numerous, but the winners very good. Blacks were a grand class and well placed, as also the Gold-spangles, of which there were only five pens. In the Silver-spangles there were some splendid birds, especially the first-prize cock, which, though a little heavy on the back, had a perfect tail; but we considered the third-prize pen superior to the second, the cock being poor in head. Spanish cocks rather coarse in face; the third finest in that respect. Hens were very good and in fine order. Houdan cocks were a bad lot, but the hens very good in all respects. In the next class Orpingtons were to the front, and both were very good classes. In Polish the first were a grand pen of Silvers, second and third Golden. Pen 204, unnoticed, contained a grand hen. In the Variety class the winners were first and third Malays, and second Sultans. Bantams were also in pairs. In Black Reds the first cockerel was a nice stylish bird, but the pullet was perfectly white on ears; second cockerel also stylish but heavy in tail, but pullet good; third had no good points. Pen 309 (Bell) by far the best, the cock a model in all respects as a Game cock. Brown Reds not good. Any other Game, first a grand pair of Piles, and second Duckwings also good, third Piles. In any other varieties most were noticed, the first going to the best pen of Silver Sebrights we have seen of late; second and third Blacks. The whole of Messrs. Long's and Leno's birds, with some others, too late. The Selling classes were large, and contained many good pairs.

Both Aylesbury and Rouen Ducks were very good; but the East Indian rather large. In the Variety class a nice pair of Chilian were first, Brasilians second.

Pigeons were not equal in number to poultry, no doubt on account of the majority of the classes being in pairs in place of single birds. Carriers were, however, shown singly, as also young Dragoons and Pouters. Carrier cocks were but a moderate lot when Mr. Yardley's heavy Black was left out. Hens were better, and here also Mr. Yardley was unfortunate, having the heavy hen also left out on account of a little deformity. The first was, however, a nice bird, but a little flat-wattled; second and third moderate young birds. Any other colour cocks, first a very young but promising bird, very strong and well built; and second a Blue, bad in colour; rest poor. Young Carriers mustered well, and were fair classes. In cocks first was a neat Black. In hens first was Dun, very young; second Black; and the best and third a Silver. In one class of Carriers and three of Pouters there was no competition. Pouter hens any other colour had five entries; first a White, which on the first day looked best, but on the second day would no doubt have changed places with the second, which was showing different; third a smart Red of grand colour. Almonds no entries; but in any other were some good Agates. Dragoons formed some of the best classes both as regards numbers and quality, and were generally well placed. Fantails were pretty good; but of foreign Owls there was no competition; and Trumpeters all of the old style and nice birds. English Owls were a very good class; first Silvers and well placed; second rather poor Silvers; third Blues, which we should have placed second, this pen containing the best cock in the Show. Jacobins were not good; but the Turbits very nice clean-thighed birds; the first Reds, second Blues, and third Silvers. Antwerps, Short-faced, were a good class considering they were in pairs, and the winners Red Chequers, though some of the best were too late for competition. In Long-faced Antwerps the first were strong Duns; the second Red Chequers, and the award a mistake, as the hen is more of a Dragon than a Carrier. Pen 573 we should have put second, and 578 third, both highly commended. Any other breed were first Red Swallows, second Blondinettes, and third Blue Swallows. The Selling classes were really good, and there were many cheap pens, which would no doubt find fresh owners.

GAME.—Black-breasted Reds.—Cock or Cockerel.—1. G. Lucas, Mansfield. 2. E. Winwood, Worcester. 3. F. Sales, Gwoly. 4. G. E. Fitzherbert; J. Palmer. 5. J. Calladine. Hens or Pullets.—1. W. Smith, jun., Easthorpe. 2. J. H. Bradwell, Southwell. 3. W. Roe, jun., Newark. 4. G. Wilson. 5. E. Blom. 6. Hon. & Rev. E. Dutton.

#### MONMOUTH POULTRY SHOW.

This Show was held on Wednesday, the 25th ult. The birds were shown in Turner's pens.

Dark Brahms came first on the list. The first was a very 1 and in Antwerps were some crack birds, the winners Short-faced

feathering; second is next; two grand class. In *Dorkings* he cocks were only sites, second Buffs. Oréves was first, as made only two pens; 1 of feather. *Hambro* cockerel with a pond pen. In *Gold-pens* were beauties. The first in *Silver* the moult; second glad all through, the east; third the pullet *Silver-pencilled* only pen, and those out rest, and second and ood lot; the cockerel pond and third pens pen of *Silver-faced* liver third; several nmenations. Any k *Hamburgs* came sbury *Ducks* good. of White Call were good *Light Brahms* ys and *Gees* good, he prise cards on as ything in order for

east. 3, E. Fritchard, W. Morris, Rose. *Light*, h, Worcester. 4, Mrs.

**JUDGE.**—Mr. E. Hutton, Pudsey, Leeds.

### THE JACOBIN.

I HAVE read the articles of Messrs. Huie, Ure, and Harrison Weir with no common interest, and though not quite agreeing with them as to what a Jacobin ought to be now, yet this I am sure of, they have described exactly what a good Jacobin was thirty or thirty-five years ago. Historically, then, they are no doubt correct, but it is of course an open question as to whether the Jacobin of to-day is an improvement upon his predecessor. In some respects I think he is, in others not. I have at this time in my loft birds of the strains, and from the studs of Messrs. Fulton, Vander Meerch, Captain Hill, and Heath. These birds are of various types and sizes, showing how different good birds of the same variety may yet be. There are in my opinion three things which must be borne in mind in regard to improvements in any class of fancy Pigeons: 1st, What the bird was in olden times as shown by the old authorities, particularly Moore; 2nd, Whether the improvement is merely something that is difficult to breed, which I call a mere fancier's beauty; 3rd, Whether it is at the same time a true beauty.

I think the very high out in Jacobins is an instance of the second, but directly contrary to the other. As regards real beauty, I mean artistic beauty as opposed to fancy, there can be no doubt that a Jacobin with a little rim of clear white coming neatly under its chin is a much prettier bird than one with the dark colour right up to its beak. The very high-out birds have, to my eye, a kind of choked appearance, and the head is not bald, only the top of it. I am glad to find that Mr. Fulton does not condemn low-out birds, and candidly owns "on the average we certainly think the best birds we have seen in hood, main, and chain have been clean-thighed and low-out."

This brings me to the "clean thighs," which I must say upon great consideration and watching the birds closely I now prefer to the dark thighs. It is said that this marking gives a Baldhead-Tumbler look. My answer is, Not the marking, but the present stumpy shape of so many of the birds—so opposite to the old birds which were not Tumbler-shaped, but "slim in girth," as says Mr. Ure, and "long and tapering from the shoulders," as says Mr. Huie. The clean thighs were liked by Brent; and the pair from the pencil, I believe, of Mr. Harrison Weir in Delamere's "Pigeons," published by Routledge, are so marked, while I own the majority of illustrations are the opposite. Still the thighs are so seldom wholly dark that the clean thigh marking lingers in the blood of the bird, and I think the birds are more artistically beautiful with the coral legs and feet coming out of the white thigh; their clean thigh and bald head seem to go properly together in Pigeons. The old books are quite silent on

this point. Regarding the rose, Mr. Esquilant as long ago as 1867 spoke of that property in print, as well as the mane.

Although not an exhibitor, I should be pleased to give towards a prize for Mottled Jacobins as near the old type as possible, the judge to be Mr. Harrison Weir. Perhaps others would join me; and if we lived to see the Crystal Palace Show of 1876 the plan might be carried out then and there. I am sure with Mr. Huie the Light Mottles were the best birds of the old style, and whether looked at with the eye of a fancier or an artist they were as to shape and colour extremely pretty—soft, silky-feathered, slender long-flighted birds, with a very clear pearl eye and small head, and not a trace of the Tumbler form in them, which the solid-coloured birds so frequently have now-a-days. The mane and rose I accept as great improvements upon the old type of bird.—WILTSHIRE RECTOR.

### NORWICH AND NORFOLK BIRD SHOW.

It may appear strange to many—it does somewhat to me—that within the short space of a month two all-England bird shows should be held in the same city, the one I am now chronicling bearing the title of the "Norwich and Norfolk Ornithological Society," and the other to take place the latter end of the present month, known for the past two years in the bird world as the "East Anglian Association." But there is no accounting for these freaks, if such they may be termed. It has been truly said, "All the world's a stage." So it is, and as the performers become more numerous so will each section require a stage to perform upon. As with a hive of bees which becomes overstocked, a new colony is established under a new queen. The same with bird fanciers when there are too many to serve under one head or government. But these matters of rivalry are not confined to the city of Norwich. Whether it be wise for the holding of the two exhibitions is not for me to determine. It appears that the new Society has found an able leader in the person of Mr. Hovell, who with a practical Committee of Management brought to bear an Exhibition of no mean kind; and that it is intended to be carried out annually there appears no reason to doubt, judging from the wording of the title-page on the excellently-compiled catalogue, which announces it as "the first great annual Exhibition."

I was glad to learn that the patronage—that of royalty, too, by-the-by—and support received was sufficient to encourage the able Honorary Secretary in issuing a schedule sufficiently attractive for fanciers to enter largely if so disposed. But no doubt the very early period of the Show taking place was, to a considerable extent, a drawback so far as entries were concerned, for only five exhibitors effected entries in each of the two Clear Norwich classes. This to me was more surprising when I come to reckon-up the number of exhibitors residing in the city. Out of seventy exhibitors in the entire Show no less a number than thirty-six were residents of Norwich, the remainder being distributed over other parts of England. No doubt the entries would have been more numerous had the Show been deferred to a later period of the season. Notwithstanding, the promoters were deserving of all the encouragement received, and more than that.

The plants and shrubs used for decorating the hall were kindly supplied by Messrs. Ewing, of the Royal Nurseries, Eaton, and Messrs. Daniel Bros. of the Royal Seed Establishment, Norwich. I have witnessed bird-show rooms furnished more extensively with birds and cages than the late Norwich Exhibition, where many hundreds of them have been massed in lines together upon the stages without any relief to the eyes. To this the bird-breeding and bird-exhibiting sons of the cause have little objection, for when they visit a bird show it is very little else that interests them beyond their particular pets. Still I like to see some taste exercised in setting out a show-room, and in that particular respect everything that could be wished for was witnessed at the Victoria Hall on the 24th, 25th, and 27th ult., the week of the holding of the great musical festival or festivals, for the birds were a festival of themselves. Betwixt the two last days of the Show Sunday intervened—a day of rest, I trust, for those who had been so previously taxed in their exertions to make the Exhibition worthy of the bird-fancying sons of the city.

The prize list of awards having been printed in the Journal of last week, it would be useless going through the whole of the classes. Suffice it to say, that considering there must have been some demand upon the attention and patience of the two Judges, that if any error occurred it must have been an oversight. Perhaps that will be the best way of summing matters up, although I should have been more satisfied to have found the first-prize a Clear Yellow Norwich instead of a Ticked one. But every one is liable to a mistake, some more than others, and so I thought "Mr. William Evans, of 6, Brazil Street, Lower Broughton, Manchester," when his Golden-spangled Lizard (No. 180) was proved to have been painted about the wings!

Throughout the Norwich, Crested, Cinnamon, Yorkshire, Belgians, Coppies, and Plain-heads, Lizards, Mules, and British

and foreign birds, there were numerous fine specimens exhibited. Amongst the Norwich birds in particular some were very "tall" indeed in colour, most of the principal prizes being claimed by Norwich fanciers, Messrs. Frowart & Willis and Messrs. Mackley. Mr. Adams took four prizes in Norwich, besides a first for a splendid Buff-crested bird. In the Lizard classes Messrs. Bunting and Fairbrass were the chief contestants, the former for choice. Mr. Thackrey was the chief winner in Yorkshire birds, Mr. Shackleton going in strong with Lancashire, Mr. Thackrey won the Treasurer's cup, and Messrs. Mackley the Mayor's cup, besides the tradesmen's cup. The chief exhibitor and winner with Cinnamon birds was Mr. Adams, with his high-coloured specimens, which have no more lost their natural colour than did the Norwich birds at a show some two years back in the north of England, when the public were invited through the medium of posting-bills to "go and see the wonderful Canaries." If they be wonderful in one instance, why not in the other? Belgians—especially Mr. Reid's—were good.

The fight betwixt the Mule exhibitors lay with Mr. Bunting and Messrs. Mackley. The latter proved the victor, although one particular bird (a Buff), and I might say another (a Yellow), were the plums in Mr. Bunting's lot; but the Yellow Mule is now dead, and if I mistake not Messrs. Mackley also sustained the loss of a good Mule bird.

I will conclude by stating that Queen Polly, a talking Parrot belonging to Mr. Barrow of Monkwearmouth, won a silver medal as the best talking bird in the Show.—Quiz.

### A BATCH OF QUESTIONS.

UNDER this heading I think it will be well to answer a number of questions forwarded to me by the Editors. It is exceedingly pleasing to me to see so many readers of the Journal anxious to comprehend the full meaning of all that is written in it. In our anxiety to be brief and occupy little space we sometimes fail to make ourselves understood. For instance, Mr. John Davies does not understand what Mr. Pettigrew means by the following sentence in his letter on Bee Gossip—"The combs containing brood are put into a hive or box, and bees put amongst them to hatch the brood." I do not understand how this can be done. How can these brood combs from different hives be fastened in one hive or box? for fastened they must be, I presume. No, they are not fastened, but simply laid in either on their edges or broadsides, with little bits of sticks or combs to keep them asunder. The combs containing young bees or brood rest on the bottom of the hive or box, and have a lid or board placed over them. The bees speedily adopt the combs, fasten them together, and hatch the brood in due time.

We do not think that the statement which Mr. Davies has found in a number of a popular journal is true—viz., that "the honey extracted from the flowers of dahlias is certain death to bees." We grow dahlias, but never find them hurtful to bees. We hope that Mr. Davies will not be influenced by the statement and cast away his dahlia roots.

"L. J. K." who has resolved to commence keeping bees in a small way, may purchase them at once and have them wintered in her own garden. Hives are generally higher in price and more difficult to find in spring than they are in autumn. Both the Ligurian and the common bees are good workers; it has not been proven which is the better sort. Bees will thrive in a Woodbury or other hive for two or three years, and may be removed from it without resorting to the brimstone slaughter.

"Is there any truth in the popular idea that bees never do well in a place to which they have been brought across the water?" "L. J. K." lives across the Thames from Reading, and she is told her bees must come from Oxon, not from Berks. Is there truth mixed with the fable? There is no truth at all in it. Bees that have been bought do as well as those that have been given; and those that come across the water and those of Berkshire are quite as good and eligible as those of Oxon or anywhere else.

"B. B." seeks explanations of certain passages in the "Handy Book of Bees." 1. On page 183, second edition, it is stated that "when hives are less than 80 lbs. in weight the bees are taken from them by a speedier mode than driving. We shake them out in less than half a minute of time." "B. B." succeeded in shaking the bees from the combs in this way, "but as soon as they found themselves in the empty hive they rose on wing and covered him." Of course the sudden and unexpected shake startles the bees and makes them fly. This often happens; but knowing it, we cover them speedily with a board, and thus prevent them from flying. By placing the hive with the bees on the spot where the old hive stood the bees outside enter it at once. This operation is all the work of a minute. If done in the evening or on a cold day the bees that rise on wing sit down on the operator or other object near, as they do in natural swarming when a cloud comes before the sun. If they commence to alight on me in this or other operations they are shaken off, and I go out of their way for a minute.

2. The picture on page 64 representing "two boards marked for sawing out of a deal board" is meant to teach how little wood is wasted in making bee boards. "B. B." asks if these boards as marked can be cut out with an ordinary saw. I answer that they are easily cut out with a narrow saw, such as carpenters and wheelwrights use for such work. A common saw cannot follow the circle.

3. The picture of the feeding board and trough as seen on page 114 is sufficient to guide any tinsmith to make such boards, troughs, and cisterns. The top of the trough of the feeding board is on a level with the board itself. "B. B." is quite right in supposing that the cistern and smaller feeder are meant to be used at nights.

4. "How is it possible to make straw covers look as neat as those in the picture on page 66?" If "B. B." will give a commission to any handy man about a farm to cover his hives after the pattern of the book he will have this work done to his satisfaction. Or he may do it himself by combing a bunch of clean straw with his fingers, laying it as straight as he can, and tying it very tightly at the narrowest end; then dip it in water, spread it over the hive, hoop it on with an iron or wooden hoop, and clip it neatly. We have seen many quite equal to those of the picture.

Lastly, "B. B." asks, "What should be the gross weight of Pettigrew hives, 14 inches and 16 inches respectively?" I presume he means when they are filled, and measure about 12 inches deep. 45 and 60 lbs.; but if they now weigh 80 lbs. and 86 lbs. respectively they have honey enough in them to keep the bees alive till the end of March next year.

"J. H. E." has reason to suspect that a Pettigrew skep has within the last week become queenless, and wishes to know how he can most simply and satisfactorily ascertain if this is so (without driving preferred). And supposing a queen is reared, is it probable she would be fertilised at this season? It is rather difficult to teach others how to discover the symptoms of a lost queen. If the bees are rearing a young queen there will be no external manifestations of their loss. If there are queens set in royal cells they may be seen by an internal examination, and their existence will indicate with certainty that the old queen is dead or about to be dethroned. If the royal cells are empty and the hive without a queen, the bees may be found now and then running about the hive, both inside and outside, making a great noise, which indicates their grief and loss. Bees bereft of their queens, and without eggs in their hives, are easily thrown into fits or paroxysms of grief or lamentation by disturbing their hives. During these fits their grief is manifested in a very violent manner. If it comes to it at last, "J. H. E." may easily drive or shake the bees from his hive to see if they have a queen. If a young queen were reared now, the probability is very great that she would remain unfertilised and useless.—A. PETTIGREW.

### HONEY SEASON NEAR LINCOLN.

A SWARM of June the 5th, weight of hive 5 lbs. 6 ozs. June 8th, weight of hive and bees 10½ lbs. To July 8th I had given 5 lbs. of sugar, with five pints of water. On the 8th they had clustered outside of the hive, so I cut a hole in the top of the hive, and put a glass super on. Up to the 19th the bees did not take to it, so I replaced it with a bar-frame super made of 1-inch wood, 6 inches square, and 6 inches deep, with four bars, each an inch wide. July 18th weight of hive and bees 21½ lbs. To July 28th I had given 11 lbs. of sugar. The bees began to build in No. 2 bar from the east side. August 3rd, twelve young bees out dead; 8th, a great number of drones out, and honey in super, a few young white drones and bees out dead; 16th, bees began to kill all the drones, and began to fill No. 8 bar; 18th, began to fill No. 1 bar. Up to the 24th I had given 18 lbs. of sugar, weight of hives, &c., 40 lbs., so I took off the super, and No. 2 bar weighed 1½ lb., some of it sealed up. On the 25th I gained a prize at the Bracebridge Show; 26th, replaced the super, gave 1 lb. more sugar. September 6th, weight of hive, &c., 44 lbs.; 7th, took off the super again, No. 2 bar weighed 1 lb. 8 ozs., so I kept it off, as I found the bees were plundering it. September 17th, weight of hive and floor-board 39 lbs.; the weight of hive I allow 5½ lbs., and board 5½ lbs. The bees are numerous and strong, but they are quiet this month. I think the weight of bees and honey, 28 lbs., will be sufficient to carry them through the winter without any more feeding; 18th, I noticed them very busy to-day carrying in pollen, so I judge they are breeding yet.

I have visited a friend four miles from here who had fifteen hives; all the swarms are light. They had only three parts filled the hive with comb. I think they had no more than 3 lbs. of honey in each (they always suffocate them to take the honey), so I offered to drive them, and very pleased they were to have it done, and gave me the bees for my trouble. On the 9th I drove one swarm (at 6 p.m.), and joined it to the next one (a swarm). The next was an old stock, but I could only get part of the bees out, and the next one I succeeded in a little

time, and joined the two together, and carried them home at nine o'clock.

I then took my bar of honey from my super, and placed it in the top of an empty hive, and turned the bees to it. I have fed them from an empty box below, and they have built two large combs each side of the bar, and they are doing well. They have had 5 lbs. of sugar and five pints of water up to to-day, the 18th.

On the 11th I again drove the hive with little trouble. There were over 20 lbs. of honey and some young brood, so I placed it in an empty hive (with string), and drove one more, and joined the two together; and drove one more swarm, and joined the next one to it, and all are doing well. On the 18th I drove one more, and joined it to the next one, and I have two hives out of three for myself. Both are doing well.—J. M.

### OUR LETTER BOX.

**ATLEBURY SNOW (J. C.).**—There is no error; the award is as you state it should be.

**POULTRY FARMING.**—*"Gallinaculturist"* would oblige several correspondents by more details of management.

**WRIGHT OF DORKINGS (Constant Reader).**—You do not give the age of the Dorking cock. It is considered good growth if in an ordinary way a cock puts on 1 lb. per month, but that is not sufficient to win with. A bird eight months old, good enough to win in November, should weigh 9 or 10 lb. If the competition is close and the show really a large one. A 9-lb. cock chicken in really good feather, with a bright upright stiff comb, clean white legs, and well-defined five toes is hard to beat. But at many shows that dub themselves "grand," and inform all England they are at liberty to compete, a Dorking cock of 8 lbs. "walks over." The pullet should weigh from 6½ to 7 lbs. Here again condition goes a great way. A competent judge should always take age into consideration, but it must be remembered there is but one restriction, that the competitors shall be birds of the year, and that, given equal symmetry and condition, the heaviest bird must win. There is no weight agreed upon for Call Ducks. It is unnecessary there should be, because the smaller they are the better. Large size would be detrimental to success, so would be long head or bill, or white plumage, or a white ring round the neck in the Duck.

**TURKEYS UNHEALTHY (H. G.).**—Your Turkeys are suffering from the change of weather. There will be many complaints now both of fowls and Turkeys; as the weather gets colder the nights are longer, the surface of the earth alters, and yields no longer the same amount of natural food. The fowls and Turkeys find the effects of it. It is so with yours. The cure is to change the dietary, and to add somewhat of stimulant till they are accustomed to the change. Give them soft food; it is more nutritious and cheaper than whole corn. Let it be oats and barley in equal quantities, with one quarter of pea-meal all mixed together, slaked with water or milk. If they have a daily meal of stale bread soaked in ale it will do them good. It is only inflicting needless suffering to open the swelling round the eye. It is the result and symptom of disordered health, and will disappear as strength returns. They should be fed three times per day while they are out of condition, and always if they are to do well. They should roost in a dry place.

**BRAHMA FOWL UNHEALTHY (A Fifteen-years Subscriber).**—The bird has been allowed his liberty too soon. Any black discharge must be carefully removed with a sponge. If there is any gaping of the incision, and if it shows ragged edges, they must be removed with very sharp scissors; the lips must then be brought together, and the wound and suture completely covered with stiff grease. This must be continued. The bird should be confined where it can have nothing but that which is given. The food should consist of stiff gruel and ground oats mixed with milk. All food for the present must be liquid. If you have no ground oats give bread crumbs soaked in milk.

**PIGEONS (J. E.).**—The Rock Pigeon has nearly always enjoyed the prefix of "blue" to its name, but we believe genuine Rocks are often found varying from blue to blue-checker, and from red to red-checker, and mealy; these latter are rare. Years ago, when the Rock Pigeon was abundant in Lincolnshire and Yorkshire, many hundreds were sent to Leadenhall, and there were always as many Blue-checkers as Blues. Very few real Blue Rocks are now sent to the London markets; the majority of the Pigeons there sold as Rocks are foreign. The wild Dove-house Pigeon you mention is the Rock of more or less purity of breed. If your Pigeons are imported Antwerp, it is more than likely they have been accustomed to roost out. Many breeders in Belgium make their birds do so. Your disturbing them night after night would make them very shy of the lookers for some time.

**SICK PIGEONS (—).**—Bathe their eyes with alum and water night and morning, wiping them with an old silk handkerchief. Cold and damp are the causes, particularly draughts of air. Pigeons will bear any amount of warmth and like it, but no cold draughts. Often the lofts are over-ventilated. A touch of oil would prevent the eyes from closing at night.

**CANARIES DYING IN A GREENHOUSE (A Subscriber).**—Upon referring to the Journal of September 9th, page 340, you will find remarks concerning Canaries kept in a greenhouse, therefore it will be unnecessary for us to travel again over the same ground. Respecting the loss of your two birds, one of which "has died suddenly without any apparent cause," we should attribute the loss of the birds to the seed becoming poisoned with the excrement from the vermin, for in your letter you further state, "I am much troubled with mice getting in the seed boxes." This gives very little doubt. From your description of the greenhouse we imagine it to be proof against rain and cold winds, especially as it is well roofed, and "has walls on all sides but the south." You will have to declare a war of extermination against the fierce-eyed pests, or you will not be successful with your feathered pets. The birds being kept in an aviary cage will afford you the opportunity of laying traps and poison for the mice during the night time, and to better ensure success each night remove the seed boxes from the cage. We should not advise you to paint the wires—white lead is poisonous. Continuous and excessive dampness will do your birds harm. The place will not be too cold for them.

**CANARIES SHORT OF BREATH (Stamford).**—If the nostrils of the birds are affected or clogged they will show outward signs of humor, but if they appear in a healthy state no outward application will be needed, and there will

be no necessity to pass a small quill feather through them. The "suffocating" or shortness of breath proceeds from the air passages or breathing organs, which have become impaired through cold or influenza. Remove them from the other birds into a spacious cage, and place in a dry atmosphere a few degrees warmer during illness. Let them have grit sand (so that their gizzards may perform their necessary functions), a bath daily, and let all seed be well sifted before supplied. Mix or sprinkle over the seed before giving it a pinch or two of flowers of sulphur. Once or twice a-week give a drop or two of cod-liver oil, and daily let them have as much of the plantain weed to pull as you can obtain for them. It is plentiful just now. A little watercress is good. No sweets, or you will make the breathing more difficult. A piece of salt to peck at will tend to clear their throats. Bisulphite soaked in sherry give twice a-week. Alternate the diet. Keep the birds as quiet as possible, and when you require to catch them darken the cage with a cloth, which will prevent much scolding and excitement.

**CANARIES CASTING THEIR FEATHERS (W. M. Gross).**—In reply to your questions we give the following:—1. The Canary, Goldfinch, Linnets, Mules, and all other cage birds should cast all and every one of their feathers every year after the first year's moult. 2. They throw their flight feathers annually—every one of them—from the smallest of the tertials, which are those next the body of the bird, to the secondaries, which form the middle of the vane, and to the primaries or quills which form the flying feathers of the wings. According to the natural order of things birds should become possessed with entire new feathers once a year. If through artificial temperature a bird should have a partial moult out of its proper season, there is the bare possibility that it will not cast the whole of its feathers as free as one which has not been so subjected. There are well-known instances when birds pass over the autumn or proper moulting time without casting their feathers. Such cases are exceptional and unnatural. Then it is a sign that the system is failing to act properly. The birds are feather-bound owing to a defective state of the blood. When this happens the birds should be removed from the position they may have occupied either into a warmer or colder atmosphere for a few weeks; and if this does not bring about a change or looseness of feather, ten to one the birds' health will become so impaired that they will either quickly die or become lingering sufferers. When birds are healthy and well they begin to get loose in feather the end of June or in July, especially following intense heat. The first symptom is the falling of a flight feather or two on the cage bottom. If you take the birds in your hand and examine them, most likely you will find the sixth or seventh primary quills deficient, and perhaps new ones shooting forth. If the birds should be up breeding it will be useless letting them continue to breed, for the reason that the hen's eggs may become unfertile; and if not, it is unwise breeding from parents when they become sickly. A general looseness of feathers speedily ensues. The most difficult feathers for birds to cast are the two or three extreme flying feathers. Sometimes it is necessary to draw them.

**DRIVING BEES (A Constant Reader).**—Generally speaking there are a few stragglers left. If the hive with these is so placed at the door of the swarm hive (driven bees), the stragglers will run to the noise. Sometimes the brimstone is used to remove those that refuse to leave the comb. In cold weather bees are loth to leave their combs, and therefore difficult to drive. In such weather the combs should be sprinkled with syrup about fifteen minutes before driving; begins. The syrup thus given makes the bees quite jolly, and causes them to run as readily up into an empty hive as they do in summer.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

29th.—Very fine morning; dull about noon; fine afternoon and evening.  
30th.—Brilliant morning; dull about 2 P.M., but fine afterwards.  
Oct. 1st.—Rainy morning; dull and cloudy with showers all day, but not heavy showers; rain at midnight.  
2nd.—Rainy morning; showery all day, but bright at intervals; fine evening and night.  
3rd.—A thorough rainy day, a constant mistle rather than heavy rain.  
4th.—Very rainy at 8 A.M., but cleared off before 11; bright and fine for an hour or so, then cloudy and rainlike; but fair all the afternoon and evening.  
5th.—Cloudy early; fine about noon, and very bright for an hour or two, but suddenly becoming very dark and stormlike; a short but very heavy shower just before 4 P.M., with some hail; fair after.  
A dull damp week, very little sun, and rain almost every day. The temperature generally about 8° below that of last week; but the mean maximum in sun was 7° lower than last week, and 18° lower than the preceding one.—G. J. SYMONS.

### COVENT GARDEN MARKET.—OCTOBER 6.

THE present damp weather is sending large quantities of both house Grapes into the market, which otherwise would have been retarded, keeping prices much the same. We are also well supplied with late Peaches, these being as good as we have known them for years. Peas consist of Marie Louise, Gansel's Bergamot, Louise Bonne de Jersey, and Duchesse d'Angoulême; and of Apples Ribeton, Cox's Orange, and Blenheim Orange Pippins. A cargo of St. Michael's Pines arrived during the week, but in very bad condition.

From observations taken near London during forty-three years, the average day temperature of the week is 59.2°; and its night temperature 40.5°.

From observations taken near London during forty-three years, the average day temperature of the week is 59.2°; and its night temperature 40.5°.

## AUTUMN WORK.

**W**HAT a relief to the flower gardener to bid farewell to the summer of 1875—if such a season as we have had is worth the name—when all his ingenuity, his time, and strength have been exhausted in an ineffectual attempt to produce something like harmonious colouring! The work has been quite double to that of ordinary seasons; weeds and grass have grown as they never grew before, while the more tender plants in beds have scarcely grown at all. Now and then we had a gleam of sunshine to cheer and encourage us to make another effort, and again and again as soon as we began to get a little tidy came a thunderstorm or a hurricane, thwarting all our attempts at neatness. Gardeners, however, never give up for trifles, and it is not till October is here that we acknowledge ourselves beaten.

The trees are now putting on their autumnal tints; Elms and Tulip Trees are being arrayed in the brightest of gold, by the side of which our so-called Golden Feather and Golden Chickweed pale into a sickly green. Maples, Scarlet Oaks, and deciduous Cypress quite reconcile us to the loss of our Alternantheras and Iresines. The delicate tracery of our carpet beds, so much admired a short month ago when the woods were verdant, is very insignificant now when we look beyond them and catch a glimpse of the timber-covered hills with such bold masses of brown and gold.

Leaves of every hue are playing about in the gentle breeze as they fall to rustle beneath our feet. What a mistake to run after every leaf with a barrow and a besom as it falls! what a waste of time and a want of taste! Gather them up certainly before they begin to decay on the walks and so discolour them. But, employers, please remember that October is a month in which trimness is impossible out of doors, and if it were not impossible it would still be undesirable. And there is another reason for not insisting on too much trimness in October; it is a month in which the professional gardener has two seasons at once. In one respect his new year begins somewhere about Michaelmas, the same time as the Russian Violet commences flowering. Forcing has to be prepared for in earnest, planting pushed forward with all possible speed—evergreens first, and fruit trees immediately afterwards. Pruning has also to be finished, with the modern gardener, before Christmas, and where there is much to do must be commenced with early. Currants are already fit for the secateur, Gooseberries will shortly be, then Plums, Morellos, and Peaches. After the principal leaves are ripe the sooner such trees are pruned the better.

The secateur, or French pruning-shears, is a very handy little instrument; its total length is about 9 inches, and its weight half a pound. It can be gripped with the whole hand, and consequently does not tire the operator like the ordinary shears; it makes a cut as clean as a

knife, and by its aid the pruner can do his work much faster than with a knife. No one having used it for one season will go without it till a better instrument is invented, which will probably be some time first.

Digging, trenching, potting bedding plants, planting Box-edges, laying turf, storing fruit and vegetables, sheltering tender plants, and a multiplicity of other things too numerous to write of, all want doing now, and it is altogether an exceedingly busy month.

Gardeners generally have a comparatively leisure time of it during August and September. They are enabled to look round themselves at home, and often to make a little tour and pick up useful hints from others of the fraternity; they then begin about October with renewed vigour to work for another year. This year, however, I know many have found it impossible to keep up with their work, and consequently anything like relaxation has been out of the question. This continued-unbroken work is already telling severely on several strong and able men of my acquaintance, and I have no doubt that many more yet will suffer from it. The work is so exciting and so intensely interesting that it is almost impossible for an enthusiast to think of his health while he is behind with his work, and consequently many go on till nature can no longer stand it. I would ask employers, then, if they happen to possess a good and enthusiastic gardener whom they value, to be careful just now and not tax him too much, for there are some hundreds at this moment who if they had another straw placed on their backs would break-down. But enough of this.

Autumn is here. Bright and breezy autumn, I give you a hearty welcome; you shut out of sight for ever our dismal wintry summer; you release me from floricultural millinery, and put an end for a time to my polychromatic disappointments. I go to enjoy my vacation with a spade and a pruning-hook, for the most perfect rest is a change of occupation.—WILLIAM TAYLOR.

## RENOVATING VINES.

By going the right way to work, and setting about it at the right time, it is surprising what great improvement may be made in Vines which are apparently approaching dissolution. I know no plant so tractable as the Vine, and none which answers to the whip, so to speak, so promptly and clearly. Vine borders may be renewed at almost any period of the year, and the roots be taken from an ungenial soil and placed in fresh compost, providing due care is exercised in the work and a correct system of treatment is subsequently given to the Vines by shading, temperature, moisture, &c. The easiest time, however, to do such work is during the present month, before the Vines have cast their foliage, and before the soil has parted with its summer's heat. These are two important conditions, and both are essential to the speedy re-establishment of the Vines.

A few years ago I found it necessary to lift the roots of some old Vines, and my employer found it necessary to warn me that he should expect a crop of Grapes the

following season. The Vines had been bearing fairly well, but each year were losing vigour, and the time of their complete failure was evidently not far distant. I was in a fix; I dare not sacrifice a crop, yet to defer operations of renewing the border was simply waiting for the dreaded year when the Vines would be barren. I resolved to act. I had the new soil ready. It was fresh loam without any admixture. I coveted bones, but they were not to be had; so in their stead I made charcoal by burning all the rubbish I could collect, including the (I may as well confess it) surreptitious use of my employer's firewood.

I then took out the border, and kept the old bare roots moist by syringing them, brought in the fresh soil, and lifted them from their bed of cold clay into one of warmer drier loam. I did not cut them—at least I allowed the point of the main root of each Vine to remain deep down I know not where, still lifting the other part of it as near to the surface as it could be bent. The smaller roots I cut. The main roots I notched at 2-foot intervals, and severed them more than half through at the extremity of the border where they entered the bed of the gravel walk. Each of these roots I surrounded with charcoal, enveloping them 2 inches in thickness on all sides. I covered them with 4 inches of soil and 6 inches of manure, and the work was done. The foliage was on the Vines, and I wished to keep it there to induce the emission of fresh roots. I therefore syringed—autumn though it was—and kept the house somewhat close. The Vines were eventually pruned, and in the spring they broke with their usual weakness; they, however, gathered strength daily, and ripened a finer crop of Grapes than they had done for ten years before, although every particle of soil was taken out of the border in the previous autumn.

In the summer the roots were examined, and bristling from their surface both at the notches and between them were thousands of fat-looking spongioles. I have proved the value of charcoal in many ways, but I never saw such a satisfactory instance of its virtues as in drawing feeders from these fibreless roots. The extremities of the main roots were then severed, and a network of feeding roots permeated the border. These are near the surface, and I intend them to be kept there by annual dressings of manure.

The change was magical. Young canes were trained up, and a new lease of life was given to the old Vines. They had been planted thirty years when their renewal was effected, and certainly they have never been in such a good and satisfactory condition as they are now. My employer is especially proud of them, perhaps more so than I am. He is sensible enough to be satisfied with a great number of one-pound-weight bunches having large black berries, while I am vain enough to covet a few monsters such as we read about. He has ever been firm in refusing me permission to train thinly, crop lightly, and create a sensation, and perhaps he is right, for perhaps I should fail.—A NORTHERN GARDENER.

### PENTSTEMONS: THEIR PROPAGATION AND CULTURE.

PENTSTEMONS are amongst the most beautiful of border plants, and the present is a good time to propagate them. It may not be generally known that the treatment which is usually given to the bedding *Calceolarias* is almost exactly applicable to Pentstemons. It is preferable, however, to put in the cuttings of Pentstemons a little earlier than those of *Calceolarias*, although they will flourish fairly well if inserted at the same time and under precisely the same treatment. I have been uniformly successful in raising Pentstemons by inserting the cuttings early in October by the aid of cold frames alone, and these of the rudest description. These have merely consisted of inch boards set on edge and made firm by stakes, and covered with spare lights. Such boards a foot in height at the back and 6 inches in the front afford a sufficient fall for carrying off the water from the lights, and these rough enclosures are useful for many protective purposes. They are easily covered in the winter with straw, and the plants or cuttings in them are always near to the glass. They are, however, at the best only makeshifts, and only permissible in the frame ground—the back kitchen of the garden—and for appearance sake and general efficiency the low structures manufactured by the advertisers in the Journal are in all points preferable, and should have a place in all gardens.

In striking Pentstemons in these rude enclosures my practice

has been to take out about 4 inches of the soil and replace with a compost of loam and leaf mould in equal parts, and surfaced with sand. Before putting in the soil, however, a layer of soot should be spread, which prevents the worms working upwards, and also affords a stimulant for the plants when they become rooted. The cuttings selected must not be those which are soft and such as would strike in heat readily, but short-jointed semi-woody side shoots, which will flag but little and damp-off scarcely at all after they are inserted. The cuttings inserted 3 inches asunder will neither need repotting nor transplanting before transferring them to their blooming places in April. After being put in it is necessary to shade them during bright weather, and sprinkle them occasionally—in fact they must be kept close and not be permitted to flag. If properly selected and carefully tended very few fail to strike and make fine blooming plants during the summer and autumn months.

In order to grow the plants well the soil must be rich and deep, and the plants need copious supplies of water during dry weather. They are moisture-loving plants, and are generally finer in Scotland than in England owing to the heavier rainfall and cooler temperature of the north. For large beds or rows, as well as for isolated plants in mixed borders, they are beautiful and effective, their glossy foliage, agreeable habit, elegant spikes, and fine *Gloxinia*-like flowers, being a combination of claims which few plants possess.

Great improvements have recently been made in Pentstemons, and each year new varieties are being added to our collections. They are offered in almost all colours, and named collections should be included in all gardens. The present is a good time to secure plants from the nurseries, where they are now rooted and established in thumb pots. These, if shifted into pots two sizes larger and plunged in ashes, and kept safe from frost, will make handsome blooming plants in the forthcoming season.

As plants which can be kept from year to year without the aid of artificial heat, they are adapted to those with moderate conveniences, and cannot fail to be enjoyed by all when seen under good cultivation. They have been much admired in Battersea Park this year, and doubtless we shall see them employed at the Crystal Palace, where plants of every rank and degree appear to be embraced in Mr. Thompson's comprehensive and able management. The more general cultivation of Pentstemons is cordially recommended.—A SURREY GARDENER.

### PEAS.

MR. LAXTON's name will be indelibly written on the page of horticultural history as the raiser of many varieties of Peas of great excellence.

In spring I had sent me for trial four small packages of Peas, and I now somewhat tardily acknowledge their receipt by recording my experience of them in the columns of this Journal. They were sown and treated the same as other older kinds, and adjoining them for facility of comparison. Pampering and giving special culture may bring out merit, but I prefer that a new vegetable be proved under ordinary treatment, and to stand or fall by that treatment to which they will be eventually subjected. The Peas were Unique, Dr. Hogg, Supplanter, and Connoisseur. I sowed them all on May 4th, and all came up strong.

*Unique*.—This was stiff in growth, and commenced flowering when only a few inches high, podding near the ground, growing to a height of 18 inches, being a dwarf grower, very prolific, larger in pod and pea, also better filled as well as earlier than *Little Gem*. The pods were of a bright green colour; the peas about eight in a pod, of a deep green colour and of excellent flavour. The crop comes in all at once and not successively, which is a consideration in growing dwarf Peas, as the ground can be cleared at once and planted with other crops. *Unique* is unquestionably the best dwarf Pea in cultivation, more prolific than *Little Gem*, and of superior quality to any of the dwarf kinds. It will be found an acquisition for small gardens, for growing in pots or forcing, and in front of walls for early crops.

*Dr. Hogg*.—This had pods fit to gather at the same time as *Unique*, but a very different fitness to that of that variety; for whilst *Unique* was over in ten days, *Dr. Hogg* had pods fit for use after thirty days. It and *Unique* had pods fit to gather on the 16th July. *Dr. Hogg* is therefore an early kind, and possesses the continuity of bearing of *Ne Plus Ultra*. The pods were 5 inches long, of a dark or blue green, slightly curved

and very handsome, containing usually nine peas of a very fine dark green colour. It attained to a height of 5 feet. A fine Pea, the earliest and best of wrinkled Green Marrows.

**Supplanter.**—This is very robust, and attained to a height of 4 feet, having very large pods 6 inches long and correspondingly broad. Peas large and of a rich green colour; and though it is of the Imperial class it is fully half wrinkled, possessing a quality equal to any of the latter class, being a large, handsome, and very prolific kind that will supplant many others. The first pods were fit to gather the 18th of August, being nearly a month later in this instance than Dr. Hogg, and it continued in use up to the early part of September.

**Connoisseur.**—This attained to a height of 8 feet and is growing yet, having the rambling growth of *Ne Plus Ultra*. It commenced podding at 2½ to 3 feet from the ground, and producing twenty and more pods upon a stem. The foliage is deep green and enduring, which gives a kind of evergreen appearance to the rows—i.e., plants and seed, being green and having very great resemblance to *Ne Plus Ultra*, but the pods are straight and well filled with about seven good-sized peas of the highest excellence. It is more prolific, more continuous-bearing, and decidedly as a late kind superior to *Ne Plus Ultra*. It had pods fit to gather the 1st of September, and has now (September 28th) upon the same plant pods with ripe seed, some fit to gather, others just slated, and also flowers, which will give an idea of its continuity of bearing.

Now, by omitting *Unique* we have from a sowing of Peas of three kinds—viz., Dr. Hogg, *Supplanter*, and *Connoisseur*, made early in May, a succession of Peas from the middle of July into October. Such a trio for excellence as I have not found before; whilst the dwarf one, *Unique*, is essentially an amateur's Pea of the first cropping and using quality.—G. ABBAY.

#### NEAR AND AMONG ANTEDILUVIANS.—No. 2.

RAPIDLY becoming antediluvian—that is, things of the past—are country pleasure fairs; that of Lyme Regis was on the 5th inst. and two booths for the sale of toys and sweetmeats then comprised the whole! The useful portion of this annual gathering retains its full vitality. Householders lay-in their winter store of Onions on that day, and garden-holders buy the Cabbage plants which are to yield their spring supply. The Onions are sold in "bags," each bag containing six pecks, and hundreds of bags were there. Pickling Onions sold for 10d. the peck of 14 lbs. The best store Onions, averaging 3 inches in diameter, sold for 7d. the peck. The Cabbage plants, a large-hearting variety, were 6d. per hundred.

I have now journeyed over a semicircle round the town having a radius of ten miles, and in all directions the cottage gardens are worthy of praise. The flower beds even at this season are gay, for Fuchsias, Geraniums, Hydrangeas, and Myrtles remain in the beds throughout the winter. Many hedges of *Fuchsia Biccartonii* are to be seen in superior gardens, and single shrubs of it 10 feet high with branches covering a circle of 8 feet diameter. Myrtles are also tall shrubs, and are now in flower.

Other plants which in colder districts are dwarf shrubs, or require the shelter of a wall, are here tall standards. I have just seen a Fig tree, a 20-foot-high standard, with 6 feet branches all round, and a stem 2 feet in circumference. It is loaded with fruit nearly full grown, and which will ripen if this month prove sunny, and if it prove unpropitious the fruit will be fit for preserving. The Holly is more than usually employed for hedging round fields as well as gardens, but it is only on its tree-growth that I wish to note. Holly trees are frequent and noble both in size and vigour. One close to the town is 50 feet high, its single stem more than 3 feet in girth, and its branches shade a circle of 20 feet diameter. Portugal Laurels, and, indeed, all hardy evergreens, are of superior stature and vigour.

I dwell in my previous notes upon that unique plant "The Flower of the Axe." Among other plants rare in the neighbourhood is the insect-devouring *Drosera*, rendered more notorious recently by Mr. Darwin, and the Bog Pimpernel. The Primrose is here common, but the Cowslip is scarcely known, and is popularly called "the Crewel." This and other local names of plants induced me to hope that among them might be the mysterious "Culverkeys," but no plant is known here by that name.

The Apple orchards are most numerous, and the crop this year very large. From here down to the valley of the Axe is the locality where the best cider is made. The crushing has

commenced, and I have seen cartloads of Apples being taken to the mill.

As I write cartloads of seaweed are passing the window, and they continue passing all the day, and every day except Sunday. The supply is inexhaustible, for every tide throws it up into an accessible cove behind the solid stone Cobb, or pier as it would be called elsewhere. The seaweed is chiefly spread over the grass land at this time of the year, but it is used as a foundation for the compost heaps. In the garden it is especially liked for Cabbages and Potatoes. One gardener tells me that it is spread thickly beneath Gooseberry bushes to prevent the caterpillar.

As might be expected from Sir Walter Raleigh's connection with, and the trade with Spain being largely carried on along this coast, it was one of the earliest to cultivate the Potato extensively. Ohard was, and still is, one of the largest markets for it. The commonalty at first had a great prejudice against its use for food, and they thought that the higher classes had some sinister motive in promoting its growth—no fact could show this more forcibly than the election cry at Lewes, "No Popery! No Potatoes!"

The word "Popery" reminds me that I have just been to the church here—though nothing can possibly be further from decoration than that—but it enables me to jot down that in the nave there is an epitaph on one of the Roses, contemporary with him who was Charles II.'s gardener. It is in memory of Elisabeth Rose, and it includes this anagram, "Ohe! blest arise." Totally differing in every respect is the church, and all its surroundings of Monkton Weald, a good old Saxon name, and going thither I passed an inn with a sign, probably the only one in all England. It is the "Pen Inn," so called, not in reference to the writing implement, but because it is on the top of the hill, Pen being the Saxon for a summit. The parsonage, the churchyard, and the church are all models worthy of general imitation. The incumbent, the Rev. J. B. Camm, is known to the readers of this Journal as a skilled rosarian. His Rose beds on three descending terraces are occupied by about two hundred standard, and a more than equal number of dwarf Rose trees. Far away on the other side the churchyard is the Rose nursery. Hundreds of this year's budded standard stocks looked like a miniature Hop ground. Much did I regret that my visit was not in the season of Roses. The parsonage is on a hill side, and the terraces follow at different levels down the hill in its front. The little side gardens, filled with Geranium beds, and surrounded by lofty Hollies, the beautiful specimens of Conifers, the Magnolia, Cotoneaster, Fuchsia, and Tea Roses, covering the house front, are all impressed on my memory, but should be shown by the pencil.

The churchyard has no common-shaped gravestones, but all have neat memorials, alternating artistically with small flower beds. Roses, Gladioluses, Phloxes, and Heliotropes were its blooming tenants when I was there; but there are successions for other seasons, and a purple Clematis and a Passion-Flower are on the church wall. These all tell of happiness to those gone on before, whilst the Cypresses and Weeping Willow of the boundary are fitting for those they have left behind.

There and everywhere the harvest thanksgivings have just concluded—gladdening all, for all feel the gratitude that they are instituted to express. The interior of all the churches have been in some mode decorated, and I will slightly detail the decorations of Beaminster church as an illustration: The reredos had an elaborate course of Barley, Dahlias, scarlet Geraniums, and foliage across the top, and in the centre underneath there was a cross of white Roses, bordered with a design in corn and flowers. Two miniature sheaves of Wheat tied with scarlet Geraniums stood upon the communion table, and there were two more on the communion-table steps. The organ screen had an artistic adornment composed of Wheat-ears, flowers, and fruit, interspersed with Ferns and variegated foliage, and the reading-desks and lectern were similarly embellished. Each panel of the pulpit was marked out with a blade of Indian Grass, and filled-in with vases of Moss, five in number, containing handsome bouquets of flowers, and at the top and bottom were wreaths of Wheat-ears, Apples, flowers, and foliage, from which Grapes were pendant. The font was covered with white Roses, Oats, and Barley, and at the base were placed small sheaves of Wheat and pot flowers. All the gas standards were adorned with Indian Grass.—G.

**STRAWBERRIES.**—On Thursday the 30th of September, and on Monday the 4th of October, there was gathered from my

garden a good dish of Strawberries, the colour perfect and the fruit of excellent flavour. The Strawberries were from plants of the Vicomtesse Héricart de Thury.—E. G. H., *South Norwood*.

#### A FEW CHOICE BRITISH PLANTS.—No. 2.

Resuming my remarks on this subject, I select the following as worthy the attention of collectors and cultivators of hardy plants:—

*Saxifraga oppositifolia*.—This pretty low-growing plant I confess never to have met with in a wild state, although I have sought for it where it was said to exist. Its merits, however, as a rock, or what is called an alpine plant, are too well known to require further notice here. It is a gem in its way when it can be induced to thrive, which it will not always do; and there are many, who preserve their Geraniums and other pets by the thousand, fail to save this hardy denizen of our highest mountain tops.

*Lycopodium Selago* (Fir Club Moss).—This conspicuous plant I remember gathering when ascending one of the Cumberland hills in winter. It was standing up-erect on some bare patches of grass with all the sturdiness of a lilliputian tree, and protected by its peculiar medical qualities from depredation from sheep and other mountain animals, whose sagacity in understanding what is bad for them far exceeds that of our lowland-bred cattle or sheep. I believe Dr. Hooker ascribes violent poisonous powers to it, as well as some of a useful kind in dyeing or fixing colours. It is needless here to say that the sharp eyes of the botanist are required to discover its flower; but its Spruce-Fir-tree-like growth of about a foot or more high gives it a conspicuous appearance, and as a plant it is well deserving of notice. I do not know how it comports itself under cultivation. Most likely, like many other denizens of great elevations, it may refuse to thrive.

*Cyclamen hederifolium*.—I have frequently been assured by those who have met with this plant in a wild state that it seemed plentiful enough where it was found, but I have never had the good fortune to discover it. It has, however, been found in Kent, and notably in larger quantities in Cornwall. I am told it is but seldom met with there now, the denuding of woodland that was once its favourite haunts having tended to render this plant more scarce than it ought to be. Neither is it so generally met with in cultivation as its merits deserve; and it would be well if those who are fortunate enough to find it in a wild condition would note such particularities about its site, character of the soil, and other matters as would be of service to those who try to grow it. In an ordinary way it grows and flowers well enough, but either the seeds lack vitality or they require some other mode of treatment than that usually given them.

*Orchids*.—I fear I must leave to others the task of dealing with these, as I have had comparatively little acquaintance with them, and I believe the attempts to cultivate these have not on all occasions been successful. I need hardly say they are all most beautiful, the early purple Orchis putting to shame the best coloured Hyacinth that can be produced at the time; while the Bee, the Fly, and Spider Orchis have all their admirers for their structural beauty, and the others are not less so, while the one called Ladies' Tresses is a great addition to a Nosegay. I fear, however, I can give no practical hints as to their cultivation beyond the meagre one that chalk would seem to be wanted for many, but perhaps not for all.

*Armeria vulgaris* (Common Thrift).—This is plentiful in certain places by the seashore, especially on a rocky one. Used as edgings it is a highly ornamental plant, and either in flower or not it has a neat compact appearance. But accommodating as Thrift edgings are, they are not so much so in shady dark situations as London Pride (*Saxifraga umbrosa*), which is about the best live edging I am acquainted with.

*Water Lily*.—I am not sure whether anyone would contradict me if I were to affirm that this is the prettiest flower that grows. The Rose may possibly take offence at the assertion, because that generally acknowledged queen of flowers appears before us in so many garbs, whereas this queen of another realm still holds by and retains her original loveliness, which it would be difficult for the artist to improve.

*Heath*.—Like the last, poets, historians, and writers of romance have made this plant theirs through many generations, and the beauty of the ordinary one is perhaps not excelled by those more rare. It is a plant, however, that I would not advise removing to the formal parterre, neither to dressed ground anywhere; but it may with advantage be introduced

into rough shrubbery or other suitable sites. Possibly, however, the early-flowering Cornish species might have a place in the fashionable garden; but as the whole family prefer not to be shifted too often, it would be as well to give it a permanent position if possible.

*Primroses*.—I here only allude to the wild kinds, which at some future time may possibly be more numerous and varied than at present. A good deal has been done in the way of hybridisation, some of them with garden kinds, and we all know their accommodating character. The outcasts from gardens have already spread many pink and other dark-coloured flowers amongst them. The more general distribution of the Oxlip and its liability to merge into the Cowslip and Polyanthus are matters known to all, and may possibly end in great diversity of this plant.

*Lily of the Valley and Solomon's Seal*.—Both these are doubtless British plants, but more generally met with in cultivation. The first-named species in a wild state is seldom met with in such good form as it is in cultivation, leading to the inference that the latter is an improved variety. Comment is unnecessary on either.

*Oxycoccus*.—This is a most useful family of spring as well as autumn flowers. They are all, however, more regarded as of foreign extraction than of British origin. In planting them on wild places we have so often had them destroyed by mice that but very little care really has been made of them. The autumn Crocus usually escapes the mice.

*Foxglove*.—Nowhere is this plant so pretty as when found wild, and no plant can possibly look better than it does in the position it is often met with.

*Toad Flax*.—Both the hanging and upright-growing species of Linaria are pretty and deserve attention; while in connection with them the Snapdragon is often met with apparently naturalised, and flourishing on some wall or rockwork natural or artificial.

*Lythrum salicaria*.—This stately plant, growing as it does by the sides of ditches, is one of the prettiest we know of late in the summer, rising to the height of 4 feet or more with its closely-set spike of rose-coloured flowers. It is a striking object, and well deserving attention.

*Myosotis*.—As the garden species or variety—for it is no easy matter to distinguish the one from the other—is more easily managed than the wild, it is not necessary to encourage the latter, unless it be *M. palustris* by the side of some ditch or pond, where it yields to none for beauty; but its flowers are less plentiful than the garden variety called *M. dissitiflora*.

*Saintfoia* is a very pretty plant, as likewise is the field crop, *Trifolium incarnatum*. The latter, however, is not a British plant. Dry chalky soils suit both.

*Pyrola media* is a pretty-habited plant usually met with in Fir plantations on rather a stiff soil. Both flower and foliage are good.

*Rhinanthus Crista-galli* (Yellow Rattle) is not by any means an unsightly plant, while the flowers are really showy. Pasture or rather meadow land, on rather a stiff soil, seems to be its home, and in England it is thought to indicate the time for cutting the hay when its seeds rattle in their pod. In Sweden the hay is mown when it is in flower.

*Sedum acre*, and some other species, are more or less in demand now that dwarf plants are sometimes wanted. There are several varieties of the first-named all produced by cultivation, but the original is likewise pretty and interesting.

*Spiraea ulmaria*.—This would have been considered a handsome flowering plant if it had been imported from some tropical clime and was difficult of cultivation, but as it is no one can deny it the claim of beauty. There is a golden variegated form of it very pretty, but it is of slow growth.

*Thyme* (Wild) looks very pretty when it covers the ground and throws up its lavender-coloured flowers in profusion. A dwarf form, not British, *T. micans*, is very handsome and pretty as a dwarf plant.

*Trollius europæus* (Globe Windflower).—I am not certain of having found this plant wild, but I know it has been found so in moist rather exposed places.

*Callitha palustris* (Marsh Marigold).—Foliage and flowers are alike pretty. As its name implies, the margin of ponds or rivers is its home.

*Valerian*.—Nothing can possibly exceed the beauty of some of the chalk cuttings and embankments by the sides of railways in some districts where this plant abounds. The most carefully cultivated flower bed does not exceed it, and it is found in such abundance, too, attracting the attention of the

most careless passers-by. It will grow in most places, but reproduces itself in greatest abundance by the sides of railway embankments where chalk abounds.—J. ROBSON.

### WHEN TO PLANT FRUIT TREES.

It is generally conceded that autumn is the best period for the removal of trees and shrubs. I will not dispute that it is so, but at the same time I am of opinion that trees may be moved any month in the year if care is exercised and correct treatment is subsequently afforded them.

Early this spring, in consequence of alterations, it was found necessary to remove some Peach and Nectarine trees which had been planted seven years. These trees I removed on the 28th and 29th of April, and I have since gathered from them an excellent crop of fruit. They were removed with great care and planted against some spare places on a north wall. On this aspect they have not only ripened their fruit, but it was ready at the usual time. Malta Peach was gathered in the middle of August, and Bellegarde the last week in September. I can only account for this early ripening on a north aspect to the fruit having been set early and the regular attention the trees have received in syringing and watering them. These trees will be removed to a south wall, but to have put them there in the first instance would have ended probably in their destruction.

Shortly before moving the Peach trees I removed some pyramidal Pears of large size and full of fruit. These trees were taken up and replanted with great care. Fresh soil was placed round their roots, and the foliage was syringed several times a day for some time. These trees have perfected finer fruit than ever they have borne before. I attribute success in these instances to the care taken in not mutilating the roots or suffering them to become dry during the operation of removal, to the fresh soil given them, and to the frequent syringings to keep the foliage fresh.

Thus it is that I believe that trees may be removed at any period of the year if means are provided to attend to their wants afterwards. These wants are reduced to a minimum in the autumn, and hence it is that planting should be expedited at the present time, and before the earth has become wet by the rains of winter, sodden, and cold. If planting cannot be done early in the autumn I think it well to wait until the ground has become dry in spring. More depends on the state of the soil as to its being in a free easy-working state, and the attention that can be given to the trees, than to any mere date at which it is best to transplant fruit trees and shrubs.—JOHN TAYLOR, *Harbridge Grange*.

### CARNATIONS: LIST OF FOUR OF THE BEST IN EACH CLASS.

*Scarlet Bizarres*.—Admiral Curson (Easom), Dreadnought (Daniels), so much alike that I grow them as one sort; Sir Joseph Paxton (Ely); Lord Napier (Taylor), Mercury (Hexall).

*Crimson Bizarres*.—Eccentric Jack (Wood), Captain Stott (Jackson), Lord Bagin (Bowers), Warrior (Slater).

*Purple Flakes*.—Squire Maynell (Brabbins), Juno (Baldon), Premier (Millwood), Mayor of Nottingham (Taylor).

*Scarlet Flakes*.—Clipper (Fletcher), best; Sportsman (Hedderley), John Bayley (Dodwell), Mr. Battersby (Gibbons).

*Rose Flakes*.—John Keet (Whitehead), James Merryweather (Wood), Uncle Tom (Brammas), Flora's Garland (Brooks).

*Red Picotees*.—Princess of Wales, n (Fellows); Brunette, n (Kirtland); Mrs. Dodwell, n (Turner); John Smith, n (Bowers); Wm. Summers, n (Simonite); Mrs. Bowers, n (Bowers); Mrs. Keynes, n (Fellows); Thos. Jivens, n (Flowdy).

*Purple Picotees*.—Alliance, n (Fellows); Norfolk Beauty, n (Fellows); Mrs. Summers, n (Simonite); Mrs. May, n (Turner); Mary, n (Simonite); Ann Lord, n (Lord); Mrs. Hannaford, n (Simonite); Amy Robsart, n (Dodwell).

*Rose Picotees*.—Mrs. Lord, n, rose (Lord); Edith Dombrain, n (Turner); Rev. H. Matthews, n (Kirtland); Flower of the Day, n (Norman); Empress Eugénie, n (Kirtland); Beauty of Plumstead, n (Norman); Cynthia, n (Lord); Bertha, n (Morris).

Many of the foregoing were shown well at the National Show at Manchester. With regard to a suggestion of the Carnation Show being held on the 13th and 14th of September, it must be a mistake, as all bloom is over with us before that time. The National Show was held on the 13th and 14th of August. Next year it will be held on the 11th of August. The general

meeting to arrange the schedules for all the national shows will be on the third Wednesday in January next, at 1 p.m., at the Old Bull's Head, Market Place, Manchester, when I as one of the Committee, and I have no doubt all the others, would join in welcoming any of the southern growers who might be able to attend. As to fixing a time suitable for north and south that is impossible, but there is nothing to hinder us from having a number of shows every year under the one head (National). I have had some correspondence with growers in other districts who are in favour of holding a show (national) to come off about the 20th of August, which would be a means of giving the late districts a chance. The more extended a national society is the better it is, as it will always prevent the market from being flooded with indifferent varieties.

We always show the blooms on cards, and have done so for the last thirty years. The cards generally used are 3½ inches in diameter. Most of the growers procure them from Geo. Meek, Crane Court, Fleet Street, London. If a flower is small we use a smaller collar in proportion. We are, however, having sorts now for which the 3½-inch collar is none too large.

A few words with regard to dressing. This has always been done ever since I knew anything of Carnations, &c., and if there are any who can grow them well but not dress, I say the sooner they learn the better. All the old growers that I know make no secret of it, but are willing to show anyone. After the National Show, and at the general meeting which took place, a flower was taken and dressed before all present by one of the best dressers in England (E. S. Dodwell, Esq.); at least I have always taken him to be such.—Geo. RUDD, *Undercliffe, Bradford*.

### A VOICE FROM A TOWN GARDEN.

AMONGST the many enemies I have to contend with the most formidable are smoke, sparrows, caterpillars, and an exposed situation. My last sowing of Peas has failed entirely through these feathered depredators; and whole rows of fine Cabbages are fairly riddled by a perfect army of caterpillars. Then the smoke is everywhere, and how to fill up profitably a few vacant spaces in the garden and on the walls is an enigma too hard for me to solve. Will someone kindly come to my assistance?

I have somewhere read that where Black Currants flourish Raspberries will do so likewise; but I have not found this to be the case. I have, perhaps, half a dozen Raspberry canes, from which I have sometimes gathered about as many Raspberries. It has been suggested that they are too far apart, but would that make any difference? If so, I will at once proceed to fill up the spaces, and should be glad to know what are the best sorts. Red Currants bear here, but not so abundantly as the Black, and are small and not very juicy. Gooseberries I can do nothing with. I have one Walnut tree which has sometimes borne a few hundreds, but from the Filbert bushes I have never had a single nut. Apples do no good, though one or two old trees bear a few most years, Northern Greening and Keswick Codlin for instance; but these are gradually dying down, and the few young trees I have planted are infested with American blight every season.

With Pears I am more fortunate. A standard Jargonelle has borne plentifully this year, having before always failed, though a free bloomer, from late frosts, being in an exposed situation. Of Pears against a west wall I have a tolerable selection. One, Knight's Monarch, bore well last year for the first time, though twelve years old; but this spring it was attacked with a grub—which indeed attacks all the fruit trees more or less—every leaf and bud was eaten away, and the tree is now dead. I should like to replace it, and what sort would be best to have? The trunk of this tree, and the trunks of most of the others, looks rough and cracked, and our gardener says it is a bad sign, and shows that all are in a bad way. The sorts I already have are Beurré Diel, which has never borne; Beurré de Capiaumont; Beurré de Bance, never borne; Louise Bonne of Jersey, Napoleon, Williams's Bon Chrétien, and Glou Moreau, never borne. One of these, a small tree that makes but little growth, bears well most years. The fruit is ripe now, but having lost the label I cannot tell which it is. It has a fine ruddy colour on the side next the sun, pale yellow when ripe on the other; fruit rather long, tapering towards the stem, and not very large. Does this description point to Louise Bonne of Jersey, which I rather think it is?

From Pears to Roses is a wide step, but I have one—a Tea-scented, I think Gloire de Dijon—which after making little

visible growth during the spring suddenly shot-up one long stem, which bore one very fine blossom quite at the end, and a small imperfect one on a lower branch. The new branch is at least 4 feet long, and looks straggling and awkward. Should I cut it down? And should Roses generally in such a locality be cut short at this time of year? I have tried in vain to find a good crimson climber. Before I close let me recommend, as one of the very best yellow bedding annuals I know, *Tagetes signata pumila*. It is at this time a perfect mass of colour, and grows compact and very bushy, making a most showy bed.—A LADY GARDENER.

[This is the letter of a true gardener—one who clearly loves her garden and will not willingly succumb to adverse circumstances. It is such earnest workers whom we are especially desirous of aiding. In a smoke-polluted atmosphere the only antidote is the water engine; by its aid and a judicious selection of plants a smoky garden may be made fairly enjoyable. Sparrows may be dealt with in two ways; one is to destroy them, and the other is to feed them. If they are fed regularly in a place distant from the garden a great deal may be done in preserving the crops. Peas should be protected. In the absence of regular "protectors" (which are cheap and efficient) lengths of closely-woven hexagon wire netting bent over the rows will answer the purpose admirably, and will completely baffle the birds. Caterpillars (in this instance the sparrows have not eaten them) can only be kept down by hand-picking. This may be done, and should be in young plantations of Cabbages. A mixture of soot and lime to be dusted over the young plants occasionally is also recommended. Black Currants and Raspberries are alike in requiring a moist soil, and both will endure some shade, but the latter do not flourish so well in a town garden as the former. Closer planting will not induce fruitfulness (the canes are worn out), but a fresh plantation from a vigorous stock might produce fruit for a few years. Carter's Prolific is a good and robust-growing sort. Raspberry canes are short-lived in town gardens, and need frequent renewing. Filberts are not adapted for town gardens, and are never profitable. The American blight on the Apple trees may be destroyed by dressing the parts affected with paraffin. This must be done in the winter. The unnamed Pear is *Louise Bonne* of Jersey. Fill the vacancy with a duplicate tree of the sort which has been found to flourish the best. Are the trees too full of wood? The one "which makes but little growth bears." If the branches are thick the growth is gross by each shoot struggling to obtain air. The branches must be thin, so that the sun can shine quite through each tree, and if after that they continue to grow too luxuriantly cut some of the main roots. Prune the Rose to one-third its length of young wood, and all the Roses should be encouraged to grow strongly by liberal supplies of liquid manure to the roots, and frequently syringing the foliage, and they should be pruned short-in in the winter. *Amadis* is a good crimson climber. Is not the surface soil of the garden light and poor, and the subsoil strong and wet? Rich surface dressings and liquid manure at any season should be given to the Raspberry canes and Roses. Mulch also to induce surface-rooting of the fruit trees, for surface roots produce fruitful wood, but subsoil roots create an excess of robust shoots and foliage, which is not conducive to fruitfulness.]

#### PEACHES INDOORS AND OUT.

ENCLOSED is a Peach grown on a standard out of doors; the tree has had no protection, and was removed out of my orchard house, after the wood was ripened, in October, 1874, where it had ripened a crop of fruit very much larger but not so high-flavoured as they are this year. The tree has ripened all its fruits this season; all exactly the size of the enclosed specimen. It is planted in a bed having a westerly aspect and gravelly soil two miles south of Birmingham, and nearly 500 feet above the sea level.

I have found that anything which checks luxuriance is conducive to fruitfulness: the replanting would do so. Some of my labels were tightly tied with fine whipcord, and cut deeply into the branches; these branches alone bore fruit on several of the trees when young. My practice is not to water Peaches, Nectarines, &c., from October (when they have several hundred gallons) until the fruit is set; the young fruit then adheres very firmly, and shows no tendency to drop off.

There are twenty-five trees in my orchard house, each from 8 to 14 feet in diameter, and all with only one exception bore a good crop. This season the glass is butted instead of being

lapped, which admits the dew as well as more air than the old plan, hence I think my success.—THOS. A. BICKLEY.

[The fruit sent was perfectly ripe, but we could not test its flavour, as it was smashed.—EDS.]

#### THE POMEGRANATE.

THE Pomegranate (*Punica granatum*), although it does not produce its fruit in England, is exceedingly attractive by its beautiful scarlet flowers, which it produces freely on warm south walls in the southern counties. It is generally, however, sparse in flowering, a consequence in most instances of over-luxuriant growth by rich soil and extreme moisture at the root. Where the site is warm, and the soil dry and rather poor, this plant will generally flower freely under careful cul-

Fig. 72.—*Punica granatum*.

ture and a correct system of pruning. The branches should be thinly disposed, so that the foliage of one does not overlap that of the next, and the lateral growth should be weak and stubby. If the lateral growth is robust no amount of pruning will result in blossom, for each cutting only causes stronger growth and more unlikely blooming-wood being produced. In most cases where bloom does not appear the remedy is to be found in root-pruning. This in connection with a free thinning of the branches is almost invariably the means of inducing the formation of blossom buds and a profusion of the coveted scarlet flowers.

In pruning much the same treatment as that given to the Apricot will be correct—that is, by pinching the young growth in summer, and admitting the sun to every part to mature the wood. But still this pinching must not be excessive, for if the shoots are so strong as to require continual pinching it is plain that root action is too vigorous, and it is at the root that the check must be given. If the breast wood of the Pomegranate grows more than 6 inches in length it is seldom that

blossom is produced, while stubby shoots of half that length almost invariably flower if the temperature is sufficiently high to mature the wood. The Pomegranate is, apart from its flowers, ornamental by its bright green Myrtle-like foliage.

It is adapted for pot culture, and is extensively used as a terrace plant in continental gardens. It requires the full force of the summer's sun, and to be kept rather dry at the roots in autumn and through the winter, when it will generally flower freely. The fruit of this plant is imported from the shores of the Mediterranean, and varies in size and quality. The pulp is pleasantly acid, and is used for the same purposes as the Orange. The bark and root are used for medicinal purposes, and in countries where the tree abounds it is used for tanning leather.

A poor soil, warm site, and thin training of the shoots are the main points to be attended to in cultivating the Pomegranate in England.

#### GRAPES AT THE EDINBURGH SHOW.

MR. DICKSON in his letter distinctly says that he saw and examined the bunch of Grapes from Eskbank, and that it was two bunches, also that six of the best Grape-growers saw and believed the same. If this is correct (and as yet I must believe it is, for Mr. Curror in his letter did not deny it), I think it is the duty of the Secretary and Committee of the Show to make a most searching inquiry into the matter.

It is natural enough to suppose that if the Eskbank Grapes were only one bunch Mr. Curror would have come forward boldly and publicly denied the accusation, but instead of doing that he merely says that the "character and position of the gentlemen who acted as judges are sufficient guarantee that nothing was wrong." That is no denial. No one doubts the honesty and character of the gentlemen who acted as Judges, and no doubt if they had discovered that it was two bunches they would at once have disqualified it; but in the hurry and generally short time that judges have to do their work (and on this occasion in a singularly dark room), they might easily not observe whether it was one or two bunches, for judges are not there to act as detectives, but to award honour to whom honour is due.

Another thing worthy of remark is contained in the letter from "AN ENGLISH GRAPE-GROWER"—viz., that "the Arkleton bunch was much rubbed, and appeared to have received injury in transit;" now, I know for a fact that the bunch was, when it was laid on the table at Edinburgh on Tuesday night, in splendid and perfect condition. As "D. E." appears to have been present at the weighing, perhaps he may be able to give some information whether he noticed the bunch rubbed before it was weighed.—JUSTICE.

WITH regard to this controversial matter, it appears to me to be of very easy solution. Surely the fruit stems of these celebrated bunches are preserved and can be submitted for examination. I suggest that they be forwarded to the Fruit Committee of the Royal Horticultural Society of London. That body is unquestionably unprejudiced and undoubtedly competent to determine, on that data, whether Mr. Curror or Mr. Dickson exhibited more than one bunch for the prize at Edinburgh.—A NORTHERN GARDENER.

ALL Grape-growers have an interest in knowing what constitutes a bunch of Grapes, and perhaps you will allow a pretty old Grape-grower, exhibitor, and frequent judge, to state that he has always been accustomed to regard a cluster with two distinct footstalks as two bunches, and never heard this definition questioned. It is a well-known fact that two bunches are often produced from the same eye. Sometimes they come with a fasciated stem, and sometimes the footstalks are quite distinct. Both examples are common in the Black Alicante; and though with us such bunches are always the largest—in fact generally twice as large as the others, we never yet thought of exhibiting such as a single bunch.

Now, putting aside personalities, Mr. Dickson's charges (page 323) on this head are distinct enough, and if false they are easily refuted. The question can be put in a nutshell: Had the Eskbank bunch of Grapes two footstalks, and were the Judges aware of it? If they were, then they have set the usual rule aside, rather unwarrantably it would appear; and if they failed to ascertain the fact, after what has been said on the subject of big bunches before, as regards their *bond fide* character, they made a grave omission.

If the facts are comestable let us have them. It is an awkward way of answering a straightforward question by referring to the immaculate character of the Judges. One is not disposed to doubt them, but let us have the facts; and while on this subject it is not too much, I think, to ask Mr. Dickson for the names of the gentlemen who are able to corroborate his statement. It would strengthen his case, and do them no harm whatever.—GRAPE-GROWER.

#### STANHOPEA BASKET.

ALL Orchid-growers have experienced the inconvenience of the unendurable nature of the wooden and wicker baskets which are ordinarily used for the cultivation of their epiphytial plants. They need no longer experience that inconvenience, for Mr. Matthews, the Royal Potteries, Weston-super-Mare, the well-known manufacturer of flower-pots, has produced a basket at once neat, light, and imperishable, and which must supersede the usual wooden baskets for the cultivation of Stanhopeas and kindred plants. This basket needs only to be seen for its merits to be appreciated. It should find its way into all Orchid houses. The accompanying figure gives a true representation of this useful aid to the cultivation of Orchids.—J.

#### POND'S SEEDLING PLUM.

I EXHIBITED at Daventry Horticultural Show, September 7th, six Plums that weighed 1 lb. 7 ozs. The tree grows on a south wall. In 1873 I gathered my

Fig. 78.

Earthenware Stanhope Basket.

first ripe Plums, August 2nd, from Early Favourite, and my latest from Pond's Seedling. In 1874 I had fruit from these varieties from July 20th to October 10th, and this year from July 22nd to the present time. Pond's Seedling is an excellent late variety. The hives have been much more troublesome this year than the wasps in destroying fruit. Can any of your readers give me the name of the dark Plum that took the first prize at the Stamford Show?—O. E. BRACKENRIDGE, Manor House, Kilsby.

#### OLLA PODRIDA—A CONTINENTAL TOUR.—No. 5.

I LEFT off in my last at Baveno: from there we started to cross into Switzerland by the St. Gotthard Pass. And here let me give a word of warning to any who wish to take this Pass by diligence, which starts now from Biasco, not to trust to the truthfulness of Italian hotel-keepers. We wanted to secure three places in the coupe of the diligence, and wrote to the landlord of the principal hotel at Biasco, asking him to secure them for us. We received no answer; so, after three days, we telegraphed, and had as a reply that all the places in the coupe were taken, but that there would be, most probably, a supplementary diligence, in which case he would try and secure the coupe seats; but—and here was the gist of the whole matter—he could be certain to secure a return voiture at but little greater cost than the diligence. We started late in the evening, took the steamer to Locarno, and then went by train to Biasco, where the landlord met us, and again assured us that there were no coupe places to be had in the diligence, and wished us to make arrangements for a voiture with a person who entered the train at Bellinzona, and had immediately tried to make us hire his voiture, for which he wanted at first 200 francs. We refused point blank to have any dealings at all; and I rose up early in the morning, went down to the office of the diligence, and found that the whole story of the coupe places being taken was a fabrication, as no places had been booked at all. I consequently booked three places, and went back to the inn, when the landlord met me, and was very sorry no places could be had, and he could supply a return

voiture at a less price than that asked the night before. I answered, he need not distress himself, as I had the tickets for the diligence in my pocket.

Biasco is situated in a narrow valley at the head of the Lake Maggiore, the river Ticino running into the lake past it. At Biasco the valley branches, one road going to the St. Gothard Pass, the other leads to the Lukmanar Pass. The valley from Biasco to the Lago Maggiore, called Riviera, is very warm and sheltered, and abounds in vineyards. We were very unlucky in our day for crossing, the heat was intense; there had been no rain for a long time, and the roads were worked up into white dust from 3 to 4 inches thick, mixed with loose stones. The roads are mended with white granite containing a good deal of gneiss, and owing to the railway being in process of formation and their being at work at the tunnel between Airolo and Goschenen, there had been a more-than-usual amount of traffic along the roads, and they were much cut up; to add to our misery the wind was at our backs, and was sufficiently strong to blow the dust after us, so as from time to time completely to envelope us in clouds of dust, which prevented us even from seeing the horses in our own diligence in front of us. Three other carriages followed in our track, and at times we had the accumulated dust of all three added to our own; add to this that a midday June sun was pouring down upon us in a narrow valley, and your readers may judge that our experiences were by no means pleasant. I will not, however, dwell on the discomforts, though till then I had no idea how unpleasant dust could be. As in crossing by the great Mont Cenis tunnel, so here, too, as we gradually rose the valley of the Ticino the vegetation altered, and I was not sorry to be rid of the white Mulberries to get to the Chestnuts and Walnuts; then after Airolo both the Vines and Chestnuts, and also the Walnuts, ceased, and we reached the Firs and the Pines.

Between Bodio and Faudo the mountaineers were busy in securing their crops of hay, and it was rather strange to my eyes to see all the hay carried to the stacks on men's backs. Large cocks of hay were bound up with ropes and hoisted on to men's shoulders, where they were carried on a peculiar kind of shoulder-boards, with projecting arms below the shoulder-blades, the rope being grasped in front, and the bundle of hay held taut against the shoulders. This contrivance seemed to equalise the weight, and great bundles of hay were carried in this way where it would have been almost impossible for a cart to have worked.

After Airolo, where one end of the long St. Gothard tunnel begins, the scenery began rapidly to change. The St. Gothard tunnel will be about a mile longer than that through Mont Cenis; they are working it by means of water power from each end, but they do not expect to have it finished till the year 1881. Soon after crossing the opening of the tunnel at Airolo the road begins to make a rapid ascent up the Val Tremolo by means of zigzags. Here we passed through meadows filled with alpine plants, which were at that time in full flower, and nowhere did I see them in greater profusion. But here I may venture to remark that—though my own experience, perhaps, is limited—I cannot see that there are many more wild flowers to be found in these alpine regions than in our own lanes and hedgerows. Some, no doubt, as the *Primula farinosa*, *Primula auricula*, *Gentian*, &c., are very pretty, but on the whole I was disappointed, and never found them anywhere in the same abundance as I had been led to expect. After the alpine meadows our road laid through some Pine woods, where, in walking from one zigzag to another, we came upon a very beautiful fall of the river Tessin or Ticino. Soon after this the road continues to rise very rapidly by means of zigzags, in one place there being no less than twenty-eight in succession, and we were very soon above the limit of the Pine woods to vegetation of the most barren description, chiefly Moss and Lichen, though here and there plants are to be found of the dwarf *Dianthus*, &c. The top of the Col de St. Gothard is 6936 feet above the sea (for which information I am indebted to Murray). We did not reach there till after eight o'clock, and found the inn and opposite hospice at the top full to overcrowding of Italian workmen, who are quarrying the loose boulders of granite for the sake of the masonry and approaches to the tunnel. They were all eating a sort of strabont soup of macaroni out of wooden bowls. I do not think I ever saw humanity packed much closer together feeding.

We only stopped at the top to change horses, and then went down to Horpenthal. The descent in the dark was by no means pleasant, the drivers and horses, which are accustomed to the

work, swinging the diligence round figure-of-8 curves, with a descent of about 1 in 7, at the rate of eight or nine miles an hour. The diligence stays for the night at Andermat, but we stopped short at Horpenthal with the intention, if it were fine, the next day of paying a visit to the Rhone glacier at the Furea, but fates decreed it otherwise. The next day looked threatening, and we wisely gave up the idea, and at one o'clock, or before, it began to pour and continued the rest of the day. In the morning I climbed with a friend a short way up the side of one of the hills to look for alpine plants, and found some good beds of *Primula farinosa*, which seem to like the damper situation.

I had no idea before how hardy the common Alder was; it was here growing above the line of the Firs, and where the little ravines were still covered with snow the boughs, which had been completely weighed down and covered with snow, were beginning to start into leaf, while those growing on the tops of the ravines were nearly in full foliage. Can any of your readers tell me if there is any tree that will grow at a higher elevation than the Alder?

The next day we abandoned the diligence (not being sorry after our experience to be rid of that means of locomotion), and took a carriage for Tels Platte on the Lake of Lucerne. The roads after the rain were a pleasant change from our previous day; and what most struck me in our day's travel was the great luxuriance of the Ferns. The first we saw, or rather which much attracted our attention, were some beautiful plants of the Parsley Fern growing in the walls which support the road in the zigzags immediately after passing the Devil's Bridge, where the road crosses over the foaming torrent of the Reuss. From that point all the way down to Arsteg we saw Ferns in abundance, chiefly *Pteris aquilina*, *Adiantum*, *Athyrium filix-femina*, *Lastrea*, &c.

I will now digress to remark that those persons who think it right to make artificial rockwork look like natural stratification are mistaken. What I have so often observed before in moorland dales and narrow ravines up the sides of mountain streams I noticed here too on a larger scale—that the Ferns were never growing in the natural stratification, but in the *débris* of the fallen rocks, among loose stones, under huge boulders, or wherever the soil washed off the overhanging cliffs was covered with broken rocks. Nowhere—and I kept a good look-out here and afterwards among the hills and rocks on the sides of the Lake of Lucerne—did I see Ferns growing out of the strata where it had been exposed by the fracture of the rock. Why I am induced to make these remarks is because some persons—and among them Mr. Ingram of Belvoir, whose opinion I do not like to gainsay—find fault with any rockwork put together for the sake of growing Ferns and alpine plants unless every stone is laid in its natural bed. Now, I have found as an invariable rule that where I have seen Ferns growing best has been under cliffs and in ravines, or by the side of mountain streams where no single stone is lying and in its natural bed—that is, in the strata in which it was deposited. About Bayeno and again about Bellagio the finest specimens of Ferns were growing in the walls by the side of the vineyards and roads. And after passing Goschenen on the St. Gothard route to Wasen, where the road passes through Pine forests, the Ferns are all growing most luxuriantly in the *débris* of the rocks which fall from the stupendous cliffs that tower many thousands of feet overhead. It is a mistake, I maintain, to try in rockwork to imitate cliffs and stratification. This I shall allude to again when I conclude these notes with a few remarks on Battersea Park, which I went to see on my return, in order to compare our English and foreign gardening; and my apology is due *en passant* to Mr. Rogers who kindly escorted me round Battersea Park, for being so long before I get to the end of what I am afraid your readers will think a somewhat prosy paper.

What I maintain is, the object of rockwork and rockeries is to grow Ferns and alpine plants in an ornamental and picturesque way, and in a way which is best suited to the habits of each kind of plant; and this can only be done, not by any attempt to imitate nature or by making concrete and stucco stratified rocks, but by using stones and soil, and taking advantage of sun and shade, north aspect and south, dry places and wet, &c., according to the kind of plants you wish to grow. If when you take up a stone to put it on to the rockwork are you to think which is its bed?—did it lie on this side or that? You simply make yourself a slave to an idea. Where Ferns and alpine plants grow to the greatest perfection Nature has performed wild freaks and will do so again, and in many a

place no one stone will be found in its original bed. This, however, is a digression, but a digression which I have been induced to make, because all that I saw in Italy and Switzerland so certainly confirmed what I have previously noticed in the woods and dale valleys in Yorkshire, where Ferns grow with great luxuriance and beauty, that nowhere do they succeed so well as in the loose stones and *débris* washed down the face of the cliffs or in the beds left by mountain torrents. I do not mean to say I never saw a Fern growing out of the exposed strata of rocks, but it is an exceeding rare thing to see them do well, and none hardly but the *Ruta muraria* or the *Oterach officinale*, or occasionally the *Blechnum boreale*; but as a rule Ferns rejoice in much more depth of soil, and shade, and moisture than stratified rocks will give them.

On the Switzerland side of the St. Gothard Pass we did not again meet with the same luxuriant vegetation as in the valleys on the Italian side. The valley of the Reuss as it nears the Lake of Lucerne is, however, very fertile; and after passing Amsteg the roads are much improved by the use of the mountain limestone for roads instead of the white granite. The Reuss is full of the detritus of granite and gneiss washed out of the mountains by glacier action, and the whole of the Lake of Lucerne, especially at the north end, is coloured by it. At Lucerne the waters of the lake leave it a deep pure green, and, till the Reuss joins the Rhine, the water of the river is very beautiful to look at. Here I will conclude for the present, and will finish in two more papers with a few remarks on Paris and Battersea Park.—C. P. P.

### OUR BORDER FLOWERS—WALLFLOWERS.

This is an extensive family of plants met with in many parts of the world and under various circumstances. We, too, in our "own loved land" have a grand representative of this cherished family in *Cheiranthus fruticulosus*, so prized among our rural population. Few of them would like to be left without their favourite, for a garden is not complete without Wallflowers. They appear to cling to the old home with a lifelike tenacity, and well have they been termed the emblem of fidelity. They attach themselves to the desolate, and conceal the crumbling records of feudal times; they occupy the chinks of the mouldering edifice, and weave garlands of beauty on the ancient monument.

"For this obedient breeze bear  
Her light seeds round yon turret's mould,  
And undispersed by tempests there  
They rise in vegetable gold."

Wallflowers are at home everywhere. They are of shrubby habit, sometimes lasting for years. When once established they take care of themselves. Others there are that require more attention; these are the beautiful double varieties that are not met with so often as they ought to be, nor nearly so often as they might be. In old-fashioned times and in old-fashioned places you might meet with three or four varieties of double Wallflowers, but now you look for them in vain. I would ask, What flower is more esteemed, and especially for fragrance? The old double Wallflowers are easily increased by cuttings made of half-ripe shoots which may be struck in heat, or by shoots taken off with a heel in autumn and inserted in light sandy soil under a handglass, also by layering during the summer.

For indoor decoration no plants are more desirable. With care they may be grown to a large size in pots; by stopping and potting-on they may be made to approach a small bush in form; and when in bloom in late winter and early spring what can be more charming than these fragrant Wallflowers? They succeed well at the foot of a wall or by the dwelling house side in dry sheltered situations. One of the best of the double varieties is *Cheiranthus purpureus* and its compeer the variegated variety, and when grown in masses the air becomes loaded with their perfume. As they have been, so must they remain, favourites with all lovers of beautiful-scented flowers.

The German Wallflowers are a splendid race of plants: they may not emit such a perfume as our own, neither do they prove so hardy in our changeable climate, yet they do us good service for spring garden and border decoration. Then we have *Cheiranthus alpinus*, a real gem, perfectly hardy, and readily increased by cuttings in autumn in a cold pit or under hand-lights, or by division in early spring. It is a capital rock plant. *C. Marshallii* is a telling plant in the spring garden, and is worthy of extensive cultivation; *C. ochroleucus* is much like *alpinus*, and is sometimes substituted for it. The plants should

be frequently renewed or they become unsightly, and old plants often drop off altogether after winter. All are beautiful, lasting a long time in bloom.

There are many other kinds equally attractive which ought to be more sought after, but those I have named are among the best of the race and should be in all collections.—*VERITAS*.

### BEEES AND FRUIT.

I REG to add my testimony to the destructive habits of our honey-producing friends. I thought I was the only sufferer by their fruit-eating propensities, and would bear the inconvenience in silence in the hope that they would of themselves leave off troubling me. I thought, too, that I might be accused of presumption had I made my trouble known. I will now state that they have not forgotten for the last four years to visit my British Queen Strawberries, and defy all my powers to prevent them in their attacks, and the worst of it is the bees are not our own, but come from a distance. The destruction they make is incredible. Apriots have also come in for their share of attack as well, and the only means to prevent their ravages I find is to gather the Apriots a little under-ripe and place them in a warm room where the bees cannot obtain ingress. My Aston Red or Warrington Gooseberries, netted or matted, they are determined to have and devour. I have not seen them attack other kinds of fruit.—*OBSEVER*.

I THINK that bees are of great and inestimable value in setting the fruit of Gooseberry, Plum, Apriot, Peach, Apple, Pear, and other fruit trees, and that it is but seldom they injure fruit. My experience extends over fifty years, and I have witnessed two cases only of bees injuring fruit. The first time was in September or October of 1843. The weather being warm, and the flowers being over, the bees did attack and destroy many luscious fruits of Coe's Golden Drop Plums that were hanging near to them. The other case happened in 1868, when the herbage was burned up by a long and severe drought. There were no honey flowers, and the weather was uncommonly hot. The bees then resorted to Raspberries, sucked the juice out of them, and rendered them comparatively worthless. In neither case were the bees prompted by hunger, having plenty of honey in their hives at the time mentioned. Our bees are surrounded by Raspberries, but they have never touched one since.—*A. PETTIGREW*.

### SALVIA GESNERÆFLORA.

EVERY October for I cannot remember how many years past I have had the pleasure of potting up from the open ground immense pyramids of this fine *Salvia*. My lot has fallen in a place where not only a full display of flowering plants are required, but where scarlet is expected to be the prevailing colour. Now, it is not an easy matter to set a conservatory ablaze with scarlet during the winter and early spring months, but the plants which above all others are capable of producing it are *Salvias*. Scarlet and white are the most effective colours for winter. Both by daylight or gaslight they are alike striking, and if the flowers can be had in elegant sprays they are doubly useful for many purposes of decoration and in giving relief to the formal masses of *Camellias*, *Azaleas*, &c. For affording floriferous sprays of these colours my staple plants have long been *Deutzias* and *Salvias*.

*Salvia fulgens* is now in full beauty, and will continue until December. *S. splendens* will continue until February, and by that time the handsome pillars of *S. gesneræflora* will be in their zenith of beauty, lasting until April. But while all of the trio are useful, the one last named is the greatest and the best.

Very commonly are these plants grown in pots throughout the summer, but by that mode of culture it is almost impossible to bring out their full beauty. By an occasional want of water or an insufficient amount of food the foliage loses its rich green tint, and the plants are deprived of half their attractions. By planting-out in deep rich ground in May and affording occasional supplies of liquid manure, every leaf is preserved of a full deep green, and the spikes are produced of twice the size over those from plants which have been grown in pots.

By striking the cuttings in March, growing carefully on until May, shifting in larger pots as required, and subsequently planting-out, I have had no difficulty in growing plants 7 feet in height and 3 feet through near the ground, and tapering—as they will do without any pinching—to a point. Such plants

from February to April have few equals for conservatory and corridor decoration, and their out sprays are ever in request. If this simple mode of culture was generally adopted this fine plant would be seen everywhere where large plants of bright

flowers can be grown, but unfortunately it is rarely met with, and then only in a half-starved state.

Many gardeners do not know the plant, and not a few confound it with *S. fulgens*. It is, however, altogether more

Fig. 74.—*SALVIA GESNERIFLORA*.

robust than the last-named species, having larger cordate-ovate leaves, with an acuminate point, *a*; the leaves of *S. fulgens* being much narrower, elongate-ovate, *b*. The flowers grow in whorled panicles of a brilliant light scarlet colour, and are much larger than those of *S. fulgens*. *Salvia gesneriflora* was introduced from Central America in 1840.

This brief record of practice is the best reply I can give to

the correspondents who are seeking information on this exceedingly useful and easily cultivated plant.—EX-HIBITOR.

#### STANTHOPEA MARTIANA.

STANTHOPEAS are of very easy culture. Many of the species have singularly beautiful and quaint flowers, but they last only

a very few days in perfection, and to this cause more than to any difficulty attending their culture must be traced their decadence in popular favour. Basket culture suits their requirements better than any other system, and the baskets

need not be very deep. On the bottom place a layer of live sphagnum, and plant the Orchid in a compost of turfy peat, sphagnum, and potsherds. Ordinary stove culture answers well for all the species. The minimum winter temperature

Fig.

Fig. 75.—*STANHOPEA MARTIANA*.

should be 55°, but less or more than this will do no harm, although it is better it should occasionally fall to 50° than rise to 60° or 65°. A high winter temperature is very injurious to most Orchids, starting them into growth prematurely, which, if a high temperature is continued, impairs the constitution of the plants. It is seldom, however, that this happens with *Stanhopeas*, for the genus is not liable to start prematurely into growth.

When the plants are in growth the house ought to be warm, and a moist temperature should be maintained. Keep the plants moist at the roots, and syringe overhead daily should

red spider appear on the leaves. This and thrips are very troublesome, and the plants will not thrive if they are not kept clean. Scale is also sometimes found on the plants, but this is easily removed. It is necessary that the growth be made in a shady position. The basket may at this time be suspended under some of the climbing plants, and which are free from insect pests. For the purpose of shade no plant can be compared to *Clerodendron Thomsoni*, as the leaves of this plant are obnoxious to all insect pests, and afford ample shade. After growth is made the basket must be removed from the shady position to a more open one, and after the

pseudo-bulbs are ripened and the plant is at rest no more water ought to be given than just sufficient to keep the bulbs from shrivelling.

In "Paxton's Botanical Dictionary" instructions are given to pot Stanhopeas. Small bulbs to be raised but slightly above the rim of the pot, and large plants to be placed on a cone of peat a foot or 15 inches high. Such cultural instructions are at least half a century behind the present age, and ought not to have been retained in an edition of the work published in 1868. If the plants are but slightly raised above the rim the result will be such as happened to a gardener in the north. He ordered a collection of Orchids, and among them a Stanhopea was sent. The gardener potted his Stanhopea as directed in "Paxton," and it grew well but never flowered. A complaint was made to the dealer, and he went over to see this healthy Orchid that refused to flower. The acute nurseryman turned the plant out of the pot, and it was found to be beautifully in flower, but its exquisite beauty and powerful fragrance were lost amongst the ample drainage at the bottom of the pot.

Neat baskets of teak or pottery (not wire), such as the one figured on page 339, are best adapted for Stanhopeas; and with very little attention the plants will produce a profusion of flowers annually. But three things must be borne in mind: First, cleanliness; second, a season of growth; and third, a season of rest. *S. Martiana* is a native of Mexico, and produces its white or straw-coloured flowers during the autumn months. By growing plants of this species—*S. Bucephalus*, *S. insignis*, *S. oculata*, and *S. tigrina*—flowers may be had from June to November.—J. DOUGLAS.

### HARDY FRUITS.

MR. TAYLOR admonishes young gardeners to look themselves up a little in the cultivation of hardy fruits; many others of us may take the hint, and profit withal. The hardy fruit department is one of the most important points of our profession. Orchard houses under many circumstances are not what fancy painted them, and to many an industrious gardener they have been a source of grief and disappointment. I have known cases where men have felt continual failures so keenly that they were disposed to give up in despair, while to others they have proved a pleasure and a success as well as a source of profit.

I wish the time had come when not only gardeners but everyone who has a rod of land as a garden would devote some portion of their time to the cultivation of hardy fruits. There is nothing more beautiful to look upon than fruit trees in bloom, and in autumn when laden with fruit what can be more useful and profitable? I am inclined to think that pyramids are the most suitable form of trees, for when once put in form they are easily managed. Fruits of good quality always meet with a ready sale, and ought to be obtainable by all.—P. P.

### A TRIP TO LONDON.—No. 3.

#### BATTERSEA PARK.

THERE is no approach to Battersea Park that is so pleasant as by the river, and country visitors who are desirous of seeing something of other London sights as well as the public gardens will do well to go by steamboat to the park pier from any of the numerous piers above London Bridge. The embankments, the bridges, and several fine buildings are all seen to greatest advantage from the bosom of old Father Thames. This route is always preferable even in a fog to the noisy streets or the horrid "underground." A quiet stroll at Battersea affords many useful lessons as well as much enjoyment to a gardener, more perhaps than can be had in any other place so close to the metropolis. The early morning is the best time for a visit, the place being so much crowded during the evening that one's chief pleasure then consists in watching the enjoyment of others; but in the comparative quiet of the morning there is nothing to call the attention from the plants or to prevent a careful study of their various combinations.

Now for a few of the lessons. Note first the striking and graceful effect of *Ailanthus* and *Sumach*, with a front belt of *Cannas*. Here beauty is evidently imparted by the contrast of three kinds of foliage, all elegant and yet dissimilar. It was a happy idea to place the *Ailanthus* behind the *Cannas*, not only because of its tall growth, but from its spreading habit, so different to the formal erect growth of the *Cannas*. The group is all the more valuable because it is hardy, and may

fairly be expected to become more striking and effective year by year. At another point—a corner—we find a mass of common *Laurel* in splendid health with very large foliage of a deeper shade of green than I had seen it wear before, forming a capital background to some *Palms* and *Musas* associated with *Yuccas*. This was a fine group, and graceful from the absence of crowding, each plant standing sufficiently apart from the others to retain its individuality, and with the foliage of all charmingly intermingled. Another group totally different to this, but exceedingly chaste and elegant in its effect, consisted simply of *Pampas Grass* and *Sealortia elegans*; all the more striking from its position—an alcove formed by the shrubs. Then we come upon another fine arrangement of white *Abutilon* mixed with tall plants of *Fuchsia Sunray*, *Ficus elastica*, the yellow variegated *Abutilon Thompsoni*, and *Acacia lophantha*—a very beautiful group deserving especial notice, and not difficult to introduce into any garden.

Other combinations equally ornamental are seen at every turn, and it would require several papers to describe them fully; these I cannot contribute, but a few other groups shall have a passing notice. The *Polymnias* and *Wigandias* were of more than usual excellence, the huge foliage of both being abundant and very large. The plants were in quincunx order about 4 feet apart in the rows, and 2 feet between the rows; this distance affording ample space for the full beauty of the foliage to be seen, and yet showing no unpleasant looseness about the arrangement. The surface of the bed was carpeted with dwarf ornamental-foliage plants. A number of luxuriant *Wigandias* springing out of a dense wild growth of *Lantana* with pretty pink flowers was very good. Some New Zealand *Flax* mingled with green *Ivy* and variegated *Vines* gave a pleasing relief to a flat expanse beneath a tree. A flourishing little *Araucaria excelsa* about 2 feet high in a circle of about 6 feet in diameter was so beautiful that I could not but regret finding the bed carpeted with yellow foliage instead of a delicate shade of pink, crimson, or blue, either of which would have afforded a lovely contrast to the pale green tint of the spreading branches of the *Araucaria*.

Some of the carpet bedding was excellent, with well-coloured *Alternantheras*, and highly finished in every respect; in other examples the *Alternantheras* were not so bright. A carpet of *Cerastium arvense*, as dense in growth as *C. tomentosum*, and with bright green foliage, was most effective, with the orange red *Alternanthera paronychioides*, *Golden Pyrethrum*, and the carmine *Alternanthera amsona*. This green-leaved *Cerastium* is a great acquisition, and promises to supersede *Tagetes signata pumila* for carpet bedding. *Sedum acre elegans*, a pretty plant with yellow and green variegation, made a capital edging to this bed.

Two large circles had a novel and very beautiful arrangement, consisting of an interior band or chain of twelve small circles, each with a single specimen *Agave* in the centre upon a carpet of *Sedum acre elegans*, enclosed with a band of mixed dwarf succulents, with outer rings of green *Cerastium*, *Golden Pyrethrum*, and crimson *Alternanthera*. The centre of each bed inside this chain of circles had a carpet of *Alternanthera magnifica*, and outside the chain there was blue *Lobelia* with enclosing lines of *Leucophyton Brownii* and *Sempervivums*. The best of the specimen *Agaves* were *A. filifera nana*, a compact dwarf form of a deep green colour, with white longitudinal markings, black-spined tips, and numerous white thread-like filaments recurving from the edges. *A. americana variegata*; *A. verrucosa*, with very broad, deep green, spinous leaves; *A. alternata*, pale green with yellow stripes; and *A. filifera* with broad chocolate spinous leaves mottled with long green blotches.

A host of other subjects claim notice—alpine plants, Fern glades, shady banks not only clothed in green, but really as ornamental as a flower bed, with various succulent plants, Ferns, *Ivy*, *Ajuga*, *Vines*, and *Antennaria*; rocks clothed and fringed with *Cotoneaster microphylla*, *Bramble*, and *Jasmine*, as well as with succulent plants; water edged with *Sedges*, *Ferns*, and *Rushes*, &c. These passing notes will serve, I hope, to show that Battersea grows in beauty and interest in the hands of Mr. Rogers. I have been there many times, and have always come away with a feeling of time improved and knowledge gained, and never more so than on the present occasion.—EDWARD LUCKHURST.

DESTROYING MEALY BUG.—Carbolic acid judiciously mixed and applied to ripe Grapes will effectually disperse mealy bug, but the Grapes must be ripe, and then no injury accrues to

the fruit if well syringed with pure water; but the green berry is completely killed by it.—W. VINCENT.

## PLANTS FOR CUT FLOWERS AND SPRAYS.

No. 4.

**ALSTROEMERIAS.**—These have curiously-formed flowers with delicately-spotted or marbled petals, and being borne upon soft stems they are very enduring in a cut state. They commence blooming in July and continue until September. An open situation is the most suitable, and free from shade. The plants delight in moisture, but yet the soil must be well drained. A soil composed of sandy loam and peat will grow this genus to perfection. Plant the roots from October to November, or early in spring, 9 inches deep, surrounding them with sand, and all they will require after this for a generation is a mulching in autumn of vegetable soil or leaves nearly rotten. *A. aurantiaca* aurea, orange, with carmine spots; *A. brasiliensis*, red, tipped with green; *A. chilensis* varies in colour from red to white; *A. peltata*, crimson and purple spots; *A. Hookeri*, yellow, with red streaks, are a few of the best varieties. *A. pelegrina* alba, white, and *A. pelegrina* rosea, pink, and delicate-striped, are all that need be grown in pots, and they may succeed in front of a south wall if protected. Peat and loam with a fourth of sand will grow them well. They require copious supplies of water in the growing season.

**LILIUMS.**—The powerful odour of some kinds is so unendurable in a cut state in rooms, that I shall not include in this list the splendid *L. auratum* and the stately *L. giganteum*. Delightful as may be their perfume diffused through a conservatory or in halls, it is quite unbearable in the dining, drawing room, or boudoir. I do not wish to discourage the extended culture of the "King of the Lilies," but advise it to be grown in any quantity in beds or in pots, but as cut flowers their odour is not agreeable, and very unlike that of the beautiful *L. speciosum* or *lancifolium* and its many varieties, which from their delicate fragrance, purity of colour, beautiful shading and spotting, with the fine recurve of the petals, at once claim our attention and admiration. The stamens carrying the yellow or brown pollen add immensely to the beauty of the flower; but before cutting them the pollen-bearing parts should be removed by taking them between the finger and thumb, or the pollen, by moving the flower about, will come into contact with other blooms and spoil them.

The *White Lily* (*Lilium candidum*) has large snow-white flowers, and few plants are more truly beautiful or ornamental in garden borders during June. Its odour is powerful, but the blooms used sparingly are admissible in rooms. The double variety is more enduring in a cut state than the single variety.

*L. longiflorum*, with its large pure white trumpet-shaped flowers, is very fine and flowers early, but its variety, *L. longiflorum eximium*, has larger and finer flowers, and the plant is also of larger growth. The *L. longiflorum*, given greenhouse treatment, will flower in May, and as they have foliage in winter they should be duly supplied with water, and have a light and airy position near the glass. In the open ground they do best in rather sheltered situations, as mixed with *Rhododendrons*, in which beds they succeed admirably, having a mulching of partially decayed leaves in winter.

For associating with the white *Liliums* a fine effect is produced by the fiery scarlet of the Martagon or Turn-cap (*L. chalcedonicum*), which has the flowers recurved; whilst the *White Martagon* (*L. Martagon album*) is so choice as to tell well intermixed with scarlet zonal *Pelargoniums*. The double *White Martagon* (*L. Martagon album flore-pleno*) is very fine. The *Scarlet Pompon* (*L. pomponium*) flowers early in May and June, and is sweet-scented; the flowers are pendulous. The *Colchicum Lily* (*L. monadelphum Scovitzianum*) has fine recurved flowers, having black spots on a citron ground. *L. testaceum* is a nankew yellow, and has a fine scent. Fiery are the orange *Lilies*, formerly *L. aurantiacum*, but now *L. croceum*, and still brighter is the variety *L. croceum fulgidum*. I must include also *L. Humboldti*, golden yellow, spotted with crimson, and *L. Leichtlini*, yellow, spotted thickly with crimson. Of the fine *L. Browni* or *japonicum*, with its white large flowers tinted externally with brownish purple, I must also make note, for it is one of the finest of the trumpet-shaped class, and does well in a peat bed.

We now come to the *Tiger Lily* (*L. tigrinum*), which has much-recurved, splendid orange-scarlet flowers, spotted with

black or very deep crimson brown. *L. tigrinum Fortunei* is more floriferous, and the double variety (*L. tigrinum Fortunei flore-pleno*), orange scarlet, and very double; and the very fine *L. tigrinum splendens*, which is much the finest of the *Tiger Lilies* must not be omitted. These associated with the varieties of *L. speciosum* are truly magnificent, and do well in pots, but flower earlier than *L. speciosum*. *L. tigrinum* grown under glass will be in flower about the same time as *L. auratum*, and for filling a vase if we have *L. tigrinum* var. around the margin, and *L. auratum* blooms in the centre, interspersed with sprays of *Bambusa gracilis* and *B. Fortunei variegata*, the effect is superb. *L. speciosum* in variety is, for cut flowers, the finest of all *Liliums*, whether we consider its beautiful form, purity of colour, distinct marking, or delicate fragrance; and by growing under glass, as also in the open ground, its exquisite flowers may be had from July to September inclusive.

Most, or nearly all, *Liliums* may be grown in pots, but some do not do well, as the Martagon group, and all flower grandly outdoors. Beyond the longiflorum, speciosum, and tigrinum vars., with *L. auratum*, there is no need to grow in pots, as the *Lilium* season is surely sufficiently prolonged—viz., from June to October.

*Liliums* should be planted outdoors in October, though planting may be performed up to March, the ground being well and deeply dug and enriched with leaf soil and old cow dung. Good loamy soil, if it has a cool bottom but freed of stagnant water, and containing decayed or decaying matter as peat or vegetable refuse, will grow these plants to perfection, and they will not require attention for many years beyond a dressing of manure or rich compost every autumn, which will protect the bulbs and enrich the soil. Plant 4 to 6 inches deep; and if there are beds of low shrubs with suitable openings for planting, three or more bulbs planted in such spaces twice their diameter apart, will, with the flowers towering above the shrubs, have a grand effect.

In pots it is well to allow a distance of half the diameter of the bulbs from the sides of the pot, and a full diameter between the bulbs. The pots should have, when the bulbs are inserted, space left for a top-dressing of about 2 inches thickness, as from the base of the flower-stem the roots proceed which support the flowers; this top-dressing should be given when the stems are about 6 inches high. The bulbs should be covered about an inch deep. They may be placed on and surrounded by silver sand. The pots must be well drained, and the compost be equal parts of turfy loam, leaf soil, and sandy peat, and half a part old cow dung, and a like proportion of silver or sharp sand. The soil being rather moist when used, and the pots placed in a cold pit or greenhouse away from the drying influence of the heating apparatus, will not require water, or very little, until growth takes place, but the soil must not become dust-dry, that being prevented by watering around the inside of the pot, and not pouring it upon the crown of the bulbs. As growth advances water more freely, and when the flower-buds appear weak liquid manure given twice a-week will increase the size of the blooms. If required to flower early the pots should be introduced to a vinery or other house early in January, and at intervals of a month up to April. The first will flower in May or early in June, and a succession will be kept up until those in a cool greenhouse come in early in August.—G. ABBEY.

## NOTES ON THE BROWN-TAIL MOTH

(*LIPARIS CHRYSORRHŒUS*).

WHERE the Brown-tail occurs it is found in profusion nearly invariably from its habit of colonising, so to speak. And therein, as it seems, is one of the most notable distinctions between it and the closely allied Gold-tail. While the larva of the Brown-tail lives gregariously almost throughout its life (for as a rule they keep together until they spin their cocoons for pupation, though now and then a brood will scatter after the last change of skin), that of the Gold-tail (*L. auriflua*) is solitary in habit, or well-nigh so. As the eggs are laid in patches the young larvae keep together a little at first, but they scatter off long before the winter sets in; and when the time for hibernation arrives each spins his lonely habitation, and, hermit-like, abides until the spring calls forth fresh leaves on the Hawthorn. Two species, therefore, so much resembling each other in the imago state as to be chiefly known apart by the colour of the anal tuft, golden in one species, golden brown in the other, are thus notably distinguished by the habits of the larva. In markings the larva of the two also differ more

than do the two imagos. To me, however, the point of most interest is, how far the assertions of early writers on entomology—the illustrious Kirby, for instance—are to be relied upon as to the injurious effect the species has occasionally exerted on the trees of our orchards, and a lengthy memoir of this moth was compiled by Curtis, the species having the traditional repute also of having occasioned as much alarm in our country at one period as the locust frequently does in warmer climes. The well-known Editor of the "Entomologist," whose acquaintance with insects, derived from Nature herself, is so extensive, agrees with my view that there is much exaggeration if not actual misrepresentation in the statements about the ravages of the Brown-tail, which have been so freely copied from book to book. Certain it is that we have no recent chronicles of harm done by the species, though in France the larva is reported to do injury in some seasons to Apple and Pear trees. What has added to the difficulty of obtaining a correct history of the species is the fact that the allied species has often been mistaken for it, and the confusion renders it impossible to tell sometimes which the writer means. Bennie, a pretty careful observer generally, was evidently under the impression that both species formed winter nests. A clerical naturalist of our day, who in the extent of his writings has few to equal him, omits the Brown-tail from his work on the "Friends and Foes" of the gardener, whether by intention or accident I cannot say.

In the locality where I have watched the species repeatedly—viz., in the vicinity of Milton-next-Gravesend, the nests occur along the Hawthorn hedges, and the insects do not seem averse to a somewhat exposed position. In isolated places a few straggling parties may be found; but the bulk of the Brown-tails have centred themselves along hedges lying in close proximity to each other. They were first observed by me in the autumn of 1873, soon after they had formed their winter nests, and in each season since there has been a gradual increase of numbers, so that what they may arrive at finally is doubtful. Possibly some reader may wrathfully exclaim, "You, a contributor to the *Journal of Horticulture*, ought to set to work and destroy them at once." I beg to differ. What reason have I for cutting off the lives of a number of insects on mere suspicion? In these hedges where the larvæ abound, besides Hawthorn various shrubs grow; the only one, however, they condescend to touch is the Blackthorn. Even Oak does not appear to please them. Willow does not grow in their range, though it has been reported to me that the larvæ have been taken upon that. There are large orchards and many scattered fruit trees in the district around Gravesend and Higham; hence if the Brown-tail was really a dangerous enemy, it is true much harm would ensue were the species to extend itself and proceed to attack trees.

The larvæ are unquestionably sluggish. In one spot particularly I noticed that where one strip of hedge had been defoliated by the hosts of larvæ some of them were dying on the twigs for want of food, yet by merely crawling across a moderately wide road they might have obtained an abundant and fresh supply. This to me tells decidedly against the supposition that the Brown-tail larva could ever be an important garden pest, since almost universally it holds good that those species which are most prejudicial to horticulture have a facility in transporting themselves from place to place; and nothing can be more simple than the operation which in any particular locality would soon largely reduce the number of, or even exterminate the larvæ of the species. It could be done, too, without putting the insects to any pain, supposing, that is, they are capable of that sensation. All that is necessary is to go amongst the bushes in the winter with a pair of shears, clip off the white nests of the larvæ, which are very conspicuous on the bare twigs, and then burn them. At this moment I could indicate, perhaps, as many as five hundred nests, which, at an average of a hundred larvæ to a nest, would represent fifty thousand individuals; but I am not prepared to advise such a "slaughter of the innocents." Though some folks may argue that there is a double reason why the Brown-tail larva should find no favour at our hands—for besides the known damage it does to the Hawthorn, the hairs of the species have a marked and specially unpleasant effect on the human skin. Of course there are those who feel them not, just as there are those who can defy the attacks of fleas, but with many persons these hairs produce painful swellings somewhat akin to nettle-rash; and you cannot have them once and be done with them, for they come up again and again if you meddle with the larvæ. I have authentic reports of persons who cannot ap-

proach without discomfort the hedges on which these are feeding; and though the urtication is produced at all times by the larvæ when they are in a state of activity, it is worse when parties of them are casting their skins or forming their cocoons, as the loose hairs float about in the atmosphere.

Lastly, I would say that it would be of much interest to myself, and doubtless others, if any horticulturists who have had under their own observation any case where this species attacked fruit trees (or Roses?) would communicate such details as they can give.—J. B. S. C.

## NOTES AND GLEANINGS.

We have received from Messrs. Rivers & Son of Sawbridge-worth a branch of the PLUM BONNET d'ÉVEQUE, which is so laden with fruit as to give it the appearance of a branch of Damsons. This is an excellent late Plum, and possesses a flavour which is unusual in Plums of this kind so late in the season. It appears to be an unusually great bearer. Accompanying this were some fine large fruit of Reine Claude de Bay, and handsome fruit of that delicious October Pear Beurré Hardy.

In the nursery of Messrs. Kelway & Son, Langport, Somerset, may now be seen growing an extraordinary crop of Mr. Kelway's new CUCUMBER CONQUEROR. Specimens of this variety were exhibited at the Royal Horticultural Society held at South Kensington September 1st. The seed was sown May 15th, and thirteen plants were planted-out June 2nd, each plant now bearing on an average (without the aid of artificial heat) thirty fruits, from 18 inches to 34 inches in length, and weighing from 2 to 4½ lbs. each. The house in which the above are growing is erected and glazed on Mr. Kelway's new principle, without wood or paint being exposed, thus doing away with the old and troublesome method of fixing the glass with putty.

At a Meeting of the HORTICULTURAL CLUB, held at the Club House, 8, Adelphi Terrace, on Wednesday last, the following gentlemen were admitted as members:—O. J. Bigley, Bridge Hall, Bury; F. G. Dougal, Clyderdale Bank, Glasgow; George T. Rollison, Tooting; Joseph Stevens, Grassmere, Byfleet, Surrey; Hugh Austin, Glasgow; and Edward J. Beale, Stonydeep House, Teddington. We may add that all the arrangements are now complete, and that the Club has every prospect of a successful career.

We are informed that in the counties of Cumberland, Westmorland, and north-west Lancashire GOOSEBERRIES, APPLES, PEARS, DAMSONS, AND PLUMS have all been equally good, and the trees have had to be supported to enable them to bring their fruit to perfection. The markets are so full that American fruit is very rarely seen now, where are great quantities used to be sold in ordinary years. Potatoes are also a splendid crop, and little affected by the disease; whilst Hazel Nuts, Acorns, Blackberries, Elderberries, Raspberries, Haws, and all wild fruits are in great abundance.

MESSRS. CARTER & Co., 237-8, High Holborn, have received a letter signed by the Executive Committee of the Cologne Exhibition, informing them that the Jurors have awarded them the silver medal for the GRASS SEEDS supplied for the creation of turf on the exhibition grounds, &c.

At the sale of ORCHIDS late the property of John Russell, Esq., Mayfield, Falkirk, by Mr. J. C. Stevens on the 1st inst., the following prices were realised:—*Cypripedium Lowii*, £21; *Oncidium splendens*, £31 10s.; *Saccolabium Russellianum*, £29 8s.; and *S. Holfordii*, £23 2s.; *Angraecum sesquipedale*, £25 4s.; *Aërides Fieldingi*, £31 1s.; *A. margaritaceum*, £26 5s.; and *A. Veitchii*, £36 5s.; *Cattleya Russelliana*, £44 2s.; *C. labiata Warnerii*, £30 9s.; and *C. Dowiana*, £27 10s.; *Coleogyne cinnamomea*, £23; and *Saccolabium guttatum*, £65 2s. There were 639 lots offered; the total proceeds of the sale being £2211 14s.

MESSRS. KEELING & HUNT have received a letter with reference to the FIRST SHIPMENT OF AMERICAN PEACHES to the London market, stating that "by this successful experiment the Allegetti Refrigerator Company of New York City have demonstrated that they can place the American Peach in the London market."

## NOTES ON VILLA AND SUBURBAN GARDENING.

BLANCHING ENDIVE.—As winter approaches this harder kind of salading is more useful than at any other time of the year.

In order to make it tender a regular process of blanching should be carried out. There are various ways of doing this, but nearly all are simple in application. The first, and perhaps one of the oldest methods, is that of tying-up the leaves about two-thirds the way up the plant, enclosing the heart in such a way that no light can reach it. This answers the purpose very well, but some attention is necessary only to tie-up sufficient to last for a certain length of time. By this mode of blanching, and if the tying is properly done, much of the wet will be thrown off by the leaves, and rotting of the plants will be averted.

The broad-leaved Batavian is a cabbaging sort, and is about the hardiest, and will endure exposure to wet after blanching without rotting for a considerable time, but not so the Dwarf Green-curbed and the Moss-curbed, which should be blanched in another way. Two boards placed lengthways over the rows and set-up ridgelike would keep the plants dry and blanch them; or, if only few are grown and pots can be spared of the right size, the plants can be gathered-up with the hand and the pots inverted over them, stopping the holes up at the bottom. This is probably the simplest and the best plan for the amateur to adopt.

In whatever way the plants are covered they must be perfectly dry at the time, which is generally in the afternoons of sunny days. As the season approaches towards the time for frost and snow the plants should be taken up and placed under the protection of a frame, and by plunging the roots in damp soil the plants will keep fresh a long time. In the absence of frames I have many times taken up the plants and plunged them thickly under a wall, and covered them over with boards, pots, or hand-glasses, and then covered the whole with straw or mats—in fact, almost anything that will keep them dry and free from frost. Where salads have to be supplied daily through the winter months, and Endive being one of the principal ingredients, any means whereby it can be preserved is to be sought after.

While on the subject of salads I should state that the Lettuce, being so tender and sweet, must be retained for the salad bowl as far into the winter as possible. It is my custom to sow a lot the last week in July or the first week in August on a dry border under a wall. The plants from this sowing are not transplanted, but merely thinned-out to proper distances, say from 8 inches to a foot apart. These are now turning-in well, but are not large. They will shortly have some glass or boards placed over them at night. Plants which are in the frames will have all the air possible in fine weather, and if any are left unprotected they will be used first. The best sorts are the black-seeded Bath Cos and Tom Thumb Cabbage Lettuce. The former sort should be chosen from a later sowing to stand over the winter.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

It is desirable to sow *early Peas* on a warm border about the end of this or the beginning of next month, and the gardener who would be successful with this, or indeed any other crop, must make previous preparation. It is a mistake to allow the ground to remain undug until the time that the seeds have to be sown, and then to either dig or trench it hurriedly, sowing the seeds immediately after. At no season of the year should this be done, and late in the autumn more care is necessary than at other time. In many places the time of the head gardener is much taken up with the forcing and decorative departments, and the young gardeners are seldom interested in kitchen-garden work. The general belief is that anybody can grow Cabbages and Turnips, the result being that the work is done in a careless manner and with but little previous forethought. Some of our ground has been trenched, but it is at present quite unfit either to receive seeds or plants, having turned up so wet. Now if the trenching had not been done until it was time to sow the seeds, there would have been no time for any further preparation. Owing to the rapid succession of crops it is not always possible to give everything the best chance; but when the soil turns up wet, as it is at present after so much rain, it ought if possible to lay a month, and the surface should be forked over lightly two or three times, taking the opportunity to do it when the surface is dry. Exposing the soil to the air in this way causes it to crumble down finely, and it is then in the very best condition to receive the seeds. We are now trenching a border for Peas, and a month hence will be early enough to sow them. A border facing south and sheltered on the north side by a wall is the best position for early Peas. The best sorts are Laxton's William I. and Alpha, the last-named is an early wrinkled Marrow.

The same attention is necessary for *Cauliflower* plants; these are planted in handglasses, but we likewise obtain some dry fine loam and place in the handlights, covering the surface to the depth of 2 inches or more. Our glasses are 22 inches square, and contain four plants, one at each corner; one or two extra are planted in each light, in case of any accident to any of the permanent plants during winter. The remaining plants are

pricked-out into portable boxes. The boxes can be moved to any position, and during severe frosts they are placed in glass frames. The thermometer has not yet fallen below 45° at night, but frosts may be expected at any time. Until sharp frosts set in late Cauliflowers are best in the ground, but towards the end of the month it may be necessary to remove some of them to an open shed or some such place. The plants are pulled up by the roots, and have a portion of the outer leaves removed, and they may be planted in some damp mould. It is better to store such plants in a vinery or Peach house from which the fruit has been removed, as light and air is of much benefit. We have occasionally pulled the plants up with the roots, and hung them by the heels in a shed, where they keep good for two or three weeks at this season. Lettuce has been planted-out in rows a foot apart and about the same distance between the plants. Hick's Hardy White Cos is our standard variety. All crops must be kept free from weeds, and on any drying day the Dutch hoe may be run through the ground, even if there are no weeds to be destroyed.

### ORCHARD HOUSE.

The trees have now been removed out of doors to be plunged in cocoa-nut fibre refuse. There is no better material than this for plunging pots in either out of doors or under glass, and the same material will last for many years. When it has decayed considerably worms get into it, but they are prevented from working into the pots by placing a handful of soot under each pot; this is obnoxious to them, and they will not go near it. The pots are now plunged up to the rim, and some fresh fibre refuse will be placed over the surface to prevent the frosts from penetrating to the roots. Many of the trees become mis-shapen and unhealthy in the course of years. All that are not worth retaining are destroyed as soon as the fruit is gathered, and a succession of plants kept up by purchasing "maiden" trees (that is, trees one year from the bud) from the nursery. The roots are trimmed back to allow of trees being potted in 9 or 10-inch pots. The trees are received in November, and are potted at once, the pots being plunged out of doors with the others; the potting material for these is the same as that used for the older trees. Nearly all the best new and old sorts of Peaches and Nectarines have been tried in our orchard house. Those most preferred are Peaches Early York, Royal George, Early Grosse Mignonne, Bellegarde, Barrington, Grosse Mignonne, and Dese Tardive. Of Nectarines—Lord Napier, Elruge, Violette Hâtive, Pine Apple, and Victoria. Three of the Nectarines have been raised by Mr. Rivers, and they are very distinct and splendid fruits.

### ORCHID HOUSES AND PLANT STOVE.

In the cool Orchid house we have in flower at present *Odontoglossum crispum* (Alexandree); its lovely flowers last in beauty for a very long time at this season. *Epidendrum vitellinum* has been in beauty for three months, as has also *Masdevallia Veitchii*, the most beautiful of the species except, perhaps, the more free-flowering *M. Harryana*. *Odontoglossum grande* is also in beauty, while *Oncidium tigrinum* and *Odontoglossum bictoniense* are throwing-up flower spikes. There are many beautiful *Odontoglossums* and other Orchids that will be in flower during the winter months. Many persons fond of Orchids, but who object to the steaming atmosphere of an East Indian temperature and the expense of its management, can now with some pleasure, and at much less expense, indulge their fancy for this fine class of plants. The temperature with little or no artificial heat ranges from 50° to a maximum of 65°. We do not dry any of them off entirely in winter, but no more water is given to many of the species except sufficient to keep the sphagnum alive on the surface of the potting material. *Masdevallias*, especially *M. Harryana*, continue to grow during the winter months, and, indeed, many of the different genera are more or less active. Those plants that are in growth must have sufficient water at the roots to perfect the pseudo-bulbs. In applying the water none should be allowed to fall upon the pseudo-bulbs or leaves at this season.

The *Cattleyas*, *Dendrobiums*, &c., that have completed their growth in the Brazilian house do not receive much water, and only sufficient is given to prevent the bulbs from shrinking. The minimum temperature is kept as near as possible to 55°. The same treatment is required in the East Indian house, water only being applied when the roots have become dry. *Phalenopsis* and *Oypipediums* require rather more water than most of the others, and a little difference of treatment is necessary when the growth has not been completed. Some few Ferns in the stove of small size had filled their pots with roots, and it has been necessary to repot them, doing it carefully, and not shifting into pots much larger than the plants were growing in previously. After this month nearly all plants require rest, as but little growth is made, and the soil is apt to become sour if it has not been thoroughly penetrated by the roots.

### FLOWER GARDEN.

The beds and borders still look gay with *Pelargoniums*, *Verbenas*, &c., but decayed trusses of flowers and withered leaves render them unsightly; these must be picked off frequently.

The grass edgings and lawn must also be kept neat and trim. In many gardens there is a tendency to relax the attention that has been bestowed incessantly during the summer months; this should not be, and until the frost kills the plants we must labour to preserve neatness.

Excepting a few Tricolor Pelargoniums that had been dug up and potted, a sufficient stock of all other plants were obtained from cuttings. If it is necessary to lift a quantity of Pelargoniums it ought to be done at once, to allow of the plants being established before the winter months. A very large proportion of the oldest leaves should be removed before potting, for if the leaves are left on they will decay and have to be removed in a few days, and by removing them before potting much after-labour will be avoided. Cuttings of shrubby Calceolarias have been put into boxes; these are placed in a frame against a north wall until roots are formed, when the boxes are removed to a more open place.

We have planted out the Pinks in beds, but it has required some ingenuity to have the ground dry enough for planting. The beds had frequently to be forked over, and some very dry mould from the surface of the Vine borders mixed with the soil was of much benefit. The plants are put out in beds at the distance of a foot apart each way. Cloves have also been taken from the parent plants where they were layered, and planted in the place where they will flower. Carnations and Picotees that were potted a few weeks ago are now rooting freely. The lights are entirely removed from the frames by day, and placed over the plants at night or to throw off heavy rains. Miss Joliffe, which is usually classed amongst the perpetual-flowering Carnations, is quite different in habit from the usual type of them. Plants that were propagated from cuttings early in the year are now in full flower. They are now out of doors, and have been in the same position all through the summer months. It would be well worth a trial to plant a bed of this variety from spring-struck cuttings. The plants would flower about the end of September or early in October, and would be quite a novel feature in the garden.—J. DOUGLAS.

### TRADE CATALOGUES RECEIVED.

Jonathan Booth, Pole Lane, Fallowfield, Manchester.—*Catalogue of Carnations, Picotees, Pinks, and other Florists' Flowers.*

Eug. Verdier Fils Atné, 72, Rue Dunois, Paris.—*List of New Roses.*

Andre Leroy, Près la Station du Chemin de Fer, Angers.—*Descriptive Catalogue of Fruit and Ornamental Trees.*

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

**ELECTION OF ROSES.**—The returning officer would feel obliged by all lists being sent in by the 20th October, as he hopes to have the portion pertaining to the newer varieties in the issue of the first week in November. His address is, Mr. Joseph Hinton, *Warminster*.

**ADDRESS (C. Z.).**—We cannot name a dealer. See advertisement in our columns last week.

**ROSE TREES MILDEWED—CLEMATISES (C. T.).**—The Roses, though your house may be in a low and shady situation, may suffer from mildew owing to want of water at the roots, especially as they are trained against the house where the soil is dry. Mildew is of two or three kinds. One is promoted by a check to the sap caused by want of water; another kind by damp, owing to stagnant air. The best Clematises are Jackmanni, Rubro-vioacea, lanuginosa, Miss Bateman, and Lady Lonsborough. There are none that bloom either more freely or so continuously as Jackmanni. Do not discard your Roses till you have tried liberal treatment with plenty of liquid manure.

**PEAS FOR EXHIBITION (One in a Fir).**—Commander-in-Chief, James's Profile, Dr. Hogg, Connoisseur, Omega, G. F. Wilson, Duke and Duchess of Edinburgh, and Best of All have been exhibited to great advantage at the principal shows this season. Mr. Turner's coming Pea Dr. Maclean is a grand variety.

**LARGE GREEN GOOSEBERRIES (Idem).**—General, Green London, Shiner, Thumper, Telegraph, and Stockwell.

**STRAWBERRIES IN AUTUMN (Miss D.).**—We are glad to hear of your success. It is common for plants which have been forced in the spring to bear an autumn crop after being planted out, but not usual for established plants to do so.

**FORCING LILY OF VALLEY (P. F. S.).**—Pot the clumps in two parts loam and one part leaf mould or old mouldy manure. Do not fill the pots too full of soil and nearly cover the crowns. Plunge them in cocoa-nut fibre, covering them slightly, and in January introduce them into a gentle heat. If they can be plunged in a bed of leaves, affording a gentle bottom heat, it will be advisable to do so. When in active growth place them in a light position near the glass. The time of flowering depends entirely on the time they are introduced into heat and the temperature which is kept up. The temperature which is given to Vines will be suitable for them, for the increase of heat which is needed as the Vines grow will be correct also for the Lilies. You cannot have anything better than cocoa-nut fibre as a plunging material for your Hyacinths.

**EARLY BEATRICE AND EARLY LOUISE FRANCHES (F. O. M.).**—The Early Beatrice is the earlier of the two, and the earliest of all Franches. The Early Louise is a little later, but is a larger and finer fruit.

**TENNANT REMOVING ROSE TREES (de Old Subscriber).**—A tenant having planted in the garden of which he is the tenant Rose trees of any kind, or any other tree, shrub, or plant, has no right when leaving to take them or any one of them away unless the landlord gives him permission.

**VINES UNHEALTHY (A Subscriber).**—Take off the surface soil from the border, just baring the roots, and replace with 4 inches of fresh soil, and if leaves and charcoal can be added all the better; over this place 6 inches of rich manure, and the rains will wash in its virtues. You have done right in thinning the wood, and if you now apply fire heat with air and a dry atmosphere it will ripen, and Grapes will follow in due course.

**VARIOUS REFUSES FOR MANURE (Rouven).**—The sulphate of lime is a useful manure for Clovers, and the spent tanner's bark as it slowly decomposed would afford some nutriment to the grass; but that decomposition is very slow. Tanner's bark kept in a heap until decayed is a good manure. Gas lime and sulphate of lime mixed with night soil as a disinfectant would be a good manure for all kitchen garden purposes. To Rose trees the quantity applied should be small.

**MAGGOTS AT THE ROOTS OF POT PLANTS (W. S.).**—The maggots are only due to the presence of decaying matter in the soil, and may be destroyed by soaking the plants, after stopping the holes of the pots with clay, with clear lime water, which may be made by pouring water to line in a tub at the rate of three gallons to a pound of fresh lime, and allowed to stand forty-eight hours, and then employ the clear lime water. The pots should be deluged with water for about three hours, and then have the drainage set free by removing the clay stopping.

**EVERGREEN AND OTHER SHRUBS FOR SMALL GARDEN (E. H.).**—*Aucuba japonica*, *Berberis Darwinii*, *B. aquifolia*, *Buxus arborescens* and var. *marginalis*, and *Handsworthianus*; common and Portugal *Leucalis*, *Ilex Hodgkissii*, and the Silver and Gold Variegated *Mollies*, *Cupressus Lawsoniana* and var. *striata*, *Juniperus hibernica*, *Taxus baccata pyramidalis*, *T. elegantissima*, *T. fastigiata*; *Thujaopsis borealis*, *Thuja plicata*, and *T. aurea*. The preceding are all evergreen, and to those add *Rhododendrons*. Deciduous trees are Double Scarlet, Double Pink, and Double White Thorns, and Scotch Laburnum (as standards for the outside), *Duchess cruenta* flower-pale, *Bilbes sanguineum* and its variety *album*, *Spines arlesolia*, *Syringa pemosa* and var. *alba*. Those will be ample, and all are very hardy.

**STORING FILBERTS (Felix).**—Remove them from the husks, and store away in earthenware jars or packed in dry sand, and place them in a cold and rather damp cellar. If you wish to retain them in the husks have them thoroughly dry and place in the jars packed in silver sand, also thoroughly dry, and place in a cool rather damp cellar. Walnuts may be kept in the same way, but "hulled" of course.

**FUNGUS RINGS ON GRASS (S. M.).**—The cause may be due to the dryness and peculiarity of soil, but the effect is the fungus growing in circles, and it may be destroyed by making holes about 8 inches deep, and giving a thorough soaking of lime water. Small holes will answer, thoroughly saturating the ground.

**TREES FOR BLEND (E. G. H.).**—Lombardy Poplar is of quick and close growth, and the best of all deciduous trees for the purpose you name. Sycamore is also quick-growing, and though good in summer is not nearly so good in winter as the Lombardy Poplar from its closer growth. The best evergreens are Corsican Pine, Scotch Fir, and Austrian Pine, but the most beautiful and equally effective are the American Arbor-Vitæ and Lawson's Cypress. These grow at a rate of about half that of the deciduous trees.

**DAHLIAS BROKEN BY WIND (A Beginner).**—It will not make any difference to the storing and growth of the shoots from the tubers in spring. Take them up at once and store away after drying in sand in a place safe from frost, but as cool otherwise as possible. The ground for Dahlias ought to be well trenched, very liberally manured, and thrown-up roughly for the winter during dry weather in November, throwing it level by forking-over the first dry weather after February. No manure will be required at planting time, but some rich soil should be placed around each plant, supplementing it by mulching and copious waterings.

**PLANTS FOR OUTDOOR HANGING BASKET (W. A. Grow).**—For a basket of the size you name we should have the different varieties of Ivy-leaved Geranium, as the white and pink-flowered, and the variegated Silver Gem with pink flowers, and *L'Elegante* variegated kind with white flowers. Put in a plant of the kinds named at the corner of the basket, and between each a plant of *Lysimachia nummularia*, and have in the centre a good plant of *Tropaeolum Ball of Fire*. The basket should be done-up early in April, using rich soil, and by growing on in a greenhouse, and hardening wall off, it will be in fine condition by the end of May for suspending outdoors. Water very liberally during the summer, and give liquid manure twice a week.

**DEFINITION OF PINK, CLOVE CARNATION, AND PICOTEE (Rose).**—The Pink differs from a Carnation in being of lesser growth in all its parts, and the flowers are "laced," or have a circular stripe near the edge of each petal, and have an edge of white both outside and inside, the ground colour being white. The Clove Carnation has the edges of the petals serrated, the colour, stripes, or flakes, or splashes running from the edge to the centre of the flowers; or the flowers are self-coloured, and all have the odour of Cloves. The Carnation has the marks on its petals from the centre to the edge, and through the edge in flakes or stripes of colour. The Picotee has its coloured marking only on the outer edge of its petals. The characteristics and properties of each may be learned from our "Florists' Flowers," free by post from our office for 5d.

**SAND AND SALAD OIL AS A FERTILISER (G. C.).**—It will make an excellent fertiliser.

**ROSE HOUSE (E. B.).**—Your house, we presume, from having to be fixed against a south wall, will be a lean-to; but we should have it, nevertheless, a half-span. The width, 21 feet inside measurement, will give you 8 feet for border all around the outside, 8 feet for each pathway, and a central bed of 9 feet. All the Roses to be planted-out, the walls to be built in the arched fashion, or pillars of a brick and half with 2-foot openings between, and arched over just below the ground level; this will permit of the coats passing from the inside to an outside border. The border to be 2 feet 6 inches deep, with 9 inches of drainage, and having drains not less than 2 feet apart with proper fall and outlet. Good sound rather strong turfy loam with a third of well-rotted manure and an eighth of half-inch bones would form a suitable compost for the border. The walls we should not take up higher than 2 feet

and have 8 feet of side lights, and all made to open; the roof should have an angle of 45°. Beneath every rafter, which ought not to be nearer than 4 feet, have four wires fixed 6 inches apart, and 15 inches from the glass, and in addition we should have arches over the pathway at the same distance apart as the rafters, and the back wall wired—the wires 6 inches apart, and not more than three-quarters of an inch from the wall. In the border all around plant dwarfs, alternating with low standards, or better all dwarfs, training them as pyramids. The central bed will hold three rows of plants—a central one of standards, and two of dwarfs trained as bushes or pyramids. It will be desirable to have the house heated with two rows of 4-inch pipes in an open flue in the pathway, with an iron grating as a covering. This will enable you to forward the plants, and to prevent injury from severe weather, but keeping the house cool and dry after September and up to the middle of January, giving plenty of air, for which you need to make provision at the upper part of the roof, having a light to open the whole length, and 2 feet 6 inches in width. The kinds we advise are, for the rafters, *Tea-scented*: Belle Lyonnaise, Catherine Marmet, Climbing Devonensis, Gloire de Dijon, Madame Cécile Barbot, Madame Hippolyte-Jamain, Madame Levet, Tour Bertrand, Helvetia, Annie Oliver, Cheshunt Hybrid, Marcellin Roda, and Perle de Lyon. *Noisette* for the same purpose: Marie Acery, Claire Carnot, Coquette de Blanches, Lamarque, Miss Gray, Ophir, and Solitaire. The back wall we should cover with *Marchal Niel*. For the arches or pillars: *Tale de Bourbon*, *Emotion*, *Gloire de Rosemère*, and *Hornea*. *Perpetuelle*: Alfred Colomb, Auguste Newmann, Baronne de Bonestettin, Baronne Louise Uxnull, Boule de Neige, Edward Morren, La France, Madame Liabaud, Charles Lafeyvre, Princess Beatrice, Souvenir de Julie Gonod, Thomas Mathew, and Suzanne Wood. *China*: Ducher, Cramoisi Supérieure, and Clara Sylvain. *Bourgs*, *Tea-scented*: Alba rosea, Duchesse of Edinburgh, Devonensis, Gogebault, Jeanne d'Or, Madame Bravy, Madame Jules Margottin, Marie Slaley, Nazaire, Odorata, Smith's Yellow, Safrano, Sombreuil, and Triomphe de Graillos Fils. *China*: Mrs. Bosanquet, Odine Forestier, Margarita, and Rêve d'Or. *Perpetual*: Captain Christy, W. Wilson Saunders, Reynolds Hale, Claude Levet, Bessie Johnson, Antoine Verdier, Baronesse Rothschild, Prince Claude Bernardin, Centifolia rosea, Clemence Raoux, Dr. Andry, François Michelon, Louise Peyronny, Madame Orapet, Madame de Ridder, Madame Marie Chrode, Marguie de Castellane, Maurice Bernardin, Pierre Nothing, Thym Hammarick, Thérin, and William Jesse.

**LILIAUM WALLICHIANUM AND LONGIFLORUM (W. H. O.).**—*Lilium Wallichianum* is a sub-species of *L. longiflorum*, but is much superior to it. The nurseryman are quite justified in describing it in their catalogue as a distinct Lily. *L. longiflorum* proper is a native of China and Japan, while *L. Wallichianum* is a native of the Himalayas of Nepal. It grows from 4 to 6 feet high, while the true *longiflorum* has a stem of from 1 to 2 feet, nor are the flowers in the typical species so large as they are in the other. About the same number are produced on one stem—namely, from one to two, but frequently the flowers are solitary.

**PRESERVING BERGAMOT ESPERME PEAR (J. V.).**—You either kept the fruit in a room that was too dry, or gathered it too soon. The cellar would be a more suitable place. The best way is to lay the fruit out carefully on shelves. It is no advantage to wrap it in paper or to cover it with cut hay.

**SEAKALE GROWING AND FORCING (Subscriber).**—Seakale may be increased by seed or from cuttings of the roots. The seed, first breaking the husks, may be sown in rich soil in April, in drills 18 inches apart, the plants to be thinned out to a foot distant in the rows. Some of these form good crowns the first season, and all are in fine condition for forcing the second season. Cuttings of the roots should be made in lengths of 6 inches, cutting the bottom of each in a tapering form, the top portion being cut straight across. These if made now and buried in light soil will form eyes by the spring, and the cuttings can then be planted to mature the crowns, thinning the eyes to one on each cutting. For forcing, the roots must be taken up and closely planted in soil placed on some fermenting material, as leaves or tan, and the top growth must be made in a perfectly dark place. The heat should range from 55° to 65°. If the plants are required to be forced under pots in the open garden, the seeds or roots should be placed in clumps, having three or four crowns in each clump, these clumps to be 8 feet distant from each other. The summer culture of the plants is limited to constant hoeings and copious supplies of water, and removing the flower heads as they come into bloom, preserving all the leaves on the stems. The soil must be deeply trenched and heavily manured.

**GRAPES SCALDED (R. H. H.).**—Your Vines have been kept too close, and especially air has not been given sufficiently early in the morning. The Vines also appear to lack vigour. Remove the surface soil from the border and replace with loam and bones, and surface with rich manure. This with judicious ventilation will improve your Vines another year.

**COST OF LABOUR (E. B. T.).**—We have no means of assisting you in your first question. Your second shall have attention next week.

**PEACHES ON OPEN STANDARD TREES (H. W.).**—It is not uncommon for the double-blossomed Peach tree to bear fruit, but we have not before found the fruit so highly flavoured as are those you have sent.

**VARIOUS (J. Sargent).**—The plant you refer to is the variegated Pear-shaped Gourd, not at all uncommon, and which may be had of any seedsman. The Red Antwerp Raspberry is a sweet one, and for the other Prince of Wales. A good outdoor Grape for a wall is Early White Malvasia if you wish a white one, and Miller's Burgundy if a black one.

**NAMES OF FRUITS (Gonsaught Subscriber).**—*Apples*: 1, Court-Pendu-Plat; 2, not known. *Pears*: 1, Marchal de Cour; 2, Achan; 3, Beurré Caplismont. (J. B.).—1, Transparent Codlin, a good old English kind; 2, Ganges; 3, Norfolk Stone Pippin; 4, Mutton Square, an old and valuable Lancashire variety. (E. D. O.).—*Crataegus coccinea*. (M. F. W.).—Fondante d'Autonne. (O. Merdon).—It is very like Crasane, but we are doubtful as to its being so. We will examine it and reply in next number. (T. W., Biding).—Pear, Beurré Rance; Apple, Ringwood Pippin. The Plum was so bruised we could not distinguish it. Plums for identification should always be accompanied by the young wood and leaves. (S. W. S.).—1, Beurré Diel; 2, Winter Nalis. (F. W. Pine).—1, Suesette de Bay; 2, Red Doyenné; 3, Louise Bonne of Jersey; 4, You have sent three distinct sorts under this number. One is Autumn Bergamot, one Vinesse, and one Red Doyenné. *Apples*: 1, Golden Reinette; 2, Ribston Pippin; 3, Golden Russet. (R. L. J.).—1, Beurré Diel; 2 and 4, Vicar of Winkfield; 3, Uvedale's St. Germain; 5 is malformed, but looks like Brougham; 6, White Doyenné. We cannot make out the others, they are so small specimens. The best work with coloured plates of Pears is Mr. Van Houtte's of Ghent. It is called Van Houtte's "Pomons." (Fur Hort.).—1, Red Autumn Galville; 2, Boston Russet; 3, Jolly Beggar; 4 and 5, not known; 6, Red Doyenné. (L. S.).—1, Cokham;

2, Lewis' Incomparable; 3, Ribston Pippin; 4, Cox's Orange Pippin; 5, White Astrachan; 6, Tower of Gammia. (J. Fairweather).—2, Bouvier Bourgmester; 3, Beurré d'Amant; 4, Doyenné Boussoch; 5, Emilia d'Hayat; 6, Beurré d'Alençon; 7, Winter Nalis; 8, Pesse Colmar. (Ohas. T. Hall).—1, Herefordshire Pearmain; 2, Biggs' Nonesuch; 3, Lodgecombe Nonpareil; 4, Cox's Golden Drop; 5, Pearson's Plate; 6, Keswick Codlin. The seedling is new to us, and is no doubt a good early cooking Apple. The *Alternanthera* were all shrivelled. (W. B. K.).—*Pears*: 1, Beurré Benoit; 2, Pesse Colmar; 3, Beurré Diel. *Apples*: 1, Callini; 4, Aromatic Russet; 5, Sturmer Pippin. (East Dene).—2, Fondante de Noël; 3, Beurré Sterckmann; 4, Duchesse d'Angoulême; 5, Thompson's; 7, Marie Louise; 8, Eater Beurré; 10, Glou Morceau. (Somerset).—1, Flemish Beauty; 2, Baronne de Mallo; 3, not known; 4, Doyenné du Comice; 5, not known; 6, Jean de Witte. (G. H.).—3, Nonesuch; 4, Braddick's Nonpareil; 5, Cobham; 6, Court-Pendu-Plat; 7, Autumn Pearmain; 8, Reinette du Canada; 11, Mère de Ménage; 13, Pile's Russet.

**NAMES OF PLANTS (Felix).**—The berried plant is *Solanum Capsicastrum*, and the fruit is not poisonous; the other is *Cyperus alternifolius*. (M. H. M.).—*Linum arboreum*. (E. J. S.).—The shrub is *Crataegus acutrolis*. The Ferns are without fruit, except 8, which may be a form of *Adiantum ethiopicum*. (C. W.).—Specimens insufficient. (A. S.).—1, *Adiantum cuneatum*; 2, *A. concoloratum*. (N. W.).—*Polystichum angulare*, var.; 3, *Asplenium* (Darce) Bichard; 4, *A. bulbiferum*, var. (S. Dowe).—1, *Fellex hastata*; 2, *Phymatodes* sp.; 3, *Adiantum pedatum*; 4, *Athyrium Filix-femina*, var.; 5, *Fellex crataeg*; 6, indeterminate. (W. H.).—*Quercus coccinea*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### AUCTION SALES.

We have received a letter from a gentleman asking for advice concerning the best method of selling a large portion of his surplus stock of poultry. He writes thus: "I have about 120 birds for sale, principally adults, and nearly all prizewinners. They comprise eighty hens, ten cocks, and about thirty chickens. They have been collected by me from time to time in the past twelve months from the best yards. I have determined to part with all those I do not actually want to keep for my own use; and now comes the question, Shall I sell them by auction? If so, when is the best time? Where is the best place? And what will be the probable sum they will fetch?" We hardly know how to reply to him, for it is a great question whether poultry auction sales do answer or not; anyhow, the queries raised by this gentleman have called the subject up, and as so many will soon be having a large quantity of surplus birds on their hands a few words about sales of birds and whole yards of poultry by auction may not be out of season.

The success of poultry auctions must depend, as in all such similar sales, on the quality of the birds, the company, and the place of sale. A good yard of birds, which must be really sold out-and-out, will very often bring a good company and realise good prices, provided only the nature of the sale is well known. But such auctions are very few and far between. We hear frequently that there are to be sales from celebrated yards, and then catalogues are issued describing the winnings of champion this, and the silver cups of champion that, but when the auction comes off we find there are large reserved prices on these champions, for they are never intended to be sold, and are only entered in the catalogue to make a display and to draw a company together. These auctions can never be said to answer, for even if amateurs and others less learned in poultry lore are brought together by the tempting baits offered in the shape of champion winners, which are really never meant to be sold, they soon have their eyes opened, and the surplus stock only realises poor prices. Such auction sales of poultry are seldom repeated, and can never be called a success, consequently we could never recommend anyone anxious to sell off a lot of inferior specimens to take such a course.

The next stage in poultry auctions would be a sale where the birds were *bond fide* surplus stock, entered as such in the catalogue, in company with baits of no sort or kind, except with of course the reputation of the owner as a breeder or exhibitor, and the highest bid in each case to be the purchaser, there being no reserved prices. Such a sale should answer, and the birds fetch fair prices if they come from yards of any notoriety, or are guaranteed to be of certain strains; still they frequently do not do so, and we have a remarkable instance in Lady Gwydyr's sale a week or two back at Ipswich. Certainly it was held rather too early in the autumn, and the auction was not sufficiently advertised; nevertheless, with the world-wide reputation the Stone Park strains possess we should have anticipated under any circumstances higher prices than seem to have been realised. If auctions do not pay where nearly every surplus bird has a pedigree to back it up, we can hardly expect them to answer when amateurs and the less-known fanciers adopt them to clear out their yards.

Then we come to another kind of poultry auction sale—viz., a final break-up of any well-known yard, when every bird will be actually sold to the highest bidder, and the establishment is to be broken-up for good. Poultry tradition will ever hand us down as an example of such an auction the sale of Lady Holmesdale's birds at Linton Park. Many remember that day,

when lot after lot of the finest Dorkings ever bred went at the fall of Mr. Elijah Smith's hammer to new homes in distant counties. We suppose there are very few fanciers who have not heard of it. Mr. John Martin might well be proud of the birds he had bred as he heard the sums gradually rise higher and higher. Yet those were no days of exorbitant prices. Birds commanded a steady sale, but the reaction had not then set in, and we did not hear of the prices then which we weekly know birds have fetched and are fetching in 1874 and 1875. Nevertheless we would not recommend fanciers retiring from the poultry world to have such a sale. We would sooner advise them to imitate Mr. Beachy when he gave up his yard of White Cochins and the trustees of the late Mrs. Williamson, and sell their birds privately in one lot. It is better not to ask such a large sum, and so make a private sale a certainty, than run the risk and incur the trouble and expense of an auction sale, for such events as the Linton Park sale, where all the birds sold well, are but of rare occurrence.

Next we come to the regular sales of poultry which are in the present day the most fashionable. We allude to the periodical poultry auctions in London, Manchester, Liverpool, and many other large towns. We think when breeders and others have made up their minds to sell by auction it pays them much the best to send their birds at intervals to the nearest poultry sale. In many of the big cities sales are held fortnightly, and the auctioneers have a fixed tariff of charges, supply baskets, &c. But we do not call even these sales satisfactory to the vendors. We have seen lot after lot of really fair birds go for 8s. 6d. or 4s. 6d. each, for anything like a good price is but rarely obtained. The birds are often crowded up in these sale rooms, and penned in small baskets, consequently they never look at their best. Of course there are instances on record of individual birds obtaining good prices at these sales, but we think it is far from the rule. But were we obliged to sell by auction we should do so by means of some such sale. It would then be to our interest to advertise our birds as about to be sold in such an auction room, apart from the general advertisement of the auctioneer; and we should naturally choose a date in November or December, when the young birds would be matured and the adults in bright feather.

We are of opinion that at the root of the evil is the fact that so many inferior birds are sent to the auction sales, birds which really are only fit to put into a pie. Faulty and badly-marked chickens are not half killed off enough in their early youth. We went the other day to one of our most successful exhibitors' yards, and the higgler had actually just bought of him eighty pure-bred well-marked birds, their faults being quite of a minor kind. That is the way to do well. Kill off the most inferior specimens, and devote more time, and food, and space to the remainder, and we shall then find the prices of ordinary specimens at auction salerooms and everywhere else much better, and much more faith put in the quality and breeding of the birds found there. We are quite sure too many poor specimens are allowed to live, and hence we find the wretched rubbish we do at these general auction sales. Good birds can always fetch a good price, and we are certain expenses would be made to meet much more easily if the chicken ranks were only thinned in good time—as soon as ever the bad can be discerned from the good, for then the extra care the remainder would receive at the hands of the attendants would make them finer birds, and more valuable for whatever purpose they are to be devoted to; for, quoting a gentleman who sold his eighty chickens for killing purposes in one lot and had 2s. 9d. each for them, it paid him much better to sell them so and to get rid of them entirely out of the chicken world, than to send them to an auction where he would perhaps obtain 6s. or 7s. each and have to pay for carriage and railway journey of the attendant, besides the auctioneer's fees. And once more: The trade in prize poultry is much weakened by the broadcast dispersal of inferior specimens throughout the various poultry yards in the country, for they, in their turn, producing even less worthy specimens, actually choke the fancy with mere rubbish.—W.

### SECRETARIAL SHORTCOMINGS.

I WISH secretaries could be induced to pay more attention to the despatch of catalogues. I mention a recent instance of carelessness which is not, I am afraid, singular.

When I sent my entry fees to Nottingham I sent at the same time the money for a catalogue; thinking it not improbable that the Secretary might forget that I had done so, I wrote to remind him of it when I sent off the birds. No catalogue came, and I wrote again, and with the same result.

Secretaries might with advantage recollect that exhibitors are apt to apply the proverb, "A feather shows which way the wind blows," and that they are not likely to trust their birds to shows where inattention seems to be the rule.—F. G. DUTTON.

GREAT NATIONAL POULTRY SHOW, CRYSTAL PALACE.—We understand that one of the cups in the special classes for

members of a Columbian Society, &c., has been presented by Mr. R. Fulton. As it is especially intended for amateurs he has signified his intention of not competing in the class.

### THE OXFORD POULTRY SCHEDULE.

I VANTURN to think that one class does not receive fair play at the hands of the Committee. I allude to the class for Sebrights, in which the first prize is only £1 10s., and the second 15s., whilst in most other classes there are three prizes of £3 8s., £1, and 10s., and in none is the first less than £2 2s. Even the Selling class for Bantams any variety has a better prize offered. This seems to me, as an interested individual, a slight upon this new favourite breed, and the only blot on an otherwise liberal prize list. I trust the Committee will do something to put us exhibitors of Sebrights on an equal footing with others.—JAMES W. LLOYD.

### CRYSTAL PALACE POULTRY SHOW.

THE little volume of the "Great National" has again come to hand, and the contents are indeed startling. The rules and regulations come among its first pages, and we find most of them *in statu quo*—so much so that there is nothing new to say of them, for these worthy people will not even allow the use of double baskets. We have so lately urged the advantages of this arrangement in these pages that we will say no more here; and only hope that the authorities will realise, before it is too late, the advantage it will be to them to alter this rule as their rival sister did after her schedules were issued.

Next we come to the Judges, and a goodly muster they make, for we read who the gentlemen are to be, and they comprise nearly all that exist of any note. The names might have been omitted for all the good they do, as exhibitors will have no knowledge as to which of the gentlemen is to award the prizes for the various classes. Had the Committee said Mr. So-and-so will take the Dorkings, and Mr. So-and-so the Brahmas, and so on, we should say the National had indeed set the ball rolling in the way it should go. Entries close on the 18th inst.

We next come to the cups. Forty-five pieces of plate, or equivalent in money value, will be given among the poultry classes, beginning with one value £21 for the best pen in the whole Show. This is with a vengeance returning to the valuable champion cups which we advocated a few weeks ago. £350 is spent in cups alone on the poultry department, which must make this Show more gigantic than ever. Wherever will Mr. Billett procure his pens from?

Dorkings come first on the list. We find thirteen classes with forty-five prizes among them. White Cochins come off as well, but we think Black Cochin cocks and hens should have been divided. From the fine show of Black chickens at this Exhibition last year we must all know there will be lots of good old birds about this season, and we think they should have consequently partaken of like favours as White and Cuckoo Dorkings, which are now divided as to sexes in this Society's schedule for the first time. Brahmas, too, are well cared for. A new feature is a class for mottled-breasted cockerels, so we conclude the former class is for Black-breasted birds only, though the schedule does not state this. We only mention it, knowing from experience how many fall into these little mistakes, and are consequently greatly disappointed afterwards.

The other classes are well arranged and classified, but most assuredly Malays should have had two classes. We had hoped we should find one for Whites or Piles, but if this was too much to expect we did trust to find a class for gentlemen as well as one for the ladies. Polish, Leghorns, Silkies, and Andalusians all have classes and good prize money. We are glad the latter breed is provided for, and wish we could say the Minorcas were here able to do battle in a class to themselves, which we believe they would have filled right well.

Bantams have fourteen classes, nine of which are for Game. We shall expect to find a grand array. We are pleased to notice, too, a class for the quaint, old-fashioned, booted Bantams. Ducks are well seen to, but Calls have no class. Resent it, Call fanciers, for if you send four birds in class 116 against the ornamental waterfowl it will be only throwing money away. The Sale classes are legion, and we shall expect to find really good birds here, as we always do.

Pigeons are as nobly provided for as the poultry, forty cups of all values being distributed among the classes. The Draughts alone should make a show, for they have no less than fourteen classes. Jacobins, Fantails, Owls, and Turbits are all divided as to colours and should make a fine company. There is, as a finale, a class for the best collection of four pairs of not less than two varieties, and two classes for collections open to members of societies only.

We have made no mention of the special poultry classes, which seem to be causing so much excitement—viz., for untrimmed or unplucked specimens, as we prefer waiting to see what the results will be there, in the latter class especially, which is for all varieties not Game. But as we read in a con-

**ANY OTHER VARIETY OF BRITISH BIRDS.**—1 and 2, Cleminson & Ellerton (Starling and Thrush). 3, W. Warwick, Darlington (Thrush). *See*, W. & C. Barnard (Brambling).  
**Selling Class.**—1, G. & J. Mackley. 2, H. Brook. 3, Cleminson & Ellerton. *See*, J. Horn; J. Atherston; Cleminson & Ellerton. *See*, B. Pearson; T. Tenniwood; T. Jobling; Cleminson & Ellerton (3). *See*, J. Adams; W. Howard.  
**Judges.**—Mr. G. J. Barnesby, Derby; and Mr. R. L. Wallace, Berwick-on-Tweed.

### LIZARD CANARIES.—No. 8.

There is more difficulty in bringing a perfect-feathered and capped Lizard bird to the post in proper show trim than those of some other breeds. I know of no breed except the "London Fancy," where the loss of a wing or tail feather becomes such an eyesore to a judge of birds, and the owners likewise—those who love to see their birds not "out of feather." The grey tip that accompanies the end of a feather to supply the place of a lost one, tends to mar the regularity of feathers somewhat. In some, especially Silver birds, it is the most perceptible.

Mealy or Silver birds are generally inclined to be of a stouter build than Jonques or Golden specimens, otherwise there is very little difference except in the colour. As "Golden" is the recognised term by which the one kind is known, by this rule so ought they to be considered by those who have to adjudicate upon them, and who ought not to let their knowledge of a rich Golden-spangled specimen be led astray because a Golden or Jonque specimen (or, at least, one exhibited for such in a class), should happen to be as deep in colour of cap and lacing, or edging of spangles, as a deep pepper-coloured Norwich bird. A little carelessness in this respect, in what I may term mere surface judging, may have equally ill effects respecting good and inferior-bred Lizards as it may have upon Norwich birds. There are many nice points to guide one over Lizards. It is true that the deeper the colour of a Golden bird the more value it is, but when a bird presents a colour with the aid of pepper the reverse of golden I look upon the destruction of the colour as grave an error as when the proper rich golden tint is not fully attained. Of course, colour is but one point, although an important one, and a bird being highly coloured with pepper could not be cast aside if fully possessed with all other points. It should be the consideration of the whole, and the bird which gains the most points that should win.

The cap of a Lizard should be of good size, and oval in formation, extending from the dark beak to the back portion of the crown, where it should terminate somewhat square, neither to run or extend down the neck or at each side of the cap. On each side of the head the cap should reach the eye-lids, which should be dark. From the neck the spangles gradually increase in size until reaching the back, where they should be fully and very regularly developed. The legs, feet, and web, and stalks of wings and tail black. A good bold headpiece is much preferable to a narrow one, for then the cap of a bird appears to greater effect. The chief point is cap, then spangles. The following points will guide those having a fancy to breed and exhibit:—  
*Beak*, the darker the better.

*Head*, the crown should be flattish and wide with size throughout.

*Cap* should possess purity, rich colour, and magnitude of form with great regularity, coming to the beak in front, and to the back of the crown behind, and not lower than the eyebrow or lid, which should be dark.

*Neck*, short and thick, with small clear spangles, beginning at the back of the cap and gradually increasing in size towards the body.

*Back and spangles*, wide across the back, and clearly and thickly spangled, the boldest being in the centre, and the others gradually decreasing towards the sides and upper tail-coverts.

*Wings and tail* should be black, the bastard wing feathers particularly; the others (pinions) black in stalk and web, and fringed with golden or silvery white according to class.

*Throat and breast*, golden or silvery according to class, and regular throughout, the richer the golden the better.

*Chest and body*, the former wide, and the body of good size, the bolder the better.

*Legs and feet* black, and nails not twisted-awry.

*Feathers* very close, and not deficient or pied, with the underneath fine of the Golden-spangled a bluish black, and the fine of the Silver-spangled more of a dark grey. In the yellow portions of the Golden-spangled the richer the colour the better; and in the Silver-spangled the colour should be more like newly-cast virgin silver, especially in the cap. It is a fault, however, when a Silver bird approaches nearly midway to a Jonque, which they will do sometimes; such are likely to be disqualified, and very properly too, as an undecided-coloured bird is unworthy of a prize.—GEO. J. BARNESBY.

**SALE OF PRIZE FOWLS FROM LADY GWYDYR'S.**—The following are the prices realised for some of the best of Lady Gwydyr's birds recently sold at Norwich.—A splendid pair of Buff pullets were secured by Mr. H. Bryant of Whitton for 32s., and a fine

White Cochon adult cock was knocked down to the Hon. and Rev. F. De Grey for £1. Lot 41, a pair of valuable Cochon hens, after a keen competition were purchased by the same gentleman for £2 12s., and he also purchased a pair of milky-white Cochon pullets of pure extraction, and cheap at two guineas, the price given. Lot 84 a Dark Brahma cockerel and pullet was bought by Mr. Field for 19s. Lot 91 consisted of a handsome pair of freckled-plumaged pullets which went for 25s. to Mr. Bagshot. Lot 92, a pair similar in description, was bought by Mr. Lovely for 20s. Dr. Holden became the owner of two Light Brahma hens imported from America, for 11s.; and a pair of superior Dark Brahma cocks, noble-looking birds, went to Mr. Melton for 25s.

### EXHIBITING POUTERS.

THE schedule of the Kilmarnock Exhibition, which has just been issued, shows the usual liberality and enterprising spirit of the Committee. Year by year some improvement is effected for the benefit of exhibitors, which no doubt contributes to the swelling of the treasury.

I wish to call the attention of Pouter fanciers to an important addition in their classes, which may be overlooked or misunderstood. I refer to the new classes 47 and 48 in the schedule. It will be observed that the other classes are for standard-pied birds, while these latter bear the designation Any other Pouter. The intention is obvious. The words "standard pied" need not mislead anyone to the belief that they aim at strait-lacing in the matter of the pied marks. The utmost usually seen in that direction on a standard specimen is mere approximation; therefore no one need be deterred from entering any bird that has a chance of winning. The new classes are evidently intended for birds for which no other class is provided, as well as for those which, though possessing all the essential elements of a Pouter, are yet disqualified in some particular from competing in the standard classes. It is unfortunate that we are still in the dark as to what these disqualifications are, for though I raised the subject several months ago no reply was evoked.

I am perfectly certain that Mr. Huie, if he still holds his former opinions, will hail the innovation as a step in the right direction. It declares in a practical manner that the Pouter is a bird of shape, and supplies what he so urgently pleaded for—viz., an opportunity for the young and the poor fancier to obtain a small share of success and encouragement.—D. McVAUGHY, Kilmarnock.

### A RETROSPECT.

THOUGH the apirians of Great Britain have to lament an unfavourable season for bees, and therefore a poor harvest of honey, many of them are virtually enriched by another year's experience; and all know that experience is the best and most effective teacher. I am thankful that what little I know of bees and their management has been gained from experience and not from books. Indeed, I never read a book on bees till I began to write about them thirty-five years ago. Huber once said to a friend, "I am much more certain of what I state than you are, for you publish what your own eyes only have seen, while I take the mean among many witnesses." I am convinced that the intelligent readers of this Journal would trust and prefer the evidence of their own eyes to "the mean among many witnesses," for facts are more trustworthy than plausible guesses and opinions.

During the present season we have had recorded by Mr. Campbell another case of two fertile queens living together in a hive belonging to a neighbour of his. Mr. O. says the hive "was filled by a first swarm last year, and headed by a queen three years old. In May this year the owner discovered a young queen going abroad on her marriage flight; but as the bees often hatch a young queen when the reigning one begins to fail in her powers of reproduction, this circumstance was taken little notice of at the time. However, about four weeks after, the owner came to me and said that his young queen was a drone-breeder, filling the brood nest with young drones. I went to assist him to drive the bees and take out the objectionable queen. On driving we found the old one and young too. The old one was removed, and the young one with the bees returned to the hive. The drone-breeding was then discontinued. This is of very rare occurrence, as a young queen generally kills the old one as soon as she is hatched." On this phenomenon I shall make no comments at present, the object being to put the reader in possession of few facts and figures that have come before our notice.

One writer has stated recently that bees live only six weeks in summer, and that the young destroy the old bees and push them out of the hive. I am sorry that the statement has been made, for no statement could be much more incorrect. After a little more experience the writer, I think, will acknowledge his mistake. Bees live nine months, but many of them are worn out with hard work in summer, and lost in stormy and showery weather before they reach their allotted span. I have had a

swarm that worked well for three months in summer without breeding, and at the end of that time the bees seemed about as numerous as they did when they were hived. At the end of the season the bees were destroyed, and the combs (all virgin), were taken from the hive.

One other point in the natural history of bees should be noticed here—viz., the fact that the working bees assist their queens in the distribution and setting of eggs. I have seen instances of it in hundreds if not thousands of hives. During the present year another apiarian saw the bees in the act of removing eggs from one cell to another. The scepticism of many has now been scattered to the winds, and it is to be hoped that we shall hear no more of narrow slits between hives and supers being used to prevent breeding in the latter. If bees wish to breed in supers they will carry eggs into them. It is not narrow slits that keep bees from breeding in supers.

We now come to notice the season and harvest of 1875. The season has been more favourable in some districts than others, but taking the whole of Great Britain from the Land's End to John o'Groat's the season has been an unfavourable one for honey-gathering. In our own district, call it the Manchester one, we have had prevailing north winds and wet weather. Swarming, though earlier than last year, was rather later than is usual, but owing to unfavourable weather swarms had to be fed to keep them alive. Swarms that were not taken to the moors have had to be fed with syrup. Those that went to the moors laid up great stores of honey during the last fortnight of August. A few of the best swarms rose in weight to 80 and 90 lbs. each. The average weight of first swarms in modern straw hives would be about 70 lbs. each. Mr. Thorp of Sale took above £8 worth of honey and honeycomb, and sold two hives well filled for £4 from his two stock hives—in other words, £10 income from two hives. The bee-keepers at Carlisle in Lancashire (my native place), have to take second or third place this year. Not a swarm in the parish has reached 90 lbs. At the end of the clover season some of them were 50 to 60 lbs. each, only one 70 lbs., but owing to the weather being unfavourable they did not improve on the moors. Hitherto the Carlisle men have stood in the forefront with swarms ranging between 100 lbs. and 150 lbs. each, the accounts of which were sent annually to me by Mr. Robt. Reid, lately deceased. Mr. Henshilwood who has kindly sent me an account this year, and all the rest of the bee-keepers there, have sprung-up since I left Carlisle.

Last year the apiarians of Aberdeen and Banffshire were in the van of progress and success. This year two reports have been sent to me from that quarter, one by Mr. George Campbell, the other by Mr. James Shearer. Mr. Campbell considers "the present year the most unfavourable for bees, excepting 1845 and 1860, that he has experienced during a period of thirty-three years' practice amongst them." Last year he had two swarms that weighed 126 lbs. and 128 lbs. respectively. One he sold to a neighbour, but both of the hives were kept for stocks. The one he kept himself consumed 24 lbs. of honey during the winter months. It yielded a monster swarm of 9 lbs. on the 7th of June this year, which filled a hive 18 inches wide and 16 inches deep, but weighed only 81 lbs. at the end of the season. The first swarm from his neighbour's hive weighed 50 lbs. only. The bees of both are Ligurians.

Mr. Shearer of Cairnie, Aberdeenshire, has sent me his report, which is more satisfactory and comprehensive. He says, "The British bees have beaten decidedly the Ligurians this season in our quarter." "I believe," he says, "the season has not been very good, and our success must in great measure be attributed to good management. My first swarm, 6½ lbs. of bees, came off on the 25th of June. The weather thereafter continued so unpropitious that, to prevent starvation, I gave the swarm 7 lbs. of sugar. On the 1st of September it weighed 105 lbs. Another, which swarmed on the 28th of June, 5 lbs. of bees, had 5 lbs. of sugar and rose to 84 lbs. I had a stock hive which gathered 12 lbs. on the day before it swarmed, and 5 lbs. on the day previous, making 17 lbs. in two days. The average weight of my first swarms was 78 lbs. gross. Mr. Alex. Cockburn, Shenwell, had an artificial swarm on the 3rd of July which reached 142 lbs. on September 1st. A second and a third swarm came naturally from the same stock, showing that too many bees were not taken from it to make the first swarm. The skep of this swarm was 20 inches wide and 24 inches deep—one of Pettigrew's largest sizes, but it was not quite filled. The swarm received no assistance by feeding or otherwise, and the bees were the common variety. Mr. Robert Gordon, Mains, Gartley, in a note to me says he considers this has been a bad bee season. In some quarters his statement as to his last year's hive being 164 lbs. was not credited; he had his hives weighed as carefully as before, and in the presence of visitors. Natural swarming commenced on the 3rd of July (sixteen days later than last year), and ended on the 15th of July. His hives attained their greatest weights between the 17th and 24th of August. The weights include hives, ekes, and floorboards, which last year averaged 19 lbs.; this year, owing to greater size of hives, they average 17 lbs. The heaviest stock hive weighs 91 lbs., the lightest

65 lbs., average 76 lbs. 6 ozs. The heaviest swarm 144 lbs., lightest 88 lbs. 12 ozs., average 71 lbs. 2 ozs. The heaviest turn-out 99 lbs., the lightest 54 lbs., average 85 lbs. 6 ozs. Two of the turnouts gave swarms, the others were nadired. The 144 lb. hive was composed of (filled by) two swarms which united in the act of swarming. The unfavourable season will account for the deficiency of weights as compared with last year." Such is Mr. Shearer's report of bee-keeping this year in the neighbourhood of Huntley, Aberdeenshire.

Mr. George Fox of Kingsbridge, Devon, informs me by letter that his "Good honest black bees gave him a super this year which weighs 80 lbs. nett, and that Mr. Prout, ticket collector at Kingsbridge Road-station on the South Devon Railway, has taken a super 80 lbs. from a common straw hive." I have long considered Mr. Fox the most successful bee-keeper in the south of England, and a most honourable gentleman. I regret exceedingly that his super was disqualified (owing to its weight), at the late Crystal Palace Show. Mr. Fox naturally feels aggrieved, and informs me that "the super was honestly worked to the backbone," and hopes "the decision of the Judges is not final." He has received many expressions of sympathy, which tend to allay the irritation experienced in this matter. —A. PATTENAW.

## BEE HOUSES.—No. 2.

MIGRATING in 1853 to Tasmania I began bee-keeping anew. There my bees were kept in boxes on single stands in the open air, nor had I occasion to try bee houses during the four summers I spent in that beautiful island. The year 1858 found me once more settled in England. All that summer and autumn I was house-building, nor did I fail to make provision for a window apiary in a small room at the end of a projecting line of offices looking into the garden, which serves the purpose of a carpenter's workplace. Here I have a bench and tools of all sorts, with a convenient loft overhead for stowing away innumerable things. The one window in it is large enough to accommodate six colonies worked on the storifying principle in two rows. Each colony has a communication with the open air by a tunnel through the woodwork. The panes of glass in this window are darkened at pleasure, so that I can admit light into my tool house when I like, or shut it out whenever I have occasion to liberate bees from super or hive. In this case the door is open ajar, and the light attracts them thither, and my den is soon free of them. Besides this, which is called *par excellence* "the bee house," there is room for four more colonies on a couple of shelves in a fowl house, situated some 60 yards distant. These are managed precisely in the same way, except only that as the house is "weather-boarded," the communications with the outer air are out in the woodwork.

Requiring more room under shelter for my bees, I erected a shed three or four years ago in another part of my garden large enough to hold eight colonies. This is open to the air on every side, consisting only of uprights of oak and sleepers (under ground), with a roof affixed to a wall-plate, as in my old Herefordshire bee house. There are two shelves on which the hives rest, four in each row. As it is situated in the most sheltered part of my garden it generally escapes rain, but, it being quite open, the lower hives in particular often catch the drifting rain from the most exposed quarter.

On the whole, my experience leads me to give preference among all sheds and houses to what I have called my "window apiaries." These are really as faultless as any receptacles for housing bees can be, for here no enemies can attack them, and they are absolutely safe from damp and hurricane; and here are they most easily to be managed. No disturbance of one hive affects its neighbour so as to annoy the operator, and here feeding can be carried on to any extent without excitement in the apiary, and with the greatest comfort to the operator.

In my little book on "Profitable Bee-keeping," published by the S. P. C. K., and to be had at all its depôts, there is a woodcut of a simple shed for cottagers, to which I give the preference of all my other sheds and houses. It may be made of any length, and is very convenient, and gives good shelter, from its being low on the ground and well admitting of one row of hives.—B. & W.

## OUR LETTER BOX.

HAMBURGERS FOR EXHIBITION (B. M.).—If your birds are well grown, and have gone on without a check, you may show them, the more so that you probably have yet a month before you. You must choose them all with faultless feet. The hens should be bright coloured, and the penning should have a metallic lustre. Their hackles should be clear, and their tails as much pencilled as possible. Cocks and pullets must have good combs, quite firm on the head, full of points, with pike turning upwards behind. The cock's tail should be black, but each feather edged with gold. Choose birds of rich colour, as the washed-out hue has an air of poverty and does not recommend itself.

POULTRY WITH SCALY LEGS (H. W.).—The scaly legs you speak of are known as the poultry elephantiasis. It is quite a modern complaint and a great nuisance. At first it attacked only Cochins, but now Orpingtons

**Brahmas, and Game seem the only birds that do not suffer from it.** The only treatment we know is to keep the legs constantly moist, either with citron ointment or with sweet oil. It is very difficult of cure, and the sooner it is taken in hand the better.

**KEEPING GEESSE WITHOUT A GRASS RUN (S. E. L.).**—Your letter is hardly explicit enough. Do you mean to keep Geese with a view to fattening them, being bought at an age when their early troubles are over, or do you mean to keep them as stock, and to breed from them? If you wish to have them as Geese for the table, they may run in the yard you describe, and be put-up in a smaller space to fatten as they may be wanted. It is hardly possible to breed Geese profitably unless they can have a grass run; it is their natural baby's food. All Geese of every European breed want grass when young. Geese are generally largely bred in the vicinity of commons for this reason. If there be such places in your neighbourhood you will do better to buy goslings than to breed them. They are easily fattened on bran, oats, and meal. If you determine to keep Geese they must be liberally fed with grass cut in large sods and put in water, or on dry spots in a yard.

**HEATING POULTRY HOUSES (E. E.).**—We do not care to heat our poultry houses, nor would we have them heated if it were done gratis. If you differ from us we believe the best plan is to heat with hot water. The chill the birds experience when they leave their heated house for the cold outside atmosphere is very detrimental. We prefer to increase our food, and to give it of a more stimulating character, as scraps of all sorts of meat; feeding three or four times per day on soft food, and above all feeding the first thing in the morning at break of day, and the last thing at night. When snow is on the ground, either to feed on a spot that has been carefully and scrupulously cleansed of snow, or in their houses. Snow is to all birds a violent purgative. It must always be borne in mind that although poultry is somewhat artificially treated, yet it partakes to a certain extent of the nature of Game. Except in very long-continued snow or frosts we do not find Pheasants, Partridges, or Grouse affected by the weather, and their feeding is far more precarious than that of fowls. The latter are therefore better able to bear it than their wild brethren.

**SWANS (A Lady in Cheshire).**—It is often the case that Swans will not take to the water they are intended to adorn when there is other water near. Close observation will end by discovering the cause of the preference. There is a cause—either some weed of which they are fond, or a larger space of water, or more shelter. The rule with all animals when they are required to keep at home is to feed them so well that they have nothing to seek. They are then always full, they grow fat and lazy, and stay at home. It is seldom Swans walk as far as the space you mention, and if they are properly plumed they cannot fly. When they have the use of their wings they will at certain seasons of the year fly long distances from home. They generally return, but they sometimes meet with accidents.

**TRANSPORT OF POULTRY (J. C. H.).**—We are unable to give you the desired information, and advise you to write at once to the Secretary of the Show you name.

**PIGEON HOUSE (Constant Subscriber).**—The more room you can give the better for the birds. It is especially desirable to make a house lofty; it should also be light. In giving measurements we do not say the space is absolutely necessary, but, if you have it, it is desirable. We would make it 10 feet every way. A good flooring is made by putting down liquid tar and covering it with small sifted gravel; when cold another fine coat of tar and another coat of gravel. This makes a surface that will bear sweeping. For purposes of cleanliness the floor should be perfectly even, and for the same reason the sides of whatever material should be smooth. There should be no harbour for dust or vermin.

**LAME PIGEON (W. F. C.).**—We can only advise you to keep the bird by itself. The leg is probably injured in some way, and will most likely benefit from rest.

**SPOTS OF BLOOD IN A CANARY'S CAGE (Joe).**—The spots of blood in the bird's cage may be accounted for as follows:—Birds upwards of one year old at this particular season cast their quill feathers (wings and tails), and the tapping or injury to either would cause them to freely bleed. In an early stage of the feathers shooting forth they are heavily charged. On the other hand, the blood might have proceeded from the bird's claws, for they are likely to get trapped in a crevice, or become entangled in the wirework or the ends of the perches. If the quills and claws appear all right then we will suppose that the bird might have ruptured an artery, and to prevent becoming unfatigued with the blood in the throat would naturally shake its bill and bespatter the cage. In either case the bird may be thus treated: If the blood arises from the quills, remove the bird from others, and nature will speedily effect its own cure. If the claws have become injured bathe them in salt and water. If an artery has been ruptured let the patient be kept quiet, and not excited or hurried. In the bird's fountain put half a teaspoonful of brandy, and a piece of salt the size of a bean, give a cold bath, and until the bird recovers strength a little bread-and-milk diet. It is not an uncommon occurrence for Canaries to throw-up blood. Fright and sudden excitement is the cause, and fits often ensue. When approaching a cage to catch a bird it is always better to give it slight notice by familiarly chirping at it. Kind familiar treatment is essential to all animal life, and Canaries quickly appreciate it.

**WRIGHT OF COMB—COVERING HIVES (A Young Apianian).**—The late Baron Liebig, in the appendix to his work on "Animal Chemistry," says that "bees have to consume 20 lbs. of honey to make 1 lb. of wax, and 1 ox. of comb holds 1 lb. of honey." We have not tested the matter, and therefore cannot vouch for the accuracy of Liebig's assertions. The quilt and carpet arrangement for the tops of hives is ineffectual. We advise you to remove the old carpets from the crowns of your hives, and put something better in their places; you cannot easily find anything worse.

**DRIVING BEES (A Constant Reader).**—It is rather late in the season to form an apiary of large straw hives by feeding swarms put into them. You have succeeded admirably in colonizing three swarms in one large hive and causing them to build an abundance of comb. At this late season we think you would do well to let the bees remain as they are, and put the swarms next year into the large hives. But if you are determined to people another large hive, take the combs out one by one and sweep the bees off them with a hand brush into the large hive. This you can easily do either outdoors on a warm day or in the conservatory by candlelight. But to attempt to feed the bees afterwards in the conservatory would be risky. Thousands of them would probably be lost by flying against the glass.

**FLAKES OF WAX (A Novice).**—The wax dust which you gathered and sent for inspection is composed wholly of flakes of wax which ooze from the abdomens of bees while they are building combs. All swarms lose some of the flakes (which fall on the board), in the operation of comb-building. They do not pick-up or use what falls from them in this work. Your hive is quite healthy, and if it contains 12 or 15 lbs. of food now, and is well covered, it will live through the winter.

**QUINCE MARMALADE (J. F.).**—Gather the fruit when fully ripe, and of a fine yellow; pare, quarter, and core it; put the quinces into a saucepan with a little water, and set them on the fire until they are quite soft; then take them out, and lay them on a sieve to drain; rub them through and weigh the pulp; boil an equal quantity of sugar to *petite case*, then add the pulp, and stir them together over the fire until it will fall from the spoon like a jelly. The marmalade is then fit to be put into pots, and when cold cover them closely.

**QUINCES, COMPOTE OF (W. G.).**—Take six quinces, cut them in halves, and core them; scald and pare them neatly. Put some clear syrup into a preserving-pan, with the juice of a lemon; when hot add the quinces, and give them a boil together; drain the fruit, arrange it in the compotier, leave the syrup to thicken a little, and pour it over the quinces.

## METEOROLOGICAL OBSERVATIONS.

## REMARKS.

- 6th.—Fine all day; at times very bright.  
 7th.—A very fine day throughout.  
 8th.—Hazy early, but a fine day afterwards, though there were a few drops of rain at noon.  
 9th.—Fine till noon; after that time rather showery, the wind rising and being at times very high; and great fall in temperature.  
 10th.—Fine till 5 P.M., then showery at times; the fall was heavy, especially about midnight.  
 11th.—Fine morning; a sudden and very short thunderstorm at 10.55 A.M., the sun shining quite brightly when it commenced, and though dark for a short time soon clearing off.  
 12th.—A very fine day but cold, though there was not much wind.  
 Rapid fall of temperature at the end of the week, with what is a very unusual accompaniment—viz., low barometer and west wind.—G. J. SYMONS.

## COVENT GARDEN MARKET.—OCTOBER 13.

No alteration in prices this week. Peaches and Grapes from Holland have been arriving in very good condition, also Pears from France, consisting of Duchesse d'Angoulême, and Glou Morceau. Cobs have been in good demand at slightly better prices.

From observations taken near London during forty-three years, the average day temperature of the week is 50.5°; and its night temperature 50.2°.

## SOIL AND CLIMATE IN RELATION TO PRACTICE.

**D**oubt the nature and condition of the soil must exercise a material influence upon the climate; apart from this, the treatment of soil for all purposes of cultivation is a matter of such prime importance that a clear understanding of the matter in its relation to ordinary practice is most desirable. I have already in former papers told something of my struggles in bringing what I have termed the worst soil in England into a suitable condition for vegetable culture, and I shall have something to say further on about what has been done to it for fruit-culture, but before doing so I wish to say a little about what Mr. Taylor has told us of the soil at Longleat. Evidently it is abundantly fertile, but then its mechanical condition is about as bad as can be, and I should much like to know what has been done, or what it is intended to do, to ameliorate its crudity.

In Mr. Taylor's first paper, on page 197, he states that "the soil is extremely cold and heavy, the atmosphere humid, and frost visits us every month of the year;" and on page 285 he states that the "soil is almost too heavy to be called a soil at all; it is clay, and such heavy clay too that if it lies a year or two unmoved it is almost impervious to air, and becomes, consequently, sour." Thus, then, we have very clearly set before us an evil, but we have no statement of a remedy, which impresses one as being so highly important and necessary. What else, I ask, could be expected to prevail where there is such a cold, heavy, sodden, inert soil, but a still colder and most humid atmosphere, leading to frequent frosts? I have not seen Mr. Taylor's garden, but judging solely from his own statements I am forced to the conclusion that he is either unaware of what a radical change may be effected in such a soil by the action of fire, or that he is prevented by circumstances from applying the remedy. Burnt clay and a thorough system of drainage would surely effect a marvellous change in this cold heavy soil. Certainly if so treated it never could afterwards settle into an inert mass or become waterlogged. Mr. Taylor questions whether the condition of the trees at Oldlands is entirely owing to cultural skill. Certainly not. Let me, however, state clearly the original condition of the soil, its preparation for the trees, and its subsequent management, together with that of the trees; it being evident from the numerous communications on the subject which have reached me that many Journal readers are anxious for further information on this subject. But let them not fail to remember that each case must be treated solely on its own merits, and that if I had to make a garden in another place there would be no line-and-rule work—no slavish following of former plans, but rather such an adaptation of means, such a mode of culture, as the circumstances of situation, soil, and climate appeared in my judgment to require.

The virgin soil here is a very poor thin loam, containing such an unusually large per-centage of silicious sand that a heavy shower will beat it into a compact mass, drying

into such hard clods that they have frequently to be softened with water before they can be broken up. The subsoil is a mixture of marl, clay, and silicious sand of a heavy close texture, and so adhesive as to form a puddle for pond bays nearly equal to that of pure clay, altogether forming about as unsuitable a staple for fruit-culture as could be found; so thoroughly was I convinced of this, that as the station holes (6 feet square by 8 feet deep) were excavated the entire mass of material taken out was carted away to help to form a viaduct then in course of construction.

Now, to fill the holes with good soil and to plant the trees might appear a very simple matter, but in reality it was not quite so simple. The entire future of the trees depended so much upon how this was done that results had to be carefully considered, the first shower showing plainly that without an outlet for water the holes would soon prove just so many death-traps to the roots. A row of common 2-inch drain-pipes was therefore put across the bottom of each hole under a layer of 6 inches of rough stones and connected with the garden drains, which had previously been made 4 feet deep and 80 feet apart; the remainder of the holes being filled with turfy loam brought from a distance, a little manure stirred in with the upper portion, the trees planted, and the surface mulched with a little fern. Thus, then, the trees were ready for a start, but for a start only, and not for a prolonged existence without future attention to the soil. It was calculated that the trees would require about three years to attain sufficient vigour and maturity for producing really good fruit, that the stations would afford sufficient nutriment for this, and that by then the soil surrounding the stations would be sufficiently improved by culture to afford an additional food-supply for the roots. The calculation was a correct one. Trenching, repeated dressings of manure, wood ashes and gritty matter, such as coal ash and shattered brick, have converted the once-crude substance into an excellent rich and fertile soil, into which the roots have spread with a rapidity that is admirably in keeping with a vigorous wood-growth. During the present year sewage has been given frequently, especially while the fruit was swelling, and also after it was gathered, to impart full vigour to the fruiting wood of next year.

Thus much for the culture of the roots. Now for that of the branches, which were pruned according to strength to lengths of 12 to 20 inches at the time of planting. The first season's growth was trained upwards at rather an acute angle, so as to impart as much vigour as possible; only the breastwood being pruned away as it appeared. The winter pruning consisted in slightly shortening the leading shoots and thinning and shortening the side growths, taking care to leave the lowest shoots longer than the others. Subsequent pruning may be briefly described as consisting of thinning any growths immediately a probability of crowding was perceptible, occasionally entirely cutting away a too rampant shoot in the centre of a tree, or if good wood was wanted there to obtain it during the growing season by pinching off the top of one or two of the strongest shoots, and causing

them to put forth the requisite number of laterals. To maintain as true a balance as possible the laterals—really the fruiting wood—are left on the upper side of the lower, and on the under side of the upper branches.

No immunity from blight or disease can be claimed even for trees vigorous as these are, but it is certainly reduced to a minimum. Curled and blistered foliage, caused by cold cutting winds or the attacks of aphides, has been more or less prevalent every year during the earlier months when the growth is young and tender, and red spider comes later if the weather prove very hot and dry when the fruit is ripening. No harm can arise from such attacks if they are only met with promptitude and care. Plenty of clean water upon the foliage and branches, and screening from frost and the direct force of east winds, is all that a vigorous tree requires.

The mean monthly temperature of this part of Sussex will certainly bear favourable comparison with that of Greenwich, and after calmly reviewing the matter I am inclined to agree with Mr. Taylor that the climate is really not so bad as was supposed. There is, however, a peculiarity about it which adds materially to the difficulty of ripening the wood, which is that in the present month there is a mean decrease of 7° of temperature—there have been instances of its falling as much as 13° from that of September—and this decline is accompanied by very wet dull weather, the rainfall of October exceeding that of any other month.

I may add that the gardeners of this county cannot have much faith in the climate as being suitable for Peach-culture, for I have found Peach houses and glass casings to Peach walls in almost every garden that I have visited.—EDWARD LUCKHURST.

## PLANTS FOR CUT FLOWERS AND SPRAYS.

No. 5.

**GLADIOLUS.**—Invaluable for vases and for specimens in glasses are spikes of Gladioli, every bud in the spike developing when placed in water. Their season of flowering is a long one, commencing in June and continuing until the late autumn months. The earliest may be *G. blandus*, *G. communis*, vars. *albus*, *roseus*, and *ruber*; *G. byzantinus*, *G. Colvilli albus*, *G. cardinalis* and its variety *roseus*, and *G. insignis* are all of the early-flowering class, and succeed admirably planted in October in any rich light soil, well drained, doing remarkably well in peaty or vegetable soil, increasing amazingly, and once planted not needing any attention, never taking the "yellows" as the highly-bred varieties of both *ramosus* and *gandavensis*. They do well in the open spaces in the front lines of shrubberies, and planted half a dozen or more together, they being planted 4 inches deep, will give annually in June and July nice spikes of flowers for cutting. The clumps increase in size and beauty from year to year. *G. ramosus* in its many varieties is more tender by the continued improvement of the hybridist, and this section coming in after the *G. communis* and other kinds named should be planted extensively, for though the *ramosus* section have not the stateliness of the *gandavensis*, they are equally bright and varied in colour. Plant in November and again in February 4 inches deep, and mulch over the surface with about an inch thickness of partially decayed leaves or other refuse of a light protective description. Wet, however, is the great evil, and the ground should be well drained, and if grown in beds protection may be given from heavy rains and severe frost. The bulbs may be 6 inches apart and the rows 9 inches, which will be sufficient space for this section. A top-dressing of manure in spring, cow dung being best, will add to their vigour, applying it after the stems rise, and being careful to stake as the stems advance in growth, and applying liquid manure after the flower buds appear.

*G. gandavensis* hybrids.—These are magnificent for late summer and autumn, planting during the first mild weather in March 3 inches deep and a foot apart every way. The ground for them to be trenched and manured very liberally, mixing the manure with the soil, and in a thoroughly decomposed state by planting time. Planted after the middle of March, and at monthly intervals to the middle of May, we may look forward to a good stock of spikes of matchless beauty for cutting in late summer and autumn. The varieties are very numerous both of *gandavensis* and *ramosus*, so that I shall not pester your readers with names, which may be taken from the list at the price suited to each purchaser. For very late flowers plant in June with a certainty of a speedy loss of bulbs. Bulbs of the *ramosus* section, if potted in November, three in

a 6-inch and five in a 7-inch pot, an inch deep, and plunged in a cold pit, removing to a greenhouse when the spike rises, will flower six weeks earlier than those outdoors, and some being left in the cold pit will succeed them and continue the display until those in the open ground bloom. If very early bloom be wanted it is better to pot some of the *G. blandus*, *communis*, or other of the early-flowering sorts, in October; these gently brought forward after Christmas will flower in May or earlier. *Gandavensis* varieties are also grown in pots, but not for our purpose, except it be a late batch, put in in June and kept plunged in ashes outdoors and well supplied with water, giving them the shelter of a cold pit or cold house in autumn. Two parts medium-textured turfy loam, with a part old cow dung and a half part of sand, will grow Gladioli in pots perfectly, but I have a hankering after peat—sandy fibrous peat. All the species like it, and in it never, that I know, have the "yellows."

**PANCRATIUM SPECIOSUM** has large white fragrant flowers during the spring or early summer months, and is quite equal to the famous *Eucharis amazonica*, having usually eight flowers in a scape. *P. Caribæum* has also large white fragrant flowers, both being stove plants requiring abundant supplies of water when growing, and continued until the growth is complete or full-sized, and then gradually reducing, giving only sufficient to keep them from flagging, and not allowing them to be dry at any time. Good turfy loam three parts, one part each sandy peat, old cow dung, and silver sand with good drainage will grow the plants well.

*P. Cunninghamii* has campanulate white flowers about an inch wide, and for button-holes superior to the *Eucharis*. It requires a warm greenhouse, and the plants should be well watered during growth, and not dried-off when at rest.

*P. illyricum* and *P. maritum* have both white flowers, and are hardy in sheltered positions, and a little protection in severe weather. A well-drained soil is essential, and equally so is abundant watering during growth. Not the least charms of *Pancratiums* are the delicate green stripes which pervade their pearly white flowers, and their scent. They are easily cultivated and free-flowering, and are deserving of extended culture, especially *P. speciosum*, also *P. mexicanum* (notatum), which has often a dozen flowers of snowy whiteness on a scape, the flowers being very fragrant. It is a stove species, though both the two last-named will do in a warm greenhouse.

**AMARYLLIS** and **HIPPEASTRUM** are magnificent as cut flowers, but we confound the one genus with the other. The true *Amaryllis* is characterised by flowering before the leaves, and is as thoroughly deciduous as the extremely beautiful *Amaryllis Belladonna*, which is one of the most beautiful of hardy bulbs, and on which a very opportune and excellent article was given by "W." at page 183 of the present volume, to which the reader is referred for particulars of treatment. The *Belladonna* Lily is the true type of an *Amaryllis*, and would be immensely improved were it induced to produce its flowers and leaves simultaneously. There is no affinity between the *Hippeastrum* and *Amaryllis*, hence it has been suggested by some to gain foliage for the *Amaryllis* at the time of flowering by crossing with *Valloia*, but the hybridisation cannot be effected.

*Hippeastrums* in their original types are evergreen, of which none are more representative than the very beautiful *H. pardinum*, one of the many beautiful plants brought to notice through the Messrs. Veitch; but the *Hippeastrum* has been crossed this way and that, and so thoroughly subdued by a continued system of drying culture as to become every whit as leafless as the *Amaryllis* in the resting season, and in this respect at least the alteration has been of a retrogressive kind. *Hippeastrum* and *Amaryllis* are the most magnificent of all bulbous plants, their immense trumpet-shaped flowers being truly grand in a cut state. They flower usually during the early summer months, but may be retarded or forwarded by keeping cool and dry, or starting in bottom heat with a brisk heat and moist atmosphere.

*Hippeastrum pardinum* is a fine cream colour, closely dotted with crimson-red. It is strictly evergreen, and should not be dried-off; *H. equestris* major, orange and green star, is also a true type of *Hippeastrum*, the double form *H. equestris* being novel; *H. Alberti* flore-pleno is very double and a fine orange-scarlet; *H. cinnamomea*, rose, is sweet-scented; *H. Ackermannii*, and its variety *pulcherrima*, being really grand, having large crimson-scarlet flowers very finely marked; *Aulica platypetala* is red tipped with green with yellow stripe. This is one of the best for forcing, and may be had readily in winter by affording heat and moisture after

a period of rest; and of the same free-blooming character is *H. marginata* conspicua, and its variety *superba*, both with white grounds and crimson stripes, and are of the finest, especially for early flowering. The finest of all for early or winter blooming is *H. robustum*. *H. regina*, deep red, is fine from its orange and white marking; *reticulata striatifolia* is good either as a flowering plant or for its leaves, which have a clear white band down the centre, and these have a grand effect interspersed with *Amaryllis* blooms for the table, for no flower has given it so fine a setting as its own foliage. Prince of Orange, Graveana, crocea grandiflora, and Cleopatra are useful and much alike; but of late there has been some grand additions, and these have, of course, "fancy" values.

The above are all stove plants. They will succeed, it is true, if they are started in a hotbed and continued there until far advanced for flowering, and then removed to a warm greenhouse, or a house where forcing is carried on. A warm greenhouse is only another name for a cool stove. I am told the *H. vittata* and varieties may be grown planted at the foot of a south wall, protected with litter in severe weather. It would be interesting to know if this has been practised in England and where.

If dry pot the bulbs in fibrous yellow loam three parts, one part each leaf soil and old cow dung, and a sixth of sand, and good drainage. This may be done in January, and the pots should be placed in a light position without water until the bulbs begin to grow—the scapes appearing first or simultaneously with the leaves—water then should be gradually given, increasing the supply with the growth. If the pots are placed in a bottom heat of 70° to 75° it will facilitate the growth of roots, and is a desirable method of treating bulbs which have been dried. The temperature should not be less from fire heat than 55° at night and 60° day, and 15° rise from sun heat; but the usual stove temperature after January—i.e., 65° to 60° night, 70° to 75° day, and higher in bright weather is more suitable; in fact, stove treatment is necessary, and if this be not afforded start the plants in a hotbed, removing them to a warm greenhouse when advanced for flowering. After flowering keep them well but not overwatered, and in all their stages they require to be near the glass and have all the light practicable with moderate ventilation. In June, especially if the plants cannot be kept near the glass, they may, the flowering being over, be placed in a cold pit, and that will be a stove by early closing and admitting air judiciously. In this position the plants will be the better from gentle showers, and by the middle of August they will need maturing treatment, water to be given only to prevent flagging, removing early in September to shelves in the stove, where they will speedily mature. No water then to be given, the moisture of the house will be ample to prevent flagging of the foliage. If the leaves die-off, as the present race do, a light damping of the pots occasionally from a syringe will prevent loss of roots, and if these are maintained sound there is no need of bottom heat at starting; but if the roots are lost from overdrying the bottom heat is a necessity for speedy rooting and vigorous flowering. The most favourable time to repot is when the maximum of growth is reached, taking care not to break the ball, picking-out the soil from amongst the roots, removing the surface, and placing fresh soil at the bottom of the pots, the plants then may be returned, with some fresh soil all around, pressing it firmly. A good watering to follow the potting, and gentle sprinkling overhead two or three times a-day, with a close atmosphere, and slight shade if the weather be bright will enable the plants speedily to recover the potting, and plants so treated will give flowers very superior. Shade is not needed for these plants, except those of weak growth, which cannot stand the sun, and such should have slight shade, and a warmer and moister atmosphere. —G. ARNEY.

### CARRION FOR VINE BORDERS.

THE other morning my employer came to me and said, "We have a cow dead, and I want it buried in the Vine border. Is it not a good thing for the Vine roots? A gardener told me that it was, and that Vine roots would go half a mile to it." I gave him, as my reason for objecting, my opinion that Vine roots do not readily penetrate a mass of putrid matter, if they penetrate it at all, and that it is an unnatural element for Vine roots; but still, I added, "the place is yours, not mine, and I will obey your orders." "No," said he, "your reasoning is conclusive, and I give up my theory to your practice."

I know that years ago there was much said in some quarters in favour of carrion for Vines to luxuriate in, but I never believed in it, nor do I now, but I would ask whether you think I am right or wrong in the matter. I am open to conviction, and if you choose to lay the matter before the readers of "our Journal" I should esteem it a favour to have the opinion of any of our practical men through the medium of its columns, as Grape-growing is well to the front at the present time.—INQUIRER.

### GRAPES AT THE EDINBURGH SHOW.

I HAVE been very much interested in reading the discussion respecting the merits of the two large bunches of Grapes which were exhibited at the Edinburgh Show. Mr. Dickson's letter clears up matters considerably, and explains why his bunch appeared tarnished. It certainly does seem very strange that Mr. Dickson should have been excluded while so many others were allowed to witness the process of weighing; and the feelings of Mr. Dickson may more easily be imagined than described when he saw the bunch of Grapes which had cost him so many months of anxious care defeated almost beyond recognition, and that before the public had an opportunity of inspecting his production. I consider Mr. Dickson is entitled to the sympathy of all lovers of fair play.

I trust the suggestion of your able correspondent, "J. W.," in his description of Arkleton, that some token of respect for such distinguished ability would be fittingly bestowed upon the man who has accomplished such wonders in Grape-growing may not be allowed to lie dormant, but that a committee may be appointed to carry out the project, and to whom I will gladly give my mite.

With respect to Mr. Dickson's query, What constitutes a bunch of Grapes? my own opinion is that a bunch of Grapes must proceed from one stem, and that two or more stems proceeding from a Vine shoot, however close together, must be considered as two or more bunches of Grapes.—A. K.

As an outsider in the discussion going on of weighty Grapes you will, perhaps, allow me to suggest that in future it would be wise to give permission to exhibitors of weighty Grapes to assist and scrutinise at the weighing. If this were allowed, and a set time appointed for its performance with the Judges by the Secretary, much annoyance, heart-burnings, and misunderstanding would be prevented.—HENRY KNIGHT, Floors.

AFTER what has been stated it is incumbent on the managers of the late Show to state officially whether the Judges carefully examined the bunches before weighing them, and were cognisant of the particular formation of each bunch before they awarded the prize? If the awards were made after examination, and with a full knowledge of the state of each bunch, then the matter is settled so far as regards this Show. But if this examination was not made, and any peculiarities were from any cause overlooked, then it is beyond all doubt the duty of the Committee to thoroughly investigate the case. This may be unpleasant, but it is nevertheless a duty, and on that account they must do it, both for the honour of Edinburgh and in deference to the opinion of a world of Grape-growers. I write not as a partisan. I care not who obtains the prize, but I do care to know if the bunches of Grapes which have recently startled the world are really what we expect them to be—viz., fair single bunches, and not accidental monstrosities.

Mr. Dickson has plainly told us that Mr. Currer's bunch was "two bunches," and states that he holds testimony to that effect. I ask him to produce that testimony.—AN ENGLISH GRAPE-GROWER.

HAS not the time come when the question as to what is a bunch of Grapes should be authoritatively settled? Surely this should no longer be an undecided question, and yet it is a question—though apparently simple—not easy to answer. One good Grape-grower and judge says, "A bunch to be beyond dispute (and this he considers a vital point) should have a smooth and perfectly round stem, showing no signs of a cicatrix such as the union of two bunches might be expected to show, whether caused naturally or artificially." Another says, "Provided a bunch comes from a single eye, no matter what the form of its stem, it is one bunch and one only." Now which of these two definitions is right? There is this to be said on the part of the former—that it cannot be wrong. As is well known, a cane will burst two eyes, and the stems and

bunches become naturally united, forming a fasciated stem and bunch. In that case is it more than one bunch? Thus simple as the question at first sight may appear, it is when examined rather subtle, but none the less for that should it rest undetermined.

Huge bunches of Grapes seem to be yearly increasing in size, and I submit, therefore, that the simple question of what constitutes one bunch of Grapes should be finally and authoritatively settled. I have not either the slightest interest in the bunches lately exhibited, or the remotest feeling as to which is successful, but I should, in common with those of my craft generally, like to know what is the standard for judging "a bunch of Grapes."—A NORTH-OF-ENGLAND GARDENER.

Most of the Grape-growers in the country are anxiously waiting your version of what constitutes a bunch of Grapes. I myself, an old Grape-grower, for one, will be much disappointed if I find your version to be that we are to pass a bunch as one bunch with two separate fruit stems from the main or side shoot. I have been acting as judge this season at a show of some pretence, where a bunch was shown for the heavy prize having two fruit stems from the main rod or side shoot somewhat ingeniously worked together, but we did not hesitate in disqualifying the said bunch. Anxiously waiting your version.—M. SUTHERLAND.

[We shall be glad to hear from our readers their definition of a bunch of Grapes.—EDS.]

I AM very much disappointed at "D. R." not answering my questions. From the fact of his being present at the weighing and interesting himself so much in the proceedings, he must have known whether the Judges were present, and, if so, if they inspected the Eskbank Grapes; for it is very important that it should be known whether it was an oversight on their part, or that they accepted it as a *bond fide* bunch.

In your issue of the 14th inst. "A GRAPE-GROWER" says, "It is not too much, I think, to ask Mr. Dickson for the names of the gentlemen who are able to corroborate his statement; it would strengthen his case, and do them no harm whatever." I most cordially comply with his request, and furnish the letters which I have received from these gentlemen, and leave the public to draw their own conclusions.—JAMES DICKSON.

"My answer to yours of the 29th ult., 'What I consider constitutes one bunch of Grapes?' is, that it should all come from one eye, the same as your large bunch that was exhibited in Edinburgh, and not an inch or two apart, as the fruit stems of Mr. Currer's bunch were. To have a perfect bunch of Grapes the bunch should hang by one stem. I corroborate every word you say in reply to 'AN ENGLISH GRAPE-GROWER.' I was staging my fruit in the room when your bunch came in, and I can affirm that the berries were neither rubbed nor bruised, and no bunch could have carried better. I went and looked at the bunch soon after it came in.—ALEX. INGRAM, *The Gardens, Alnwick Castle.*"

"In reply to yours of the 27th ult. After seeing the Eskbank bunch it was what I considered to be two bunches of Grapes, or what I always understood to constitute two distinct bunches of Grapes. They were, as far as I can judge, from 2½ to 3 inches apart. I could have shown some splendid bunches of Black Hamburg, but could not owing to the fruit stems being half an inch apart.—P. STEWART, *The Glen Gardens.*"

"In reply to your note of this morning (Sept. 25) regarding Mr. Currer's large bunch of Grapes, I beg to say that I consider the prize fairly yours. Mr. Currer's exhibit was a grand bit of Grape-growing, but at the same time you cannot fairly call it one bunch. I have always understood one bunch to mean one stem from the wood, however short, or even two if they fairly split at the union with the wood. But Mr. Currer's had quite 1½ inch of clear space between the two stems; therefore I consider them two distinct bunches, and I think, for the sake of those who exhibit, it ought to be clearly understood that one bunch of Grapes should hang by one stem.—JAMES LOUDON, *The Quinta, Chirk, Ruabon.*"

"Yours letter duly to hand, and I must own I cannot blame you for re-opening the question, 'What constitutes one bunch of Grapes?' My old friend Loudon of The Quinta and myself the moment we saw it (Mr. Currer's bunch) called it a 'twin.' This is the first time that I ever saw a twin beat a dead honest one bunch.—WILLIAM JONES, *Gardener to Marquis of Londonderry, The Gardens, Wyngard Park, Stockton-on-Tees.*"

"I AM in receipt of yours of the 4th inst. I certainly did examine the Eskbank bunch of Grapes, and there was decidedly a clear space of an inch or two between the fruit stems, which in my opinion made two bunches of Grapes. What I consider one bunch of Grapes should come direct from the shoot with one stem. Any more stems, of course, are so many more bunches.—I. THOMSON, *Edinburgh.*"

"Yours of yesterday (Sept. 29) is to hand. I don't think any Grape-grower in the kingdom will for one moment dispute your opinion as to what constitutes one bunch of Grapes, that 'there should be but one fruit stem from the shoot.' The other morning in the Music Hall when you asked me to look at Mr. Currer's bunch I was prevented by the policeman from inspecting it. I shall feel deeply interested to know how the matter will end, and trust justice will have its proper course.—GEO. JOHNSTON, *Glamis Gardens.*"

## NEW JAPAN ROSE, BEAUTY OF GLAZENWOOD.

A few years ago we looked upon the list of forthcoming new Roses with much greater interest than at the present day, for so many new varieties are annually poured into the market, which prove mere costly rubbish, that we have had a cooling-down. Had Mr. Smith's illustration of Beauty of Glazenwood, in the "Floral Magazine," appeared in those old times, it would have created a tremendous sensation, and, cautious as we are grown, this real novelty cannot fail to awaken much interest throughout the Rose world. A Rose of golden-yellow, striped and flaked with scarlet or vermillion, sounds like a dream or a fairy tale. It is, nevertheless, a reality, attested by Mr. Smith's brilliant plate, in which Mr. Woodthorpe considers full justice is not done to the richness of colouring of the Rose itself.

When I was in Essex, in July, I had the pleasure of seeing fine healthy trees of this remarkable Rose, but I was a little too late for the flowers. Some blooms had just been sent to Mr. Smith for making his illustration, which may have been seen already by some of your readers. I am glad to testify to the very vigorous growth and hardy character of this Rose. The heads of standards of it consist of long graceful shoots from 4 to 6 feet in length, which were last winter perfectly uninjured even to the tips, though quite unprotected.

Beauty of Glazenwood is a summer-blooming variety, and will make a beautiful climber or an equally fine standard, flowering as it does from every eye on its long pendulous shoots. Mr. Woodthorpe describes it as strikingly lovely in the bud state. It is like Madame Falcot in its yellow ground, while the vermillion flakes on the petals resemble "the colouration of a Tulip," and it has also a delicate fragrance.

It will certainly prove an important and charming addition to our already rich array of Roses, and be most valuable in hybridisation, on account of its peculiar colouring and distinctness.—HENRY CURTIS, *Devon Rosery, Torquay.*

## THE LEEDS NATURALISTS' FIELD CLUB AND SCIENTIFIC ASSOCIATION.

120TH MEETING, SEPTEMBER 15.

MR. JAMES ABBOTT exhibited a number of interesting plants collected in the West Riding, including *Potentilla norvegica*, which grows abundantly on the banks of the Leeds and Liverpool Canal between Armley and Kirkstall, and appears to have been thoroughly naturalised. It was first gathered about 1880 by Mr. Wm. Kirkley, but not satisfactorily determined at the time. In 1888 it was found, also apparently native, in Burwell Fen, Cambridgeshire, by Mr. G. S. Gibson, and recorded by him in the "Journal of Botany" for that year (vol. vi., p. 802; also see Babington's "Manual," seventh edition). In 1874 Mr. Abbott noticed it in great abundance, and this year it was sent to Kew to name, when it turned out to be a Scandinavian form, though in what manner it reached the Leeds district is as yet unaccounted for. Mr. Charles Hobkirk reports that in 1873 he found it on the banks of the canal near Huddersfield.—W. D. B.

STRAWBERRIES AT NOTTINGHAM.—On looking through the flower market last Saturday (October 16th) a great crowd seemed to be gathered round one notable stall. I soon saw the cause—viz., a basket of very fine Strawberries (*Vicomtesse Hérécart de Thury*) was there on view, equal in colour and fair for size. They were gathered from the open ground on the 15th from established plants that had borne heavily during the season, and had received no extra care or attention. They

were grown in the Strawberry gardens of Mr. Joseph Lamb, Burton Joyce, near Nottingham, the same person who was awarded the two first and one second prize at the great exhibition held in the Arboretum during the summer.—S. P.

### THE OLEANDER.

WHEN laden with their noble tresses of beautiful rose-coloured flowers these plants are ever to be admired; but under their beauty danger lurks, for the plant contains one of the most virulent of poisons. This applies more particularly to *Nerium Oleander*, although the double-blossomed species, *N. odorum* plenum, so common in the conservatories of England and on the terraces of continental gardens, is by no means innocuous. It is well, therefore, that in appreciating the undoubted beauty of this family of plants that we should be cognisant also of their poisonous nature. They are plants to be enjoyed for their beauty, but must not be thoughtlessly played with.

In proof of the poisonous nature of the family, it is on record that some soldiers during the Peninsular War collected wood of the Oleander and of it made skewers for their meat, and the result was that of twelve who partook of the meat seven died, and the remainder suffered acutely. It is further recorded that in order to facilitate the removal of the bark Dr. Roxburgh put some young shoots into a fishpond, and found the poison so extreme as to kill nearly all the fish. It is also known that when the trees are growing in full luxuriance in their native habitats that there is danger even in sleeping beneath their shade, on account of their noxious exhalations. Thus the plant is treacherous in its nature, for its beauty is but a garb to hide its hidden powers of evil. There is, however, some consolation in the fact that the poisonous nature of the plant is not so great when grown under artificial cultivation as when flourishing in its natural wild luxuriance.

Therefore with ordinary care *Neriums* may be cultivated for the beauty of their blossoms; but no child should be permitted to playfully eat its flowers, nor gardener thoughtlessly make a toothpick of its shoots.

The double varieties of *Nerium* are exceedingly ornamental conservatory plants, and their culture is extremely simple. Young shoots will readily strike at any period in brisk heat, and older wood will emit roots in profusion if the shoots are inserted in phials of water. In growing the plants to a flowering state too much water cannot be given to the roots, and scarcely too much heat and sun can be afforded to the foliage. The points to aim at are an early season of growth in a light and well-heated structure, a dry atmosphere to ripen the wood, and a rest in winter by withholding water. The shoots that are made one season flower the next, and the plants if properly prepared will force well. They may after blooming be cut down and shaken out, as is practised with *Pelargoniums*, which will keep them dwarf; they will then have a season of growth, and will flower grandly the season following. Large plants will, however, flower every year on the preceding year's shoots, but they attain a straggling habit if not pruned occasionally.

Cuttings if struck in the spring, planted out in a hot place to make their growth in the summer, and potted during the

autumn, will often flower the year following, and large plants are produced in a less time by planting-out than can be produced by pot culture.—J.

### STRAWBERRY CULTURE.

THE few lines inserted on page 275 of "our Journal" sufficiently explained my motive, which certainly was not to enter into any controversy with Mr. Lovel, whose name had never attracted my observation till August 26th, and I should not reply thereto if his subsequent communication inserted on page 332 had not a tendency to mislead. I do not go two or three years without tasting fruit, but I take about half a score from each plant the first year, and they are as fine as any I obtain; that is all the plants are allowed to bear. I take my runners from old plants reserved for the purpose and in pans or pots, which I find is the only way to obtain really good plants. I do not doubt what Dr. Roden has stated,

but he is one I believe of the few who retain their plants many years; his experience must always carry great weight, and for his contributions to "our Journal" all Strawberry-growers are indebted; but the statement made by your correspondent of what Dr. Roden has done is not what we differ on.

I can quite comprehend how it is possible to grow 1 lb. of fruit per plant the first season after planting. Your correspondent should not have curtailed the sentence, but added, "on plants planted in September, grown in very light soil, without any manure added at the time of planting, and twice transplanted." Another omission, I take it, occurs after the following sentence:—"From British Queen, Dr. Hogg, President, and others I could pull thirty Strawberries to weigh 1 lb." Would he add from one-year plants planted last September and without manure? All Strawberry-growers know that British Queen and all the race require strong ferruginous soil and well manured to bring them

to perfection, and at page 182 your correspondent alludes to President as one of the kinds that do not fruit well the first year.

I can assure your correspondent that I have very carefully read his communication at page 242, and quote therefrom:—"I strike my runners in each alternate row of first-year's plants, gathering the fruit from every other row." If this does not mean that every other row is set aside to take runners from what can it mean? But his explanation makes his practice, in my opinion, far worse, for he states that he takes from every plant four to six runners and 1 lb. of fruit too, thus weakening his plants so much in their first year's growth as to render them worthless, for to take five plants from every 15 inches longitudinally must remove nearly all the soil on one side of the plant. The point is not whether 1 lb. of fruit per plant can be produced the first year after planting—I know that can be done, but before I believe it can be done under the circumstances stated by your correspondent I must have the authority of such men as "D., Deal," "C. P. P.," Rev. W. F. Radclyffe, and Mr. Douglas, or men of that stamp, to whose opinion one can defer, and on whose judgment one can rely.

As an amateur of more than twenty years' experience, who has studied and practically tested the opinions of such as I

Fig. 76.—THE OLEANDER.

have named and other contributors to "our Journal," and who has not neglected an opportunity of inspecting in all parts of the country the practice of others, I can truly say that I never heard or read of the British Queen or any of her race doing well on very light soil before, but, on the contrary, have both read and heard of the sort being changed for others more suitable to the soil, and I hope to have my opinion confirmed or otherwise by such cultivators as I have named.—AN OLD SUBSCRIBER.

### ROYAL HORTICULTURAL SOCIETY'S SHOWS FOR 1878.

THE Council have decided to hold five great shows besides the usual fortnightly meetings in 1878. The first or Spring Show will be held on the 16th of March, the May Show on May 8th, the June Show on the 7th and 8th of June, the July on the 19th and 20th of July, and the Great Fruit Show on the 8th of November. A liberal schedule is in preparation, and will shortly be ready for circulation.

### GLADIOLI—DEGENERACY OR DISEASE.

I ACCEPT the challenge Mr. Douglas has thrown down, and maintain that the cause of failure in the Gladiolus does not arise from degeneracy, but from a disease which we cannot master, but which seems to me to bear a remarkable analogy in its effects to that which infects the Potato. Let me first define what we mean, lest it be simply a war of words. I understand by degeneracy a weakening of the constitution, by which the plant becomes incapable of flowering with its former vigour, and so becomes worthless to its possessor. By disease I understand some affection of the tissues of the plant, by which the oorm becomes so seriously influenced that it is unable to maintain life at all, and so perishes. In some cases the disease may not absolutely kill the plant, but it very rarely is able to grow again.

Mr. Douglas holds that his Gladiolus bulbs are affected by the former complaint, and adds that if I did not import each year from France I could not maintain my collection. He may be surprised to hear that, with the exception of the new varieties, I import very few bulbs, and that some of my finest spikes this year were from English-grown oorms. But independently of my own experience I can give that of another grower who is, I believe, by far the largest amateur cultivator of the Gladiolus in England. He has, to my certain knowledge, not imported one single bulb from France for the last ten years except the novelties of each year, and yet he has every year from eight hundred to a thousand surplus bulbs. Nor are these poor bulbs: they pass, many of them, into the hands of one of our most respected seedsmen, and not only are they satisfied with the bulbs, but their customers invariably speak of them as satisfactory.

I may add that one or two of the spikes of Meyerbeer which I showed this year were from his bulbs.—D., Deal.

### POTATOES.

As the time (November 10th) is drawing nigh for the Potato competition, a few remarks from one who is not a competitor, but who feels himself interested in the forthcoming struggle, may perhaps find acceptance. The competition will bring out many points of culture that will be useful to the raisers of new sorts in the way of propagation; but according to the arrangements some unpleasantness may arise. The crops I think ought to be taken up in the presence of Messrs. Hooper & Co.'s agent and weighed on the spot, and that weight to be the standing point, no matter what is lost afterwards by disease; whereas this season the disease is so prevalent that some of the competitors will lose two-thirds of their crop before the time to send them in for competition, and this will happen in the case of those that have the most weight and have been produced with high cultivation. Of course when the crops are lifted and weighed they will be placed in the best position at command to keep them until the time to send them in. Now what is to prevent those competitors who have a surplus stock in hand from picking out the diseased tubers and replacing them with sound tubers? Not that I think any honourable person would do it, but it is an old saying and a true one that there is "more got by scheming than by hard working."

There will be some great weights from 1 lb. of seed, in fact

one has already appeared in the Journal; but at the same time I cannot see that any practical purpose will be gained by it, as the system by which they are produced will never do for ordinary cropping. The weights will also lead many people astray unless they are well acquainted with each variety and the mode of growth which has been adopted. The American varieties will stand cutting into the smallest sets possible, and they will grow, soil and season being favourable, into heavy crops; but I think that is no proof of real value.

I should like to see prizes given for some of our best English varieties, which are not so liable to the disease as the American varieties, but they will not stand cutting nearly so small as the Yankees; and 1 lb. of English seed would not produce more than half the weight that the same quantity of American seed would, and yet the English variety may be more really useful under ordinary cultivation.—H.

### A VISIT TO POTHOLM,

THE RESIDENCE OF JOSEPH TAYLOR, ESQ.

WHEN in the picturesque district of Eskdale, besides my visit to the small garden of Arkleton and its great Grapes, I was induced by the owner of Burnfoot to inspect the garden of Mr. Taylor, whose residence is ensconced amongst the heath-clad hills, and is two or three miles distant from the flourishing town of Langholm. I was rewarded by witnessing some good gardening, the Grape-growing especially being of a superior order. This garden was then under the charge of Mr. Bole, who is now gardener to Lady Crossley at Somerleyton, Suffolk. Potholm is not a large garden; it was newly made by the owner, and under the able management of his gardener it was more than ordinarily productive. As the Grapes were the chief feature of the place, almost rivaling those of Arkleton, and as I am, by the courtesy of Mr. Bole, able to supply instructive matter concerning them, I will give them prominence in this brief notice. I have said they almost rivalled those of Arkleton, but I believe that on more than one occasion the Potholm Grapes have had the post of honour when in competition with the produce of the above renowned vineries at the local exhibitions. Grapes, then, that have done so much as have these must have a history worth knowing.

The vineries were finished in May, 1869, and on the 28th of the same month the last of the Vines were planted. The site of the garden was styled The Orchard, in reality a waste which had been occupied for at least a hundred years by Apple, Pear, and Plum trees, which had grown to giant proportions, with an undergrowth of Nettles fully 6 feet high, and what was not covered with Nettles was with Docks, Ranunculus, &c. But what has this to do with Vines? I will show that it has, or had, much to do with them, and played an important part in the success which has attended their culture. All this confusion had to be cleared away, the trees were uprooted, and their branches carried into a heap; the whole surface was pared off with the spade—grass, weeds, top soil, &c., and when all was ready the heap was fired. Some idea of the extent of the fire may be gathered from the fact that it burned for eight weeks. Here, then, is the secret of these fine Grapes—charred soil, ashes, and charcoal. The whole of this was incorporated into the soil forming the Vine and Peach borders. The old mansion house had also been pulled down; the old plaster, lime rubbish, &c., were also used. The soil was taken from a place where sheep had been folded, shorn, &c., from time immemorial, the turf being cut just as deep as the roots of the grass would lift. This was made up into a heap mixed with inch bones, the lime rubbish, and the residue of the great fire; and the whole lay in that state for about six weeks before using. The bottom of the borders were efficiently drained with about 1 foot of stones, brickbats, and the roughest of the refuse from old buildings, then turves green side down were laid over the whole. The soil was put in about 3 feet deep.

The Vines were planted and watered with tepid water on the day mentioned, and by October in the same year they had canes over 30 feet long, twice stopped, and the wood well ripened. They were pruned in November and started in March. One bunch was taken off each, the Syrian bunch weighing 7 lbs. In 1871 a bunch of the Syrian weighed 14 lbs., and in 1872 a bunch was cut weighing over 16 lbs., and in 1873 three bunches from one Vine weighed over 40 lbs. At that time the Vine, four years old, measured at 1 foot from the soil 6 inches in circumference, the young wood being 2½ inches in circumference. The other Vines consist of the old standard

varieties, and have succeeded in a manner that should satisfy the most fastidious. They were dropped as follows:—In 1870 they carried one bunch, in 1871 three bunches, in 1872 six bunches, and in 1873 and subsequently eight to ten bunches each. The Vines look as well now as ever they did, the average growth of the Black Hamburg measuring 2½ inches in circumference. The only covering which is given the borders during winter is a quantity of stable manure, and all the rain that falls on them is permitted to enter them, and that is something very considerable, averaging 5 feet a year.

Such is the history of these Vines. It is worth giving from its simplicity and for the soundness of the practice which it embodies. The practice which has produced such fine Grapes in Eskdale will, if adopted, produce them similarly fine in other places.

It is not necessary to dwell on the excellent plant culture at Potholm, or on the fine collections of Pentstemons, Phloxes, Dahlias, &c., growing in the grounds, but a passing glance may be made on the collection of hardy Heaths, many of which were charmingly ornamental at the time of my visit. These chastely beautiful hardy plants are worthy of extended cultivation. They will grow in almost any soil, providing it does not contain lime. These were luxuriating in a mixture of peat, leaf mould, and loam. I saw no collection of plants in Scotland more distinctly ornamental than Mr. Taylor's hardy Heaths at Potholm.

Mr. Taylor has, by the liberal means afforded in perfecting his own garden, done much for the horticulture of the district; and it is gratifying to find that Mr. Bole on his departure from Eskdale was presented by the inhabitants of the district with a handsome Fitzroy barometer and a purse of thirty sovereigns as a token of their estimation of his character as a man and his skill as a gardener.—J. W.

### OUR BORDER FLOWERS—ERINUS.

THIS is a small group of early spring and summer-flowering plants belonging to the Alpines. These plants will succeed in many situations, but they are chiefly recommended for rockeries. They are also adapted for edging purposes in the spring garden or elsewhere. When once established there is little fear of them becoming scarce. They grow well in a mixture of loam, leaf mould, and coarse grit. There are a few kinds enumerated, but they are all much the same in habit and appearance, the different colours being the distinguishing feature. When grown together the different shades of colour have a very pleasing effect, varying from rosy purple to white.

*Erinus alpinus* is most frequently met with. It is said to be from Switzerland, and admitted to our flora as a naturalised subject. *Erinus alpinus roseus* is an acquisition; its flowers being large and approaching rose colour, makes it very desirable. *Erinus hirsutus*, said to be from the Pyrenees, is but seldom seen. Perhaps the diminutive stature of these plants causes them to be overlooked, or it may be they are not sufficiently known to attract attention. I know a place by the side of a river where *Erinus alpinus* can be seen to perfection growing among the stones and sand. Whether the seeds had been washed there by the stream, or they had been purposely sown, I had no means of ascertaining.

Perhaps the time is coming when these partly-forgotten plants will be better cared for; they ought to be much more cultivated than they are at present.—VERITAS.

**THE GRAPE CURE.**—Amongst the most agreeable hygienic processes extant, says the *Pall Mall Gazette*, must be reckoned the Grape cure, for which this is the season. There are on the Continent numerous establishments devoted to the use of the remedy; two in France—Aigle in Savoy and Celles-les-Bains in the Ardèche; three at least in Switzerland—Vevy, Vevey, Montreux; and many in Germany, Austria, the Tyrol, and Hungary. The juice of the Grape containing, according to a medical authority, 25 per cent. of its weight in active agents—glucose, tartaric acid; potash, chalk, soda, oxide of iron, and manganese in combination with sulphuric acid, phosphoric acid, &c.—there is some reason for comparing this "organic mineral water," as it has been called, with the inorganic, the curative powers of which are so universally recognised, and for expecting similar results from it. The cure is very simple. It consists in eating an immense quantity of Grapes, the thin-skinned sweet white varieties being best for

the purpose. The patient takes but little ordinary food, and is required to eat 3 or 4 lbs. of the fruit a-day just at first, the quantity being gradually increased to 8, 10, and even 12 lbs. of Grapes. This is, if possible, to be eaten in the open air, in the vineyard whence the supply is derived—an arrangement which, no doubt, greatly conduces to the efficiency of the cure. It is frequently undertaken in their private practice by French physicians, who possess the material for it in the incomparable Chasselas, of which such quantities are now selling in Paris.

### LUCOMBE, PINCE, & CO.'S NURSERY, EXETER.

ENGLAND is pre-eminently the country of stately trees and picturesque gardens; but in no part of our country do we meet with a more grand array of natural beauties, or a more happy application of the resources of art to enhance their effect, than in the county of Devon. The stranger visiting Exeter will find excellent hotel comfort; and he will naturally desire to see something of the town—the grand cathedral, the public walks and pleasure grounds, and the scenery of the neighbourhood. Being a gardener I made my way to the nursery of Messrs. Lucombe, Pince, & Co., which I will now endeavour to describe. This nursery was established in the year 1720 by William Lucombe, the raiser of the Lucombe Oak and many other choice trees, and has long been renowned for the excellence of its productions; and judging from the skill and enterprise at present being bestowed upon it by Dr. Woodman, who has assumed the administration of its affairs, its reputation is likely to be sustained.

On entering the gates the visitor cannot fail to admire a fine specimen of the Lucombe Oak. This is the original plant, and close by it stands the Cork Oak (*Quercus suber*), making a handsome pair. Two large plants of Ford's Oak (*Quercus Fordii*), raised at the establishment by old Mr. Pince's foreman, Mr. Ford, also attract attention. They are two noble objects, being trained as pyramids, and are unsurpassed in beauty.

The show house is our next object of interest. This superb conservatory is enriched with a profusion of beautiful plants, shrubs, evergreens, Ferns, and flowers arranged with great taste. Among the noted specialities were *Colusées* The Shah and Lady Burrell, and *Amaranthus salicifolius*. These plants were sent out with glowing characters, but we seldom hear a good word spoken of them, yet here they hold a prominent position, and are unsurpassed in richness of colour and vigorous growth.

Worthy of notice also is the *Camelia* house, which is more than 200 feet long by 80 feet in width. Some magnificent specimens are planted out in the borders, and seem to luxuriate in all their natural beauty, and form a perfect grove. Close to the termination of this house there is a rock garden most artistically arranged. The visitor enters apparently natural openings formed in natural rock, which is covered with a drapery of rare, curious, and beautiful rock plants and Ferns. Jasmines, Roses, Honeysuckles, and other twining plants festoon themselves over the rugged parts, and feathery forms fringe the bare blocks of stone, imparting an agreeable effect to the many secluded nooks and pleasant retreats.

We now pass to the stove plants. There are several large houses devoted to their culture, in which there are some very fine specimens. The clean and healthy appearance of these plants at once shows that skill is employed in their growth, and which reflects credit on Mr. Cole, the plant foreman, a member of the well-known Manchester family of plant-growers. I shall only particularise a few of the large plants in the specimen houses.

Here are tree Ferns and Palms, noble Bananas, and *Cyclophyllums*; handsome *Alocasias* Lowii, *Veitchii*, *zebrina*, *Jenningii*. *Orotans* are also in fine condition, the following being remarkably elegant, and ought to have a place in every collection—*Orotan variegata*, *C. Youngii*, *C. Veitchii*, *C. Johannii*, *C. lacteum*, and *C. Weismannii*. *Dracenas* are equally fine, the most distinct and ornamental being *D. congesta*, *D. imperialis*, *D. splendens*, *D. Fraserii*, *D. regina*, and *D. Mooreana*. Of *Marantas* I noticed a rich collection; *M. illustris*, *M. Lindenii*, *M. zebrina*, *M. roseo-picta*, *M. regalis*, and *M. Veitchii* are the best of this charming genus. Amongst flowering plants I observed *Eucharis amazonica*, with hundreds of white flowers, emitting a delightful fragrance. *Dipladenia amœna* was quite a blaze of flowers, as also were *D. crassinoda* and *D. insignis*. The *Ixoras* looked pictures of health, flowering freely; *I. Collei*, *I. crocata*, *I. Dixiana*, *I. javanica*, *I. salicifolia*, and *I. Williamsii* were all in admirable condition.

Many houses are devoted to the culture of Heaths, New Holland plants, Geraniums, Ferns, and Orchids. Most of the houses are 180 feet long. Grapes and Peaches are largely grown here, the Grapes being very fine, especially Mrs. Pince's Black Muscat, which continues to be a great favourite. The propagating department is a remarkable feature in this establishment. The houses are the best constructed of the kind in the country, and it is surprising how tens of thousands of plants are produced here in a short time.

It is now time to pass on to the outdoor department, which after all is the chief glory of the establishment. The grounds are about sixty acres in extent. Of ornamental trees, shrubs, fruit, &c., there are great collections. Many of them are of great beauty, and as yet not in common use. I noticed many hybrids comparatively new. Hybridising has long been carried on here with remarkable success, many new plants having been thus produced. The Conifer Walk is a quarter of a mile in length and intersects the nursery. In this department are plants of considerable size and great beauty, popular kinds, which I need not enumerate. On the left of this walk is the Winter Garden, planted also with Conifers and evergreens. The Irish Yew and standard Portugal Laurel are exceptionally fine and symmetrical. The variegated Hollies, both globular and pyramidal, are also striking objects. Opposite this is the Italian Garden, a perfect gem of its kind. The Irish Yews and Laurels with the vases give this garden a most exotic appearance, and the general beauty is greatly enhanced during the summer months by an extensive display of bedding and subtropical plants. I noticed here two new plants—one *Begonia Woodmanii*, a very fine variety, flowering well outdoors; the other a Geranium named *Bold Brook Pet*, a dwarf variety with large trusses of orange-scarlet flowers. For the removing and transplanting of large trees Barron's tree-moving machine is employed. It will carry eight tons and upwards, and Dr. Woodman said there is very little risk in removing them of that weight; and to substantiate his testimony he drove me to Exminster, a distance of three miles, where they have recently formed a new nursery, and where large trees have been planted and are flourishing well.

The nursery throughout is in a high state of keeping, and an inspection of the grounds and plant houses affords both enjoyment and instruction.—N. COLE, *Kensington Palace*.

#### HERBACEOUS PLANTS FOR BEDDING.

Among notices to correspondents in our Journal information is requested about a hardy herbaceous plant for bedding to flower at the same time as Geraniums. I have used effectively *Centranthus ruber*. There are three colours or varieties of this plant—red, crimson, and white, and when contrasted together or in separate colours they are very effective. By careful culture the plants may be had in bloom through the summer and often into early winter. To have a continuous bloom they require to be thinned and stopped to produce successional growths.

*Geranium sanguineum* is a plant that continues long in bloom. With careful thinning the shoots and stopping them the blooming season may be prolonged. *Crucianella stylosa* is a continuous-blooming plant, and might answer for the purpose named. It should have poor soil and be kept as dry as possible, otherwise it is a rampant-growing plant. *Delphinium Belladonna*, with careful stopping and pegging-down in good soil, is a very useful plant for bedding, and may be kept in bloom a long time. *Nepeta violacea* flowers a long time, and by careful thinning of the shoots gives a succession of bloom till autumn. *Dialytra spectabilis* is a fine plant for bedding in good soil, and by thinning the shoots it blooms a long time and is always prized for cut flowers. *Oenothera macrocarpa* and others might be named.—M. H.

#### EXTRACT FROM THE REPORT OF THE BRISBANE BOTANIC GARDEN, QUEENSLAND.

To illustrate the capabilities of the Queensland climate, it may be mentioned that the several varieties of the Mango plant, introduced principally from the far apart latitudes of Java, the West Indies, and Bombay, have yielded during this season more abundantly than heretofore; and this notwithstanding the unfavourable weather which characterised the earlier period of the season, upon the state of which the Mango is supposed to be mainly dependant in its fruiting. All the

plants are yet quite young—some having been propagated in these grounds, others imported in an infant state. There are three varieties from Java—the Sangier, the Gumpoh, and Dagiang. The fruit of all these plants is mellow and grateful to the palate, and invariably elicits high encomiums from those whose experience well qualifies them to form a judgment. These last mentioned are considered fully equal in flavour to the far-famed Mango of Bombay, of which these gardens contain three varieties—viz., the Strawberry, the Alphonse, and the Go. A Mango seed forwarded some years since from the West Indies has been successfully propagated, and plants of it distributed to some of the residents of Brisbane. A specimen of this season's fruit from one of these plants turned the scale at 26 ozs.

The following is a list of the principal plants that have flowered or borne fruit during the past year:—*Rhopala corcovadensis*, *Rhododendron virginialis*, *Pandanus utilis*, *Pandanus latifolius*, *Pandanus pygmaeus*, *Oreodoxa oleracea* (twelve years old), *Anthurium Scherzerianum*, *Philodendron Lindenianum*, *Strelitzia Nicotii*, *Maranta grandis*, *Achris sapota* (*Sopadilla Plum*), *Passiflora macrocarpa* (fruit 8 lbs. weight), *Lilium Wallichianum*.

**COFFEA ARABICA (Coffee).**—Attention has been called to this plant in consequence of a despatch to His Excellency the Governor from the Secretary of State for the Colonies, Lord Carnarvon, as to the Coffee-leaf disease in Ceylon. The Coffee plant in Ceylon is suffering great ravages from a well-defined species of fungus, *Hemileia vastatrix*, which belongs to a class of most minute parasitic plants, which include the oidium of the Vine and the peronospora of the Potato. This disease has for some time past been causing great anxiety and consternation amongst the planters there, as well as in some other parts of the world where it has appeared. It is satisfactory to find that no trace of this disease has as yet been found in Queensland, neither do I think, if care is taken, is it likely to take root here. In my report on this matter to His Excellency I went fully into the position and prospects of coffee cultivation in this colony, and have only now to remark that there is a fine field in the northern districts for the profitable investment of capital in the cultivation of this great commercial staple. Thousands of acres of suitable land are to be found from the Herbert River to the Endeavour River, all along the north-east coast, and extending from ten to thirty miles inland. In this district the branches of the tree grow very robust and horizontal, while it begins to bear fruit about the third year, producing very shortly thereafter 3 lbs. of berries per tree per annum. The plant flourishes, however, in all parts of the colony, although it is not so productive in the south, and takes longer time to come to maturity. I have every hope that on the publication of my report in England the attention of capitalists and planters will be directed to this colony, when it is known that the plant has found such a congenial habitation in northern Queensland, where there appears also to be every prospect of now obtaining a cheap, though inferior, class of labour; and especially when it is found that the plant is not subject to the ravages of this most destructive fungus. I would consequently call the attention of the Government to the great care necessary, at present, in permitting Coffee plants from being imported into the colony from countries affected with the disease; and I would suggest that, until the cause and origin of the disease is fully diagnosed, only seeds and plants be permitted to be imported from those countries where the disease does not exist. His Excellency has forwarded me a copy of the correspondence upon "the Coffee-leaf disease," which can be consulted, in the Botanical Library, by persons interested.

**CHOCOLATE, OR COCOA (Theobroma Cacao).**—This is another plant that could also be cultivated with great success in the same northern districts as coffee, and would form a most profitable and lucrative investment for capital, as there is an extensive market all over the world for its consumption. It is a plant which can be cultivated with much less trouble and expense for labour than coffee, being a tree of larger dimensions; it requires, however, to be planted more openly, but during the period the trees are taking to arrive at maturity the distance between the rows in the plantation could be turned to profitable account by the raising of such plants as Ginger, Arrowroot, Cassava, Indigo, &c. The trees take from four to six years to come to maturity, but thereafter they require very little labour or attention except to gather the fruit, for the Cocoa crop may be said to last throughout the whole year, although there are three principal gatherings of

the fruit annually. A Cocoa plantation once properly established is a rich possession to its owner; it is therefore to be hoped that some enterprising capitalist may consider this industry worthy of his attention in northern Queensland.

A great many other highly valuable plants in a commercial point of view could be successfully and profitably cultivated in the lately explored territory of the north, lying between the Herbert and Endeavour Rivers, such as the *Quintohou* or India-rubber Tree (*Siphonia elastica*), *Gutta Percha* (*Isopandra Gutta*), *Gamboge* (*Hebradendron gambogeoides*), *Palm Oil* (*Elais Guineensis*), *Quinine*, yellow bark (*Cinchona calisaya*), *Quinine*, red bark (*Cinchona succirubra*), *Ipecacuanha* (*Cephaelis Ipecacuanha*), and a host of other tropical exotics.

The *LAC INSECT* (Homoptera Coccida), and the plants it inhabits.—My attention has been recently directed to the commercial importance of the produce of this insect, and I am at present in communication with several correspondents in India and China to endeavour to obtain a supply of the best species of insects for the purpose of acclimatisation, as the trees upon which the insect subsists, and deposits in such large quantities the waxy substances from which the shellac and lac dye of commerce are prepared, flourish most admirably in various parts of the colony, but especially in the northern districts, where I believe the insect would be easily acclimatised. The trees upon which it lives in other parts of the world, and which are to be found growing to perfection in the Gardens and elsewhere in the colony, are the Indian Fig (*Ficus indica*), *Butea frondosa*, &c.; but I am also certain that the insect would take to many of our indigenous trees, and subsist as well upon them as the above, such for instance as the Moreton Bay Fig (*Ficus macrophylla*), *Rhamnus Vitiensis*, *Zizyphus quadrilocularis*, *Croton insularis*, &c. The produce of this insect is largely used in the arts in various manufactures in India, China, Japan, and various other countries; the value of the imports into England alone is from £800,000 to £400,000 per annum. It is, therefore, an article which is well worthy of the attention of the colonist.

The Sugar industry, as will be seen from the statistics given in this report, is increasing in importance in a great ratio yearly, the production of last year being fully two-fifths or 40 per cent. in excess of that of the previous year; and when settlement takes place upon the rich tropical lands of the north, so suitable for the industry, and with the further prospect of cheap Asiatic labour, I fully anticipate even a still larger increase in the production of this valuable commercial commodity.

I have it on reliable authority that sugar cultivation in this colony is causing great uneasiness and anxiety amongst sugar planters of Java and neighbouring islands, as they are convinced that, notwithstanding their advantage of cheap labour, that, from the superior quality of our sugar, due to the expensive and greatly superior machinery used in the refining process, that it will be quite impossible to compete with our growers, and that the fine quality of our sugars will drive their present low class sugars entirely out of their various markets.

I have at present about fifty (50) different varieties of sugarcane in the Gardens. It is now becoming almost impossible for the Gardens to act longer as a nursery for this plant; the requirements of the colonists for all these various different varieties is so immense that the requisite space cannot be set apart, and the soil and situation is not very suitable for the proper development of many of the plants. To meet the demands of those engaged in sugar cultivation, and for the successful growth of each kind, about a quarter of an acre would be required for each variety.

### ORCHARD HOUSE APPLES.

A few years ago we called the attention of our readers to some fruit of Cox's Orange Pippin we received from Mr. Abram Bass of Moat Bank, Burton-on-Trent, and which had been grown in an orchard house. The beauty of their colour, the wonderful delicacy of their flesh, and their richness of flavour were remarkable. Mr. Bass has again sent us this year some fruit of the same variety which in size and colour surpass anything we have ever seen, while the flavour cannot be excelled. They are indeed "Apples of gold." With these are also samples of Margil and the old Nonpareil, the latter so changed by its indoor cultivation as to be with difficulty recognisable.

But the lesson to be learned from this is, that Apples of this

class which are grown for flavour are so highly improved both in that respect and in appearance by being grown in an orchard house that we commend the system to all lovers of fine fruit. The texture of the flesh and the delicacy of flavour are such as cannot be found in any Apples grown under any other conditions. Such is the effect of this system of growing Apples, Mr. Bass informs us, that the state of ripeness is so advanced that the fruit does not keep so long as it ordinarily does when grown in the usual way.

It might be worth the while of fruit-growers who can appreciate good cultivation to pay a visit to Moat Bank in the season when gardening operations are going on, and see for themselves what two ardent amateurs—for Mrs. Bass is herein included—can do when stimulated by a love of their pursuit. It was our privilege to see the fruit houses there when they were in their best condition about two months ago, and we can testify unreservedly that we never saw better Grapes in the vineries nor finer fruit in the orchard houses than we saw at Mr. Bass's. *Apropos* of Grapes, Mr. Bass has been good enough to send us a handsome bunch of Muscat Hamburg as well set as any old Hamburg could be; and though rather red than black in colour the flavour is very rich, and justifies Mr. Bass's observation, "*Nimum ne crede colori*"—that is, "A good horse is never a bad colour."

### EARLY WRITERS ON ENGLISH GARDENING.

No. 8.

JACOB BOBART.

THE sixteenth century was the birth-time of botanic gardens. Italy led in this most effectual movement for the promotion of a knowledge of plants and their cultivation. The first established was at Padua in 1533, the movement was communicated to Switzerland and Germany, and in England the first botanic garden was established in 1632 at Oxford, and its founder was Henry Danvers, Earl of Danby. He gave five acres on the banks of the Cherwell, on the south side of St. Mary Magdalene College. He built greenhouses and stoves, enclosed the garden with a stone wall 14 feet high, erected a house for its superintendent, and engaged the first—JACOB BOBART.

The Earl of Danby was a gentleman commoner of Christchurch, and his mansion, Cornbury, was in Oxfordshire. Wood states that the Earl, "being minded to become a benefactor to the University, determined to begin and finish a place whereby learning, especially the faculty of medicine, might be improved." He gave £250 to purchase the meadow ground near the Cherwell. The tenant was bought-out in 1622, and the University took a lease of the ground from Magdalene College, paying yearly 40s. The first stone was laid on St. James's Day (July 25th) the same year. The enclosing wall was not finished until 1633, and it had then cost the Earl more than £5000. He then had it planted with "divers simples for the advancement of the faculty of medicine." John Tradescant was to have been the Professor of Botany, but the occurrence of the civil war, and then the Earl's death in 1644, prevented the arrangement. He devised to the University the rectory of Kirkdale in Yorkshire, for the use of the garden—that is, for its keeping and a stipend to the professor and gardener. The revenue not being sufficient no lecture was read until 1669, when the King's Professor of Botany, Dr. Robert Morison, accepted the appointment for a stipend of £40.

The Botanic Garden, or, as it was originally named, the Physic Garden, occupies the ground that had been the cemetery of the Jews; when they were expelled it became the property of St. John's Hospital. The gateway of the Botanic Garden was designed by Inigo Jones, over it is a bust of the founder; and the statues of Charles I. and II., one on each side the gateway, were purchased with the fine paid by Anthony Wood, the Oxford historian, for a libel on the Earl of Clarendon published in the first edition of the "*Athenæ Oxonienses*." Two large Yews were pruned and clipped into the form of giants. They were much satirised in ballads written in 1662 and 1664.

Jacob Bobart was a German, born at Brunswick in 1599, and consequently was thirty-three when he came to Oxford in 1632. Therefore Mr. Evelyn was not wrong when in 1664 he described him in the following sentence of his "*Diary*":—"Went to the Physic Garden where were two large Locust trees and as many Platani (Plane trees), and some rare plants under the culture of old Bobart." Dr. Plot bears testimony that he was "an excellent gardener and botanist," and that

he was assiduous in collecting plants into the garden under his charge is proved by its catalogue which he published. This is entitled, "Catalogus Plantarum Horti Medici Oxoniensis. Sc. Latino-Anglicis et Anglicis-Latinis. Res alphabetico ordine accurate exhibens. 1848."

In the address "To the Reader" there is this compliment paid to "Bobart," as it is there spelt, that the catalogue is of the very valuable contents of the garden so largely increased in a short time by his diligence, care, and industry. There were then sixteen hundred "stirpes," but very many were varieties—for instance, of Primulas there were "Feild Cowslips, Feild Oxelips, Double Pailges, Cowslips two in a hose, Feild Primrose, Double White Primrose, Single White Primrose, Single Purple Primrose, Single Blue Primrose, Greene Primrose, and Corled Cowslip."

Bobart was an entomologist as well as botanist, for Ray, writing to Aubrey, says—"I am glad that Mr. Bobart hath been so diligent in observing and making a collection of insects."

Bobart died in the eighty-first year of his age, in the garden-house, on the 4th of February of 1879, and was buried in the churchyard of St. Peter-in-the-East, Oxford, and a tablet to his memory placed against the church wall. His portrait was painted by D. Loggan, and an engraving from that picture is copied by our wood-engraver. Beneath the original engraving is this couplet—

"Thou German prince of plants  
each year to thee  
Thousands of subjects grant a  
subsidy."

In the British Museum is an album (probably his son's) in which is this characteristic autograph—

"Think that day lost whose descending sun  
Views from thy hand no noble action done.  
Thy success and happiness  
is sincerely wished by  
"Ja. Bobart, Oxford."

The will of Jacob Bobart the elder was proved in the Court of the Chancellor of Oxford, and is there preserved. It is dated 2nd of November, 1877. The will of his son Jacob was proved in the same Court, and is dated 2nd of January, 1730.

The peculiarities of those who interest us are noteworthy, and therefore I jot down that on festive occasions Bobart decorated his beard with silver tags, and that he had as his following companion a goat instead of a dog. He always spelt his name Bobart, but his son as uniformly substituted an *a* for the *e*.

He was twice married. By his second wife he had no issue, but by his first three sons, Jacob, Joseph, and Tilleman, as well as seven daughters. Jacob succeeded him as keeper of the Oxford garden. Tilleman Bobart countersigned in conjunction with H. Joynes and J. Vanburgh the account of work done for the Duke of Marlborough at Blenheim in the concluding months of 1709. His brother Jacob devised to him the chief part of his property.

Bobart the elder's will, after the usual religious preface and declaration of the testator's being "of good and perfect mind and memory," directs his body "decently to be buried in the churchyard of Saint Peter-in-the-East, in the city of Oxon, near my dear wife Mary." It devises "unto my eldest son Jacob Bobart the lease of my Greyhound Inn and mea-

dow," holden from St. Mary Magdalene College, upon condition that he paid "unto my daughter Ann the sum of ten pounds yearly" during her life. The testator's son Joseph appears to have been then dead, for he devises a silver cup that was Joseph's to his son Jacob, "with all my garden plants and half my books." To his son Tilleman he devised "the lease of my houses at Smyth Gate," leased from the Oxford Corporation, but his executrix, who was his second wife, was to have during her life the rents and profits. To Tilleman he also

bequeathed the other half of his books. To his daughter Catharine he bequeathed £30; to his daughter Arabella, £40; to his daughter Elizabeth, £40; to his daughter Margaret his tenement in George Lane, Oxford, but his executrix to receive the rent during her life. To his daughter "Mary, wife of Richard Collier," he bequeathed £5, and to his daughter Ann 20s. a year. In conclusion he made his "well-beloved wife Ann" his executrix and residuary legatee, and asks his friends, Mr. William Shaw and Mr. Richard Moons, to assist her, and in return bequeaths to each 5s., "to buy them gloves."

A poem, entitled "Vertumnus. An epistle to Mr. Jacob Bobart, Botany Professor to the University of Oxford, and keeper of the Physic Garden. By the author of 'The Apparition' (Dr. Evans) 1713," has been considered as addressed to the elder Bobart, but no mention is made of him; it is an eulogium of his son similarly named, unless these couplets may be taken as an allusion to the first formation of the Oxford garden.

"All plants which Europe's fields contain  
For health, for pleasure, or for pain,  
Her squares of horticulture yield,  
By Danby planted, Bobart tild."

Fig. 77.—JACOB BOBART.

Knowing that Mr. Henry Tilleman Bobart some years since was collecting materials for a biography of his ancestor I wrote to him on the subject. He obligingly sent me some MSS., but they related chiefly to the descendants of Bobart the elder. This is especially the case with the very full pedigree he has prepared, but I obtained from it the Bobart crest, an Oak branch of silver bearing golden acorns, and his signature, of which this is a copy:—

Jacob Bobart.  
1659

—G.

DUNORLAN,

TEN SEAT OF B. E. COLLINS, ESQ.

It was on a lovely afternoon in September that I set out from Tunbridge Wells in search of Dunorlan, in response to a courteous invitation from Mr. Walker, who has had charge of

the gardens for, I believe, nearly twenty years; in fact, if I am not mistaken, most of the laying-out of this place was done under his supervision from the plans of Mr. Marnock. The neighbourhood of Tunbridge Wells abounds with fine houses and beautiful gardens. After passing many such I came to an entrance-gate with a pretty little lodge charmingly embowered in flowers and climbing plants, opening into the finest avenue of Deodars I have ever seen. The trees stand on turf; every one of them was in perfect health, flourishing with such vigour as would astonish those who regard this as a "doubtful" Conifer. The densely-clothed pendant branches resting on the turf, and tapering upwards to a height of about 80 feet, absolutely glistened with health, the silvery glaucous hue, so conspicuous in this Conifer when it is thriving, being finely developed. "Can you tell me the name of this place?" "Dunorlan," was the reply; and thought I, a treat is in store for me, so it proved.

The Cedar avenue takes a bold sweep down to the house, which stands upon a sheltered but commanding position. The building and its surroundings are equally fine, a noble pile with wide open upper and lower gravel terraces, each bounded by massive walls with open balustrading, tazas, vases, and flights of stone steps. At one end of the building is a conservatory in admirable keeping; at the other a croquet lawn, fringed on the north side by a belt of shrubs and trees, and with some magnificent Conifers, some standing out singly and others clustering behind a temple at its eastern end, the whole commanding a landscape of great beauty. Banks sloping in charming irregularity downwards to a valley; on this side dressed grounds abounding with shrubs in groups, Conifers clustering together in rich profusion and picturesque contrast, and occasional fine specimens standing out alone with the happiest effect. The deep rich green of Rhododendrons, a lake with winding shores—its waters not all visible from one point, but passing behind banks and among the cool shade of trees, with glimpses of walks leading to other points of interest. On the other side banks rise gently to an open undulating country, agreeably broken by trees with dark Pine woods in the distance.

Such briefly are the general features of one of the most charming scenes it has ever been my privilege to behold; nothing incongruous is to be seen; unity and harmony everywhere prevail, and yet there is variety even to excess. Let us explore, for there are ample details to reward our efforts, and in doing so we will strive to combine instruction with enjoyment.

By a walk leading from the carriage front to the conservatory there are some specimen Rhododendrons planted singly; the idea is an excellent one, and the position good. The green foliage already affords a pleasing relief and break to the brightness of the glass, and some day they will probably render what is usually a somewhat dull spot a most attractive one. We already have in this country Rhododendrons upwards of 80 feet high. Let the reader picture a single specimen of such sorts as Alarm or Mrs. J. Clutton of that height, well proportioned, and with branches to the ground laden with flowers. We have as yet nothing in our gardens to compare with this, but another generation may hope to see it. A gay bank of flowers in the conservatory was screened from the direct rays of the sun by means of blinds of an ornamental character made to slide along the interior of the roof, and not up and down in the usual manner, giving to it a novel appearance, and rendering the building an enjoyable resort in the hottest days of summer.

Passing from the terraces downwards to the lake by a walk winding among turf-clad banks among Conifers we come upon a Rose garden of a novel design and very picturesque appearance. On the upper side huge masses of rock irregular in outline protrude from the bank, and are partly concealed by a rich trailing growth of *Escallonia macrantha*; on the other side a dense Yew hedge with masses of shrubs serve admirably to screen the Roses from cold cutting winds, and its formality is agreeably relieved by an arcade of ironwork covered with climbing Roses, under which the walk passes.

Many features of interest present themselves in the lower part of the grounds by the lake. A rocky cascade fringed with trailing *Ocotoneaster* and a somewhat wild but picturesque growth of shrubs, a winding stream among huge rock boulders, and shady nooks with arbours; all very enjoyable, and possessing an air of quiet seclusion and retirement that is in delightful contrast to the open expanse of the upper lawns. It is after passing among such objects of quiet beauty that we come to an arbour almost concealed in a clump of trees, and overlooking the view we have had engraved. The surprise is a complete one, and the effect is delightful. The avenue is

17 yards wide and 260 yards in length. The trees are the Douglas Fir and Deodars planted alternately; they have grown considerably since the photograph was taken, and are already very ornamental. Some day, in another generation or two, when they have grown into stately old trees the effect will be one of surpassing dignity and grandeur. It was a bold step on the artist's part to introduce such a feature at such a point, so totally at variance with the stereotyped rules by which the operations of most landscape gardeners are governed. It is undoubtedly an avenue, but it is not a mere formal one and nothing more—just two parallel lines of trees farther apart than usual. No, there is meaning and expression in every part of it. It is most attractive in itself if regarded simply as an avenue, but it is further replete with interest by the objects to which it leads and others which open into it. At the bottom is a fountain, bold and elegant in design, with an expanse of turf around it in fine proportion to its size. At the top a temple, and at intervals along the sides groups of statuary and openings affording views of the rosery and lake; groups of shrubs and other important features all attracting the eye, so as to afford a continuous and pleasing variety.

The temple standing at the top forms a shrine for an exquisite group of statuary in pure white marble, by Adams, of the Lady of the Lake and her dog "Brave Lufra." The attitude of Ellen is wonderfully natural and full of grace; her face wears an air of abstraction and deep thought, a Rose has fallen from the hand which hangs listlessly by her side, and Lufra with uplifted paw and pleading gaze vainly strives to attract the attention of his mistress. The work is the conception of a master mind, the execution that of a clever artist. The building of white stone is itself an elegant and costly one, and its interior is beautifully tinted and relieved with delicate tracery, the whole forming a most graceful tribute to the genius of Sir Walter Scott, and is a commanding and most important object in this beautiful place.

A splendid specimen of the Mount Enos Fir, quite 50 feet high, is worthy of especial note. Very many other kinds are evidently at home here, but a detailed account of them is uncalled for.

Alterations and additions are being made to the two kitchen gardens, and considerable additions are also being made to the glass houses. A range of vineries contained some good Grapes, and a glazed Vine border betokened high culture and careful tending, which indeed were evident everywhere.—EDWARD LUCKHURST.

## NOTES AND GLEANINGS.

WE are authorised to announce that the GREAT FRUIT SHOW of the Royal Horticultural Society, which is to be held on the 10th of November, will be open for two days; that on the evening of the first day the Exhibition will be lighted by gas, when the public will be admitted on payment of 1s.; and that the whole amount of the prizes will be paid in full, and not at the rate of 50 per cent. reduction, as was announced in the early part of the year.

WE have received Bulletin No. 2 of the INTERNATIONAL HORTICULTURAL EXHIBITION of 1877, which is to be held at AMSTERDAM, and it is accompanied by a "Project of Programme" of the vegetable products which are to form part of the Exhibition. This will not be the least interesting part of it, seeing it embraces all the most valuable of the vegetable products used for food, and in the arts, manufactures, and medicine, such as cotton, tobacco, Peruvian bark, madder, indigo, sautehouse, and gutta serena; fats, including fatty oils, etheria (essential) oils, substances used for paper, cereals, Catechu, Vanilla, Rhubarb, and Sarsaparilla.

THE first Show of the Hull, Yorkshire, and Lincolnshire POMOLOGICAL SOCIETY will be held at Hull on Tuesday and Wednesday, October 26th and 27th.

THE MADRESFIELD COURT GRAPE, which in some places has cracked its fruit, is this year in splendid condition in the cool vinery at Chiswick. The berries may be called enormous, and the colour jet black with a fine bloom. It is well to know, however, that this fine Grape requires a little heat in cold wet autumns like the present, for if there is too much moisture in the house the berries mould and drop. The bunches at Chiswick are quite a sight, and the berries have never shown any sign of cracking.

WE have received through the kindness of Sir William Bagge of Stradsett Hall, Downham Market, TWELVE ACORNS of

remarkable size gathered from a tree, the average crop of which is very little less in size to those sent. They are from the common Oak (*Quercus pedunculata*), and measure 1 inch and seven-sixteenths long, and 8 inches and three-eighths in latitudinal circumference. The aggregate weight of the twelve acorns was over 6 ozs.

— We have received from Messrs. James Carter & Co. fruits of the GREEN GAGE TOMATO grown under ordinary cultivation at their seed farms. The fruits were perfectly ripe, of an orange-yellow colour, and their flavour when cooked was excellent.

— MESSRS. CARTER & Co.'s ROOT SHOW is to be held in November in the Agricultural Hall, Islington. Turnips, Potatoes, and Mangel Wurzel are included. The prizes are numerous and liberal.

## NOTES ON VILLA AND SUBURBAN GARDENING.

**HYACINTHS AND OTHER BULBS.**—Perhaps there is no flower more sought and made more of in a decorative point of view than the different sorts of bulbs. The easy and inexpensive process in the matter of treatment necessary to bring them to perfection, and the certainty of flowering them finely, have doubtless been stepping-stones towards the ever-increasing sale of enormous quantities yearly. This being so, coupled with the undoubted fact that the number of amateur growers increases yearly, it may be well, now that the season has come round, to devote a few notes to their interest. Of course I assume as being well known that these bulbs can be well grown in glasses, pots, or pans, and in beds in the open ground. In glasses they should have been put in some time ago if wanted early, because they will not bear the forcing those grown in pots will; but for later flowering glasses may yet be used for them.

Although the season for potting Hyacinths, Tulips, Narcissuses, Crocuses, &c., extends to the end of November, yet it is best to get them in a month earlier if possible, especially if they are to be forced early; for instance, I want some flowers of the sweet little white Roman Hyacinth, and one or two other colours by Christmas. These have been put in sometime, while the general lot will be potted in a few days. I do not lay much stress on any particular mixture of soil for them, because I have tried several, and for ordinary purposes I do not see much difference. Rather would I say to new cultivators, Go where you can obtain well-ripened weighty bulbs, and let them be put in at the proper time; let them have ample time for rooting in the soil before the bulb shows a leaf. This applies to all sorts; and a soil in which they do as well as any, and which is likely to be obtained easier by our amateur friends, is loam and sand, adding one-third leaf mould to the quantity of loam got together; drain the pots well, and pot rather firmly, so as to keep the bulb in its place. If the soil is heavy do not pot so firmly; and if any of the bulbs have started into growth at the top, and are somewhat soft in consequence, append a mark to it, and place the bulb in a little silver sand when potting, and let such as this be the last to take in for forcing, and it is a question if they ought to be forced at all.

As well as Hyacinths and Tulips there are Narcissuses, Crocuses, Snowdrops, Jonquills, Scillas, Grape-Hyacinths, Solomon's Seal, and Lilies of the Valley, and some others, may all be potted in the same way and at the same time, and, where there is no special convenience nor any special object in view, be treated alike—that is, after potting stand them on a bed of ashes, cover between and over the pot with a foot thick of the same material, marking each kind with a long label, so that when a few pots are wanted out there will be no difficulty in finding them. Now in case any fancy baskets or pots, stands or vases, are planted with them, a coal-ash bed will not be the proper place to use, but they may be placed in a cellar on clean boards, and if not in the dark be made so by a covering of some sort. These must be looked to with regard to water, the soil made moist after potting, and the bulbs allowed to become dry before coming up, or it is likely to induce mildew and decay in the bulb. Those outdoors will need no water, as from the dampness of the ashes this will be sufficient. In cultivating bulbs of this kind when they are being grown under glass water is a special need. The roots of most are abundant and fleshy, the spike of bloom generally large, and needs plenty of water, and, after the spike appears, liquid manure twice or thrice a-week will benefit them.

We now come to the bedding system of growing Hyacinths, Tulips, &c., for which purpose there are distinct sorts cheap and good. The beds should be prepared for them as soon as it is convenient for the bedding plants to come off, and the bulbs planted before severe frosts come on. They will do well if the ordinary soil of the bed is dug or trenched deep, adding 4 inches or so of rotten manure, placing it about a foot under the surface, the bulbs planted in rows; and it will be no harm, but likely do good, if a little sand is distributed in the bottom

of the hole or drill. Make each bulb firm, and cover over carefully. They may need some protection in winter; but I should like to see more town gardens planted with bulbs, also the windows of streets more frequently decorated with them. The balcony boxes should be planted with two or three colours, also room vases of the more substantial kind, in which these things thrive amazingly; but as a rule the single Hyacinths do best both for early forcing as well as outdoor culture. Unnamed bedding sorts can be bought in mixture, as so also can Tulips, &c., and I think a little cheaper than others, which, though they are not to be depended upon in securing accurate placing of the colours like named sorts, they are most useful for a fair display of bloom and for cutting purposes. Any respectable nurseryman's catalogue will afford information as to colours named or unnamed.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

We much regret to hear that Mr. Douglas is too unwell to contribute his notes this week.

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

JERSEY.—Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.  
LOUGHBOROUGH.—November 15th and 16th. Mr. W. Pallett, 55, Baxtergate, Sec.

## TRADE CATALOGUES RECEIVED.

Thomas S. Ware, Hale Farm Nurseries, Tottenham.—*Catalogue of Florists' Flowers, Roses, and Climbing Plants.*  
Sonntag & Co., Seed Merchants, 614, Merchant Street, San Francisco, California.—*Catalogue of Shrub and Evergreen Tree Seeds.*

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

GRASS TERRACES (*J. P. of York*).—The wall ought to be next the gravel terrace if you have a wall at all appearing above ground, hence we suggested your having a sunk fence or a tall fence as the boundary line at the base of the slope. The plan shown in your sketch would have a good effect looking from the house; but whether the outer wall as the boundary of the third or second grass terrace would be an objectionable object when looking towards the house when approaching it from a distance, is a matter which you alone can determine. If it will not be an eyesore we see no objection to your plan being carried out, and we should not hesitate to carry it out, especially as you by present arrangements are debarred views of the valley or scenery around. The middle or first grass terrace may be twice the width of the others.

HEDGE OF ROSEMARY AND LAVENDER (*Edward Liddell*).—Slips or large pieces slipped off from whence they proceed may be inserted two-thirds their length in the ground and firmly at 9 inches distance apart. It may be done now, or preferably in March or early April. Light sandy loam is the most suitable soil; and if you have not plants by you we should sow seed early in April in rows a foot distance apart, and the seeds about an inch distance apart, thinning to 9 inches. The seeds should be covered about three-quarters inch deep. You will need to protect from rabbits.

FORMING GRAVEL WALKS FOR KITCHEN GARDEN (*Senex*).—You will need to form a foundation for the walks 6 inches deep of any rough material you may have at hand, as brickbats, stone, or large gravel, and this should have the surface covered with finer rubble, or at least all irregularities should be filled-up, forming the surface roughly, and then covering it with finer material. We presume you can obtain ashes, and these in a dry state should be formed into a mortar-like consistence by mixing with boiling coal tar, and this should be laid on the walks about 8 inches thick evenly, and to the required surface, and sprinkle over it the small granite chippings, and let it be cool and will bear a roller rolled thoroughly, by which the granite will become part of the walk, and will wear capably. The walks thus made will last many years, and no weeds will grow on the walks. You will need a tile, or preferably a stone, edging to the walks.

PLANTS FOR WINTER BEDDING (*Mary, Dublin*).—You could not have anything better than Wallflowers, variegated Arabis, Violets, variegated Kale, crimson-leaved Beet, Golden Feather Pyrethrum, Daisies, the Aucuba-leaved being very fine; and Primroses in variety.

STRAWBERRIES (*H. B.*).—For general purposes there is no better Strawberry than *Vicomtesse Hérisart de Thury*. As to whether the plants planted out in February will bear fruit the same year or not, that will depend on their strength and the soil. If good plants they will produce some fruit.

**VINE ROOTS DISEASED** (*A Subscriber, North*).—We have no doubt whatever that the disease is due to the pernicious nature of the subsoil, and we are the more convinced of this by the fact that other vines in the district are similarly affected. Four years ago we witnessed vines precisely in the same state—that is, the bottom roots died, and it was only by the emission of surface roots that the vines were supported. In the summer the foliage flagged, and the house had to be shaded, and the few surface roots were fed by a top-dressing of manure and copious supplies of water. In the autumn the vines were taken up and all the lower roots were dead, the surface roots being fresh and healthy. The lower portion was cut off just beneath the surface roots, and the vines were cut down and replanted, first, however, removing the subsoil, concreting and draining the border, and placing in prepared soil to the depth of 2 feet. The remedy was complete, and the vines which were nearly dead by the loss of their lower roots have since produced grapes which have seldom been surpassed for size and quality, and no better grapes have appeared in Covent Garden this year than the produce of those vines. We can only advise you to adopt the same treatment, and we believe you will obtain good grapes. Unless you remove the subsoil your vines will never be satisfactory.

**FIRST-PRIZE DARK PLUM AT STAMFORD SHOW** (*O. E. Bracebridge*).—We are informed that it was the Gollath, and was exhibited by Mr. Ewart, Apethorpe, Wansford.

**FERNICE SEEDS**.—"H. C." and others would be obliged by being informed where these can be purchased. They would pay for being advertised.

**BOTANICAL TERMS**.—CRYSTALS ON GRAPES (*J. W.*).—Henslow's "Dictionary of Botanical Terms," published by Messrs. Groombridge. A saturated solution of alum will deposit crystals on plants.

**GATHERING PEARS** (*R. H. F., York*).—There is no special time for gathering any Pears. Pears are fit for gathering when their stalk parts from the spray if they are raised a little above a horizontal position. Store them in single layers in a cool dark room.

**FERNS**.—VINES (*E. J. S.*).—We stated that we could not name the Ferns because they had no spores on them. Any queries about vines will be answered as soon as we receive them.

**CAMELLIAS CASTING THEIR BUDS** (*A. H. E.*).—We should attribute the casting of the buds to the check consequent upon the potting just prior to placing outdoors, and this it seems also entailed loss of leaves, and a second growth, resulting we are not surprised at the first buds falling, but cannot account for those on the second growth falling, unless it be from the drier atmosphere of the house, the buds not being sufficiently developed, nor the wood ripened. Nothing that you can do now will save the buds from falling; but by careful watering through the winter, and by having the buds well formed before placing outdoors, or better not at all, keeping in a cool airy house and shaded, a recurrence of the evil may be avoided.

**BULBS PLANTED-OUT IN GREENHOUSE** (*B. B.*).—They would succeed admirably, and *Lilium auratum* and *speciosum* vars., with *Sparaxis*, *Tricoma*, and similar plants would answer. *Geraniums* would not do until after March, but *Mignonette* would do soon early.

**CLIMBING PLANTS FOR CONSERVATORY** (*Rob Roy*).—*Bignonia jacinthoides* splendens, *Mandevilla suaveolens*, *Passiflora Imperatrix* Eugénie, if moderately warm, or if cool, *P. Comte Nesselrode*, *Taenosa Van Volxemi*, *Habenaria fascicularis*, and *Bignonia Tweediana*; and if you have a north roof *Lapageria rosea* and *L. alba*. The *Lapageria* does best in fibrous rough peat, and requires extra drainage, as the watering is required to be very liberal. All the others succeed in a compost of three parts fibrous loam, and a part leaf soil, with half part sandy peat, and the same of old cow dung and sand. They do very much better planted-out in borders than grown in either pots or tubs.

**CLIMBERS FOR UNHEATED GREENHOUSE** (*B. B.*).—The following, though not climbers, would, trained to wires, answer: *Oenothera floribunda*, *Chimonanthus fragrans*, *Eugenia Ugni*, and *Pittosporum Tobira*; or climbers *Cappifolium latum*, *Clematis Henryi*, *Jasminum revolutum*, and *Lardisbala biternata*. *Solanum jacinthoides* and *Passiflora corallina* would also succeed.

**PEARS GRAFTED IN SPRING** (*W. W.*).—Remove the bandage at once, and prune when the leaves have fallen, heading-back to about a foot. They will not require any protection in winter, for they are hardy.

**OUTDOOR VINES** (*F. L.*).—Count the first eye at the base of the shoot, and cut at the one next above it. Do not take out the eyes now or at pruning, but leave all and rub off the shoots you do not want. Dissolved bones will answer, but are not so lasting as crushed ones, and the way you propose applying them and the stable litter is right.

**GRAFTING PEAR TREES** (*F. L.*).—The pyramid and espalier trees you wish to graft with more desirable kinds should have the heads cut off at the time or a short time only before grafting. Whip-grafting we consider the most desirable mode, and you may cut off all the branches to within 6 inches of the main stem, and graft all those as well as the leader. Make the surface smooth by paring with a knife after sawing-off the branches. Place the scions on the upper preferably to the under side of the branches. The scions should be removed from the trees before their buds begin to swell, and have their lower ends inserted in moist soil. The scions will have three or four buds in about 4 inch of shoot, and you will hardly be able to have three buds in a 5-inch length, with one bud near the lower end, and the scions will need to have one, better two buds, clear of the grafting-wax or clay. The scions are not to be dipped into the grafting-wax, but securely bandaged with a ligature of mastic, and then apply the wax so as to effectually exclude air. Graft when the Pear trees generally are commencing to grow, or from the middle to the close of March. We do not know the grafting-wax to which you allude, but the following given in the "Year Book" has the advantage of not being required applied warm:—"Yellow wax 1 lb., turpentine 1 lb., Burgundy pitch 8 ozs., mutton suet 4 ozs. Melt all together and mix thoroughly, and leave them to cool. Form the mass into small balls, as it will not stick to the fingers, and use them when opportunity offers." For your purpose we consider the usual clay covering would answer and be cheaper.

**HEATING GREENHOUSE, &c.** (*B. O. L.*).—We do not approve of your proposed mode of heating, for though water will circulate on a level below that of the boiler, it is always sluggish, and would in your case we think boil over or be blown-out in the cistern or tank from which the supply of hot water is to be drawn for domestic purposes. The return pipes should be on a level with the boiler above rather than below the return-pipe of the boiler. In your case the majority of the piping is below the boiler and almost all return, and unless you can lower the boiler to the level of the pipes in the greenhouse and

boothouse we should not advise its adoption. Could you not have the boiler in the greenhouse or in some place adjoining? The plan, other than the level, would answer well, the boiler from the dimensions given is capable of heating the piping required. It appears to us you would have too little piping and a great deal of it useless, being taken-up in connection between the houses; but as you give no dimensions we may be in error on that point.

**WINTERING GERANIUMS** (*M. W.*).—Not having a greenhouse you may safely winter the plants in a room from which frost is excluded, and we can only account for your former failure by being in a room too cold. Now if you will take-up the plants and strip from them every leaf except any at the points of the shoots not larger than a shilling, and trim-in the roots so that they may be potted in 4-inch pots in moderately moist, rather light, and moderately rich loam, giving no water, or only a little to keep the shoots from shrivelling, until March, and admitting air freely whenever the temperature of the room is over 50°, and not so as to lower below 45°, avoiding a draught, and not allowing the temperature to fall below 35°, better 40°, for safety, we guarantee greater part of the plants will survive the winter; and if you cut-in any irregularities of growth in March, and water as required afterwards so as to keep the soil moist, we consider you will have nice plants for planting-out in May. Another plan is to have some wood boxes made of half-inch deal, planed on the outside and edges for neatness, the length and width of the window-sills, and 4 inches deep, the bottom being bored with about half a dozen holes half an inch in diameter, and a red hot iron run through each, the holes being to let out superfluous water, and over each of inside may be placed an oyster shell or a piece of pot, and then an inch of the sittings of the soil used for filling the boxes, which is best of sandy loam without admixture. Place a little soil over the rubble, introduce the plants all the leaves stripped off, and the roots cut-in to about 3 inches of the stem, placing them closely together, and fill-in between and over the roots, leaving about half an inch from the top of the box to admit of watering. These boxes placed in any window of a room from which frost is excluded will winter safely, treated as above described. The box will rot or damage the window-sill if you do not place under each a piece of zinc, and if this be turned-up at the edges no water can possibly come upon the window except of neglect. The plants may be potted-off from the boxes in March, the plants grown-on in frames or elsewhere, as we have seen boxes are no gas from the boxes in May, and do remarkably well. Where the boxes are no gas must be consumed, or the plants will suffer. A third plan is to strip the plants of their leaves, not to trim-in the roots or only any very straggling ones, and to place the plants buried in dry sand in a cellar, from which they should be taken in March, potted, and grown-on in frames. The plants should be cut-back in March or early in April if they are straggling in growth, so as to form bushy plants.

**WINTERING FUCHSIAS AND HELIOTROPES** (*Idem*).—Without a greenhouse lay the plants on their sides in front of a south wall, and before severe weather, taking care the plants are not frosted, place in a cellar from which frost is excluded and keep dry, but the wood is not to be allowed to shrivel from overdryness. In March or April remove the plants to a window and prune, re-potting when the young shoots are about an inch long. Outtings of *Heliotropes* should be of the young wood, the points about 8 inches long inserted in sandy soil, and placed in a cold frame if in summer, or in spring and autumn, affording bottom heat, shading from sun.

**BLACK HAMBURG GRAPES DEFICIENT IN COLOUR** (*M. T.*).—The causes of the grapes being red instead of black are probably defective root-action, not having the bunches well shaded by the leaves, and insufficient ventilation. A good supply of weak tepid liquid manure during the time of colouring, less thinning of the leaves, and more air, are the obvious remedies.

**SELECT FRUIT TREES** (*W. Seymour Fraser*).—We have selected and set down the varieties in the order of ripening. *Apple*: Irish Peach, Kerry Pippin, Gravenstein, Golden Winter Pearmain, Cox's Orange Pippin, Golden Bellecote. *Plums*: De Montfort, Transparent Gage, Cox's Golden Drop. *Cherries*: Black Tartarian, Duchesse de Pallan, Mary.

**SEEDLING CYCLAMEN CULTURE** (*H. A.*).—The seedlings sown about two months ago pot-off singly in small pots, and as you have only a cold greenhouse, place them on shelves near the glass and keep them moist during the winter. In May move them to a cold frame, and there keep them duly watered, but rather sparingly in June and July. In August they may be shifted into larger pots, and being kept rather moist, close, and shaded from bright sun they will start into free growth, and should be moved to the greenhouse in October, placed on shelves near the glass. Keep them moist, but not overwatered. They will flower during the winter and spring. Frost must be excluded. The soil most suitable is three parts light fibrous loam, one part each leaf soil, sandy peat, and silver sand, well mixed, with good drainage.

**SITE FOR FRUIT-BOOK** (*J. E.*).—Of the two sites submitted to us we should prefer that of No. 1 from its northerly aspect. The slight warmth it would derive from the dining-room fire on the opposite side of the wall will probably exclude frost. No 2 would answer, and appears to give the greatest accommodation for fruit shelves, but it does not appear how you will be able to keep out frost in severe weather. There is also the same objection to No. 1, the heat from the wall not being sufficient in severe weather to maintain the temperature in the fruit-room above freezing-point, and the heat at other times may cause too dry an atmosphere, and so cause the fruit to shrivel or unduly ripen. We have, however, a room similarly situated as No. 1, and it answers very well, but we have a window, or rather skylight, and by raising this we can admit air, having a shutter to insure darkness and keep out frost.

**LATE-KEEPING DESSERT APPLE** (*W. R.*).—You cannot have a better than the Sturmer Pippin. Add to your Pears Beurré Hardy.

**NAMES OF FRUITS** (*Z. A. B.*).—1, Beurré Diel; 2, Brown Beurré; 3, not known; 4, Easter Beurré. (*Harvey*).—1, Forelle; 2, Calabrese Grosse; 3, Beurré Diel; 4, Fondante de Noël; 5, Beurre Rose; 6, Beurré d'Alsace. (*R. Calvert, Clapham*).—1, Bedfordshire Foundling; 2, Kewick Codlin; 3, Hawthornden; 4, Dutch Codlin; 5, not known; 6, very like Jargonelle; 7, Marie Louise; 8, Winter Nalis; 9, not known; 10, Beurré Rose; 11, Louise Bonne of Jersey. (*O. P.*).—3, Dutch Codlin; 4, Beauty of Kent; 5, Aston Town; 6, Suffolk Thorn; 7, Thompson's. (*R. B. L.*).—1, Green Tiffin; 2, Braddick's Nonpareil; 3, Baxter's Pearmain; 4, not known; 5, Hoary Morning; Pear not known. (*T. A. Bickley*).—We cannot name Peaches unless we know the characters of the leaves and flowers. (*G. F. Barrell*).—1, Émile d'Hayot; 2, Beurré Sterckmans, a fine specimen; 3, not known; 4, Striped Beaufort; 5, Beurré Diel; 6, Uvedale's St. Germain, small specimen; 7, Millot de Nancy. (*John Emerson*).—Delaware. The smaller is Nonesuch.

## POULTRY, BEE, AND PIGEON CHRONICLE.

## "POT AU FEU" FOR CHICKENS.

At this season of the year especially all those who have gardens can do much for their fowls, as the refuse from the vegetables now is always considerable. We had the pleasure of going over an establishment the other day where an immense number of chickens and Ducks are reared annually for market purposes, and we found there that vegetables were introduced to a great extent among the cooked foods for the fowls. We know that many of our readers are very ardent poultry lovers, but they have not the means, opportunities, or wishes, many of them, to incur the trouble and heart-aches of exhibiting; still they are great producers of poultry meat as an article of food, and so to them a few hints on economising their foods may be valuable.

We are great advocates for cooked food, as we are convinced it goes much further and does more real good to the birds. We were originally indebted to Mr. Wright for pointing out to us the value of the food being cooked, or at least partially so; and since we put the plan into regular operation we have had every reason for knowing its benefit. The establishment to which we referred above possesses a large copper, and in this daily the *pot au feu* for the birds is prepared. All kinds of refuse vegetables are used—cabbage, celery, and lettuce leaves, the peelings of carrots, turnips, and potatoes, slices of beet and mangel wurzel, windfalls from the apple trees, and such miscellaneous vegetable produce are cooked in this copper.

When the mass is quite soft it is turned out and peppered with coarsely-ground black pepper, and seasoned quite lightly with salt. Then comes the mixing with the meal, which is changed every now and then. Fine sharps are always used, but this is mixed perhaps one week with ground oats, another with barleymeal, another with ground Indian maize, and so on.

Great pains are taken with the mixing, as much depends upon this, for if the food is sticky from being badly compounded or sloppy, not only would the birds not relish it nearly so much, but it would not do them one-half the good. It must be crumbly, and to render it so the meal should be gradually mixed with the vegetable compound with a strong spoon, and then when thoroughly mixed it can be kneaded with the hands into balls, and so distributed to the birds.

This may seem a long business, but if any keep several head of chickens, and go in regularly for producing table fowls, we are convinced they will be amply repaid by making this warm breakfast for their birds. We make a great point of its being warm, as in the cold winter months the number of eggs is thus greatly increased, and the birds always look fresh and healthy. Fowls fed regularly on this soft food in the morning, if they have a free run, will not need more than a good feed of whole corn in the late afternoon or evening.

Birds which have to undergo the wear and tear of being exhibited would hardly find this compound satisfying enough; but we do not prescribe for them, because their mode of living must depend upon the tact and experience of the manager; but we recommend this "*pot au feu*" to those who have a paddock or orchard for their birds to run in, and want to economise their food, making use at the same time of vegetable matter which would otherwise, perhaps, go to the garden rubbish heap.

The quantity to be made of this warm food will depend upon the size of the establishment, as either a small saucepanful can be made on the sitting-room fire for a pet pair of Bantams, or a copperful boiled-up for a farmyard full of fowls.

We do not only recommend this compound to economise food, or for using-up the green stuff, but because a mixture of vegetable food with the meal is of itself the greatest help to keeping birds in healthy and good condition. To those birds which live in a back yard or bare run all the year round a boiled compound of meal with some vegetables given warm we would especially recommend, for it will do them twice as much good given so than if they were always fed on mixed soft food or whole grain. We would not, of course, use this as a permanent diet throughout the year, but every now and then leave it off for a few days, and so by giving the birds a change of food they will return to their vegetable compound with greater avidity.

Some poultry-keepers have no garden, and only keep their birds in some few feet of back premises. To these birds our vegetable compound will be the greatest boon, for they can have boiled up for them the refuse leaves from the vegetables in household use, and the apple and potato parings, which in larger establishments, perhaps, would be considered to belong to the pigs rather than to the fowls. Only those who have tried it can realise the advantage of mixing green stuff with their chickens' food. We recommend all amateurs to take the matter seriously into consideration, and not to sanction the waste of a

cabbage leaf or a potato peeling, but to have them all thrown into the "*pot au feu*" of the chickens.—W.

## SPECIAL CLASSES AT THE CRYSTAL PALACE GREAT NATIONAL POULTRY SHOW.

MANY very erroneous opinions have been formed upon the nature and relative value of the two cups offered by the Baroness Burdett Coutts at the above Show, and as my name has been forcibly hinted at in connection with the subject through one of your contemporaries I will make a few observations upon the new classes.

The Baroness was anxious to support the Show, but preferred that her prizes should promote some humane object. The question being referred to me, I suggested the framing of the special prizes as they now appear in the schedule. The first one, for Undubbed Game, has called forth strange observations, because it was announced "that the Baroness wished to notify that this prize was directed against the growing tendency to cock-fighting." Your contemporary with one statement would try to make his readers believe there is little or no cock-fighting going on in this country, whilst with another statement he acknowledges the fact. Moreover, the Baroness's advisers are in possession of facts of a startling nature, which may sooner or later be brought to light; therefore the less said upon that subject just now the better.

Then, as to whether there is any cruelty or pain in the operation of dubbing, there can be no two questions. As there is considerable loss of blood, and during the healing process the birds lose considerably in condition; and not only condition, for the slicing off the comb, the shearing off the wattles, and the carving or slicing away at the skin of the face and throat, frequently alters the bird so much that he cannot be recognised—not even by his crow, for that also is mostly affected by the barbarous misuse of the scissors. Such being the case, I think the Baroness's wish is so far carried out as regards the question of cruelty.

Relative to the second cup, I am thoroughly surprised that so much misconception should have arisen. I considered the value of such a class would have been immediately apparent to any practical breeder. The idea of this class was suggested to me by the most successful and respected breeder of Brahmas, Mr. Horace Lingwood. His remarks to me are, "I believe you would find classes fill well for birds that are vulture-hooked, and as a trial it might be for all Asiatic breeds;" and he further dilates upon the intrinsic value of such birds for stock purposes.

Any person who has stock of his own, and can breed winners of these varieties, must acknowledge the fact that he is obliged to keep birds on his hands which are wholly unfit for showing, but which are invaluable for his breeding purposes; but by the class now open he can exhibit them, and as Mr. Lingwood says, "the public will be much amused," and many breeders of intelligence may receive instruction by viewing the breeding stud of successful exhibitors.

Why your contemporary should have taken such extreme views of the matter is best known to himself, for I have not found any person who does not feel that his observations are insulting to an extent wholly unwarranted. \* \* \*

In conclusion, I trust you know sufficient of me after so many years' intercourse to believe that I could not have had the intention either to "insult" or "disgrace" any person by the simple way in which this famous poultry class is worded. I feel convinced that the generality of the visitors will be wise enough to judge of the birds and their owners in a more common-sense and practical light than has been suggested, and I have no doubt there will be many magnificent birds shown fully vulture-hooked, and that they will in many instances change owners readily.

The class will be specially for vulture-hooked and other untrimmed birds as originally proposed; and as there are some exhibitors who do not scruple to pluck their birds, this class will at least give them the opportunity to show their birds honestly, and to meet other good vulture-hooked birds from exhibitors who would scorn to pluck their birds. I need scarcely add as a reminder that birds will not win which are not vulture-hooked.—F. CROOK, *Vine Cottage, Ferry Vale, Forest Hill, S.E.*

## ENTRIES AT OXFORD.

We have been favoured with the result of the entries at this Show, and are pleased to find they are so many. There are nearly fourteen hundred entries in all, which is extremely good considering the scarcity of chickens and the Alexandra Palace meeting so nearly clashing with it. Nearly every exhibitor of note is represented. The entries in the sale classes are very numerous, and the specimens will, to a great extent, be from the yards of well-known exhibitors. We will give a few of the entries in the various classes, as they may be of interest to exhibitors.

Dorkings muster very well, every class having more entries

than last year, the Coloured variety alone numbering twenty-eight pens. Spanish are more in quantity than last year, for this season there are twenty pens of chickens entered. In Cochins there is a falling-off, especially in Blacks and Partridges, for they only number fifteen pens in those two classes against thirty-nine in 1874; Buffs and Whites, however, make-up for them with two capital lots as regards entries. Brahmas, Dark and Light, number twenty-nine and thirty-four pens respectively. Game are well represented, for there are over 190 pens. We always find a crack lot of Game chickens here, and this season's bids well to be no exception. Of Hamburgs there are about ninety pens, the largest class being Golden-pencils with twenty-six entries, and Silver-spangled with twenty entries. In Polands we find a vast improvement, for against ten pens of last season we find twenty-five this, the Blacks having nine out of them. Houdans make the largest class in the Show without the sale classes, for of this one breed there are close on fifty pens entered. While Crêves have twenty-one entries against fourteen in 1874. Malays, only seven pens are entered in 1875 against seventeen in 1874. The Fancy classes muster fairly. We find Americans have twenty-four entries, Silkies eleven, and the Variety class nine. Bantams promise to be good and the competition severe. There are forty pens of Game Bantams—seventeen of Blacks, eight of Bebrights, and fifteen in the Variety class. Waterfowl have good entries, and we hear the Indians (thank you, Mr. Bainsbury) have the largest class of all the varieties. The Sale classes number close on two hundred pens, and doubtless there will be many a plum to be picked out of that pudding.

Pigeon-fanciers have responded well to the extra money and cups given, for the entries are splendid in most classes, and many amateurs have sent here who do not send to other shows, which is a compliment to Mr. Salter's management. The proportion of entries in all classes is good, the Carriers, Antwarps, and Dragons being, perhaps, the best. We expect it will be a fine Show, and can confidently recommend visitors who have never been to Oxford to make this the occasion for doing so.

#### ALEXANDRA PALACE POULTRY SHOW.

THIS Exhibition opened at noon on Tuesday, and closes this evening. The quality of the birds is wonderfully good, and the arrangements extremely satisfactory. We shall content ourselves this week with giving a few general remarks, and next week shall furnish a full critical report of all the classes. The prize list itself, which we furnish, shows us that many of the good names have at last come to the front, and that the quality consequently is above all previous chicken shows of 1875.

*Dorkings* are very good, but with the exception of the Coloured make wretchedly small classes. In Coloured cockerels Mr. Hamilton's bird looks very well indeed. All the other winners are good, the fifth being a rose-comb, square in body, but crooked in toes. In pullets a large square bird is easily first, but her comb is not promising, though as yet quite unsprung. On the whole here is a good lot of pullets, and winning was not easy. In Silver-Greys the pullets are much the best class, and White pullets again are superior to the cockerels. Cuckoo are good, as nice a lot as we have seen for many a day, and winners seem well placed.

*Cochins* are not large classes, the Buffs, however, being much the best in numbers. We are afraid in these classes, as in many others, several hens are doing duty for pullets. It is a most disgraceful proceeding to win in this way, and we do beg Judges will particularly observe signs of this grievance and check it immediately. We will not here individualise suspicious cases, but if we see the birds so winning again we shall know how to proceed. We did not quite like some of the awards in the Cochins, but, perhaps, taking the lot there was not much wrong. The winning Buff pullet is very mottled in colour and high in comb, but also a fine-shaped bird and well stuffed. Cockerels are good, but we liked one or two birds quite as well as the winner. Partridges also good, the first cockerel especially fine. In Whites only the noticed birds in cockerels are superior, but the pullets are a fine lot. Black cockerels capital, the winner one of the best we ever saw. In pullets we liked Mr. Frank's highly-commanded bird much the best. The winner is red in neck, and had not a bit of bloom about her, besides being fearfully hocked; but we noticed a great deal of hock throughout all the Cochins classes.

*Brahmas* make very grand classes. The sale classes here, too, are especially noticeable for a good bird or two. Mr. Lingwood does walk his cockerels in; they are three grand birds, but our choice was for his third. Pullets are a good class, and it was a difficult one to judge. In Light cockerels we preferred the second for symmetry, or the fourth (Dean) for general shape; but the winner is a good bird. In pullets the winner is well cushioned and perfect in points.

*Spanish* are good in numbers. We are glad there are so many chickens about, for we hear there is a large class of them at Oxford. A smart pullet won the cup. Mr. Chilcott's cockerel is a good one, and of greater promise even yet for future shows.

*French* brought good birds. The cup cockerel one of the most stylish we ever saw. Pullets were also very good. Crêves mustered well, and we thought the winners well placed.

*Hamburgs* are magnificent: Messrs. Fielding, Beldon, and Duckworth send most splendid teams. Winning was not easy, but we should have liked to have altered, perhaps, one or two of the cards; but more of this next week.

*Game* come to the front well, and many good chickens make their debut here. The winning Black Red cockerel is a beauty, and the same exhibitor's Duckwing cockerel a striking bird. We are sorry to learn he is ill, and was unable to be present at the opening day of the autumn season.

*Malays* make two good classes, and we cannot understand their shortcomings at Oxford, from the numbers and quality here present.

*Polish* are three wonderful classes. The cup goes to White-crested Blacks against the other colours. The pullet is the best we ever saw; she is nothing but a picture, but the cockerel wants more time. In Golden the third pullet struck us as being the best in markings, and in Silvers we admired greatly the lacing on the second cockerel's wings, but it is a splendid class.

*Leghorns* form pretty classes, the cup going to a very smart brown pullet in perfect bloom. The winning birds appear to be all good.

*Silkies* are the best lot we ever saw together. We were pleased to see perfection at last in all points—colour, feathering, crest, and claws.

The Variety class is charming; fine Cuckoo Cochins first, unique and very elegant White Polands second, and Sultans third and fourth. The Sailing classes are very large, and the bargains seem to be numerous. We cannot go through them, however, this week.

*Bantams* mostly make good classes. We are delighted to find the Game so good, for we had feared they were rather going-off. Blacks also make a nice class, and in Bebrights the winning pens are perfect gems. In the Variety class White Rosecombs are first and second, and White-booted third.

*Waterfowl* come well to the front, Aylesburys and Rouens being extremely good. The Blacks are good in numbers, but we must defer further comments till next week, as when we reached them the light was gone, but the first-prize winners looked large; if they are good in colour we shall rejoice to think size and colour may at last go together. Variety Ducks are very beautiful, and were very difficult to judge, we should say.

*Geese* and *Turkeys* are splendid. We never wish to see a better pair of White Geese than the winners were. Turkeys were divided as to sexes, which seems a most proper plan, and to answer here as far as the entries are concerned.

One word before closing this week to congratulate very much the Treasurer and Secretaries on their Show, which is, we suppose, the largest maiden poultry show ever held, and seems a success in every possible way.

**TUMBLERS (Any other variety).**—Cock—1 and Cup, H. Yardley. 2, H. G. Hamcock. 3, R. O. Fielding. *Hen*, R. Fulton. T. W. Townson, J. Baker, E. Beckwith (3).

**ANTWERPS (Homing).**—1, Col. Hassard. 2 and 3, W. S. Marsh. 4, W. E. Tegemeier. *Hen*, W. E. Tegemeier, Capt. G. Edwards. c, J. Wright.

**ANY OTHER VARIETY.**—1, G. H. Gregory. 2, A. & W. H. Silvester. 3, J. W. Ludlow. *Hen*, R. Fulton, H. Yardley. *Hen*, G. Richardson, J. W. Ludlow, H. Dwyer.

**SELLING CLASS.—Single Bird.**—1, G. Kempton. 2, J. Nichols. 3, W. Osmond. 4, G. Murphy. *Hen*, H. M. Maynard. *Hen*, N. Bargent, D. Young, H. Jacob. L. Allen, W. Nottage, H. Simpson.

**SELLING CLASS.—Pair.**—1, H. M. Maynard. 2, G. P. Pointer. 3, G. J. Avenell. 4, W. Osmond. *Hen*, A. Ward, D. Young, G. P. Pointer, G. J. Avenell.

**SPECIAL FLYING CLASS FOR HOMING BIRDS.**—Cock or *Hen*.—1, 2, and 3, W. E. Tegemeier. 4, T. G. Ledger. 5 and 6, F. Lubbock. *Hen*, F. Lubbock (3), W. E. Tegemeier, H. W. Crosse (3). c, G. Cotton, Colonel Hassard, W. E. Wills (3).

**JUDGES.—Poultry:** Mr. J. Dixon, Mr. E. Hewitt, Mr. J. H. Smith, and Mr. R. Teebay. **Pigeons:** Mr. T. J. Charlton, Mr. F. Hequiant, Captain Heaton, and Mr. T. H. Ridpath. **Homing Antwerps:** Messrs. C. Mills and C. L. Sutherland.

## DORKING CUPS AT THE CRYSTAL PALACE SHOW.

In reply to inquiries about the Dorking cups at the forthcoming poultry show at the Crystal Palace, I beg to inform you there was a printer's error in the first few schedules sent out. The intention is for cock or hen in their respective classes. I will reply to numerous inquiries upon the Baroness Burdett Coutts' cups in your next issue.—F. CROOK.

## NORTHAMPTON SHOW.

THE fourth annual Show of the Northampton Ornithological Society was held in the spacious Corn Exchange, Northampton, on the 18th and 14th inst.

In Pigeons, Pouters, cocks headed the list, the special prize for the best bird in the Show going to the first, a showy White cock, which was however closely pressed by a Blue Pied, which was scarcely as forward; the third was a Red. In hens a smart Blue was first, and White second, and Blue third, and the whole class noticed. In Carriers, cocks, first was a capital Black; second a Dun, good in beak, but wanting in eye wattle; third also a Black. In hens, first and second were very good, but the rest poor. Young Carriers had but seven entries, first a Black, and second a Blue, but strong smart birds. In Barbs, first and second Blacks, and third Yellow. All cocks. Tumblers were—first a most extraordinary Kite, second an Almond, and third a Red Whole-feather; very good Almonds and Agates very highly commended. Owls were a very good and large class, the first going to a very small Blue Foreign, most perfect in skull; second to a Blue English; and third to a neat little White Foreign. Almost all the others were mentioned. Turbits another large class, was one of the best in the Show—first a splendid Silver, second a Blue, and third a Black. Eleven other pens noticed. Jacobins a fair class, first a Red, second White, and third Red. Dragons

had twenty-five entries, and was about the best class in the Show, and two extras were awarded. First a Yellow; second Blue; extra second Yellow, not quite in hard feather, but of grand colour; third Silver with black bars; and extra third a Grizzle. Twelve others noticed. Antwerps numbered thirty and were a very good class, the winners were birds it would be impossible to improve upon. First a Short-faced Silver Dun, which we think won the cup at Bingley; second a Short-faced Red Chequer; and third a Long-faced Silver Dun of this year. If we mistake not all hard-feathered short-winged birds, and many others noticed. The Variety class was an interesting one, almost every pen being worthy of a prize. First was a Black Trumpeter; second an Isabel; and third a Spangled Ice; very highly commended, and highly commended Grey Frillback, and true Pigmy White Pouters.

In Rabbits there were 124 entries in seven classes, and considering the amount offered we believe this to be an achievement altogether unprecedented, but the great point was the quality, which as a whole we have never seen surpassed. In Lops there were twelve entries, and with one pen empty, the measurement being something extraordinary, and with not the least stretching the following were the results—first Fawn Doe, 23½ by 5 inches, perfect in form, condition, and colour, but the right leg being a little crooked lost this the extra for the best in the Show; second a Fawn Buck, 22 by 4½, good in all points; and third, a Fawn Doe; very highly commended a Grey Doe, 22 by 4½, and Fawn-and-white, 22½ by 4½, and Fawn, 22½ by 4½, and a Tortoiseshell, 21 by 4½. All the rest measuring well up the standard lengths. Dutch, as a class, were the worst as regards quality, only a few coming up to the required standard; first was, however, one of the most handsome Tortoiseshells ever seen; second a Black, good but rather large; and third a Blue-and-white, nice and pretty correct, but not in as fine order as we have seen it. Angora was a capital class, not so much for size as for quality and quantity of wool, and there was scarcely a Rabbit unworthy of a position. Himalayans were a tough lot, and it was most difficult to determine among the first six and between the first two, the colour of tail had to decide the point. Almost every pen was noticed, as were the Silver-Greys, of which there were twenty-three, and scarcely one not good enough to win a prize, and of these twenty-one were noticed. First a doe of massive size, fine condition, and unbroken silvering, and of the light shade so common of late; this Rabbit took the extra also. Second also a doe, of a shade a little more to our taste, fuller of ticking, but a little darker on head; third a doe of the lighter shade, but not in the same fur; very highly commended a very large buck, but broken in coat; several others running close in quality. The Variety class contained some good ones. First a Silver Cream, perhaps the best ever shown; second a grand Belgian Hare; and third a Patagonian. Many capital Silver Creams and Hare Rabbits being also noticed. The Selling class was only a moderate one, although the winners were very good, the first being a nice Belgian Hare; second a Tortoiseshell, but very thin and low in condition; and third a Silver-Grey.

The Cage Birds, in point of number of entries, were about on a par with those exhibited the week previous in the north of England. As might have been expected, Norwich birds were more numerous here. There was a slight falling-off in Belgian and Yorkshire birds. Messrs. Provart & Willis of Norwich, the great guns, especially in the "clear" classes at the late Norwich Exhibition, put in an appearance with some of their showy high-coloured birds, with which they were pretty successful, defeating Mr. Adams and Mr. Atherton of Coventry, and likewise Messrs. Mackley of Norwich, each of whom had been successful at Darlington. Throughout the Norwich classes the Clear, Even-marked, and Ticked varieties were very good generally, and the prizewinners carefully selected. With the decisions little fault could be found, excepting a trifling blemish in the way of an even-marked specimen or two, such as a dark feather showing in the portion of the wing which should be clear or light, and in another instance an apparent deficiency of tail feathers. But the best should be the best at all times, and, to sum up the lot, we think the best were in their proper places. Crested Buffs (which far surpassed the Yellows) a very good class, so also were those for Silver-spangled Lizards, Cinnamons, and Mules. The first-prize Jonque Lizard was not our choice, being miserably deficient of good spangling, although good in form. British and foreign birds beyond an average kind. In the former class three capital Thrushes of the proper size, plumage, and condition were shown. Two in particular (231, first prize, and 280, v.e.c.), of which we could see little difference. To say that Mr. Wright's Thrush was not fully deserving of the honour of a first prize would be unjust on our part; but we cannot help remarking that an extra prize was due to Mr. Newbold's Thrush, a winner of several previous prizes, one amongst which was a first at the last Crystal Palace Bird Show, when a dozen birds competed in the class. Amongst the foreign birds were a couple of King Parrots, Grey and Green Parrots, Parakeets, Cockatoos, Love Birds, Java Sparrows, and a Madagascar Bishop. With

the awards we fully concurred. The King Parrot (261) won easy with as much ease as the Cockatoo (255) defeated the others. Still there was a third prize and an extra third awarded. The birds looked quite showy throughout the Corn Exchange, which is one of the best-adapted rooms in the kingdom, being light and the stages well set out by a Committee who deserve all praise for their endeavours to please. The catalogue was compiled in good order, issued and posted to the exhibitors the same evening, and the birds well looked after. Many sales were effected, some of the prize birds being quickly claimed. A special prize, a pencil case, given to the best bird in the first four classes, belonging to a member of the "Good Intent" Society, was awarded to Mr. Stageman's bird (40) in class 8. The prize of £1 for the greatest number of points in the Canary section of the Show was won by Mr. Adams of Coventry; and another prize of £1 for the best bird in the same section was awarded to Mr. Bunting's famous Goldfinch-and-Canary Buff Mule, the next strongest competitor to it being a Linnet-and-Canary Mule exhibited by Mr. Stevens.

## PIGEONS.

**POUTERS.**—Cock.—1 and Special, L. & W. Watkin, Northampton. 2, W. Nottage, Northampton. 3, J. Baker, Spring Grove, Kew Bridge. 4, C. Martin; Foster and Chambers. Hen.—1 and 2, W. Nottage. 2, L. & W. Watkin. 3, J. Baker. 4, C. Martin. 5, L. & W. Watkin.

**CARRIERS.**—Cock or Hen.—1, H. Yardley, Birmingham. 2, J. Baker. 3, W. Larkins, Henlow, Biggleswade. 4, W. J. Warhurst; J. Baker; W. J. Toon. 5, H. Parker; W. Nottage. Hen.—1, J. Baker. 2, W. Larkins. 3, G. Beasley, Rickmansworth. 4, H. Yardley.

**CARRIERS.**—Young Cock or Hen.—1, H. Simpson, Spalding. 2, J. Baker. 3, W. J. Toon, Kettering. 4, J. Baker; G. H. Pym. 5, G. H. Pym.

**BARRAS.**—Cock or Hen.—1, H. Yardley. 2, W. Larkins. 3 and 4, J. Baker. 5, C. A. P. Byford.

**TUMBLERS.**—Cock or Hen.—1 and 2, J. Baker. 3, W. Nottage. 4, A. & W. H. Silvester. 5, J. Baker; H. Yardley.

**OWLS.**—Cock or Hen.—1, J. Baker. 2, W. G. Henry, Sandymount, Co. Dublin. 3, T. Chambers, Northampton. 4, T. Chambers; J. Baker. 5, H. W. Webb; J. Barnes; W. Nottage; J. Baker; H. Yardley. 6, F. Siedle.

**TUMBLERS.**—Cock or Hen.—1, H. Yardley. 2, T. Homes, Lower Sydenham. 3, E. E. Horsfield, Grassendale Priory, Liverpool. 4, C. A. Ormer; J. Baker. 5, J. Cargill; R. Woods; C. W. Washbourne; J. Baker; A. & W. H. Silvester. 6, W. J. Warhurst; G. W. Dutton; J. Baker.

**JACOBIANS.**—Cock or Hen.—1, C. Martin, Kettering. 2, J. Baker. 3, T. W. Swallow, Northampton. 4, C. Martin. 5, F. Siedle; J. Baker.

**DRACOONS.**—Cock or Hen.—1, J. Baker. 2, H. Yardley. 3, A. McKennie, Liverpool. Extra 1 and 2, R. Woods, Mansfield. 4, J. Baker; A. McKennie; W. Smith. 5, R. Woods; W. G. Henry; Foster and Chambers; Griffin and Jones; A. McKennie; C. F. Herrieff; W. Larkins. 6, E. C. Jardine.

**ANTWERPS.**—Cock or Hen.—1, C. F. Copeman, Solihull, Warwick. 2, H. Cox, Smethwick. 3, O. F. Herrieff, Banbury. 4, H. Yardley; Miss M. A. Perrin; O. Gamon. 5, J. Hill; C. F. Herrieff; H. Yardley; C. Hillier; H. W. Weaving; A. McKennie; J. Kendrick; H. Cox; O. Gamon. 6, Griffin and Jones; Sorrag and Valters; H. Hill.

**ANY OTHER VARIETY.**—Cock or Hen.—1, J. Baker. 2 and 3, A. & W. H. Silvester, Sheffield. 4, J. Baker; H. W. Webb, Lower Sydenham. 5, W. Brown; H. Yardley; C. F. Herrieff; J. Baker; W. H. Crews; H. W. Webb. 6, F. Siedle.

**SELLING CLASS.**—Single Birds.—1 and 2, H. W. Webb. 3, W. Nottage. 4, W. Brown; Foster and Chambers; W. Nottage; T. Chambers, jun.; J. Barnes; J. Brown; C. Hillier; W. Larkins. 5, R. Woods; A. P. Byford; H. Simpson; C. E. Chavasse.

**SELLING CLASS.**—Pairs.—1 and 2, W. Nottage. 3, A. P. Byford, Ipswich. 4, W. G. Henry; T. Chambers, jun.; J. Baker. 5, W. G. Henry; O. E. Chavasse; Foster and Chambers; W. Brown.

## RABBITS.

**LOP-EARED.**—Buck or Doe.—1, T. Schofield, jun., Cheetham, Manchester. 2, J. Barker, Louth. 3, T. & E. J. Fell, Blackburn. 4, T. Lomath; H. Woods; T. Schofield, jun.; Mrs. H. Pickworth. 5, H. E. Jones; T. Green. 6, J. Bingham.

**DUPES.**—Buck or Doe.—1, F. Glover, Wellingsborough. 2, Mrs. H. Pickworth, Moulton Marsh, Spalding. 3, W. Doukin, Driffield. 4, Mrs. H. Pickworth; B. Greaves; J. G. Meadowcroft; Rev. T. O. Beasley. 5, Griffin and Jones; Master H. E. Johnson.

**ANGORA.**—Buck or Doe.—1, R. H. Swain, Heywood, Lancashire. 2, W. Welch, Northampton. 3 and 4, J. Martin, Kettering. 5, J. Martin; H. E. Gilbert; A. Farndon; S. M. Beasley. 6, W. G. Cross; W. M. A. Hames; T. & E. J. Fell; J. Hallas.

**HIMALAYAN.**—Buck or Doe.—1, Foster and Chambers, Northampton. 2, H. E. Gilbert. 3, J. Barker. 4, J. G. Meadowcroft; C. G. Mason. 5, H. E. Pilgrim; C. G. Millet; A. W. Whitehouse; T. Schofield, jun.; C. Tassell; J. Hallas. 6, J. James; J. G. Meadowcroft; J. Tebbutt; C. Tassell.

**SILVER-GREY.**—Buck or Doe.—1 and Special, J. Firth, Bramley, Leeds. 2, F. Purser, Bedford. 3, G. Johnson, Bedford. 4, T. Schofield; J. Tebbutt; J. Quick; F. Purser; E. B. Smith. 5, A. W. Whitehouse; J. G. Meadowcroft; B. Greaves; E. Ames; H. W. Wright; E. Robinson; R. H. Glew; W. Daniell. 6, E. Ames; E. Robinson.

**ANY OTHER VARIETY.**—Buck or Doe.—1, S. Ball, Bradford (Silver-Cream). 2, Rev. T. O. Beasley, Dallington, Northampton (Belgian Hare). 3, G. H. Robinson, Edenhurst, Sevenoak (Belgian Hare). 4, W. H. Crews (Belgian Hare); W. B. Smith (Silver-Cream); B. Greaves (Belgian Hare). 5, W. H. Crews (Belgian Hare); B. Greaves (Belgian Hare); J. Tebbutt (Belgian Hare). 6, A. W. Whitehouse (Belgian Hare); T. Schofield, jun. (Belgian Hare); J. Hallas (Belgian Hare); A. Skinner (Belgian Hare); S. H. Pilgrim (Belgian Hare); J. Tebbutt (Belgian Hare).

**SELLING CLASS.**—Buck or Doe.—1, Mrs. H. Pickworth. 2, T. Schofield, jun. 3, F. Purser. 4, J. Tebbutt; B. Greaves; H. E. Hallam. 5, B. Greaves; Rev. T. O. Beasley; J. C. Bamber; Mrs. Francis; J. Hallas; J. Bingham.

## OAGE BIRDS.

**NORWICH.**—Clear Jonque.—1 and 2, W. Willis & Provart, Helgham, Norwich. 3, J. Athersuch, Coventry. 4, J. Athersuch; G. & J. Mackley; J. Adams. 5, J. Adams. 6, G. Hobbs. Clear Buff.—1, 2 and Extra 3, Willis & Provart. 4, G. & J. Mackley, Norwich. 5, J. Adams; J. Athersuch. 6, Brown and Gayton. 7, G. Hobbs.

**NORWICH.**—Evenly-marked Jonque.—1 and 2, G. & J. Mackley. 3 and pencil case, J. Stageman, Northampton. 4, J. Athersuch; Martin & Griffin. 5, Moore & Wynn. Evenly-marked Buff.—1, J. Adams, Coventry. 2, Brown and Gayton, Northampton. 3, C. J. Salt, Burton-on-Trent. 4 and 5, G. & J. Mackley.

**NORWICH.**—Ticked or Unevenly-marked Jonque.—1 and 2, J. Athersuch. 3 and 4, J. Adams. 5, G. & J. Mackley. Ticked or Unevenly-marked Buff.—1, J. Adams. 2, J. Athersuch. 3, G. & J. Mackley. 4, Willis & Provart; G. & J. Mackley. 5, J. Adams; Willis & Provart; J. Athersuch. 6, Willis and Provart.

**NORWICH.**—Any variety Crested Jonque.—1, J. Torr, Derby. 2, G. Cox, Northampton. 3, F. Woodward, Litchurch, Derby. 4, C. Hillier. 5, G. & J. Mackley. 6, T. Wright. Any variety Crested Buff.—1, S. Stratford, Northamp-

ton. 2, F. Woodward. 3, G. Cox. 4, J. Athersuch; G. & J. Mackley. 5, G. & J. Mackley; J. Adams. 6, Martin & Griffin.

**BELGIAN.**—Clear, Ticked, or Variegated Yellow.—1 and 2, Withheld. 3, J. Horn, Armley, Leeds. 4, J. Horn; H. Wootton. Clear, Ticked, or Variegated Buff.—1 and 2, Withheld. 3 and 4, H. Davies, Wolverhampton.

**YORKSHIRE.**—Clear, Ticked, or Unevenly-marked Yellow.—1 and 2, Withheld. 3, J. Thackeray, Bradford. 4, J. Thackeray; L. Bell. Clear, Ticked, or Unevenly-marked Buff.—1 and 2, Thackeray. 3, Withheld. 4, E. Rhodes. 5, L. Bell. 6, G. & J. Mackley; T. Wright.

**YORKSHIRE.**—Evenly-marked Yellow or Buff.—1, Withheld. 2 and 3, J. Thackeray. 4 and 5, L. Bell, Dewsbury.

**LEICESTER.**—Golden-spangled.—1, J. Athersuch. 2, 3 and 4, S. Bunting, Derby. 5, R. Elcheie. Silver-spangled.—1, 2, and 3, R. Elcheie, Darlington. 4, S. Bunting. 5, S. Bunting; J. Athersuch. 6, J. Stevens.

**CINNAMON.**—Jonque.—1, J. Athersuch. 2 and 3, J. Adams. 4, T. Newbold, Brown & Gayton. 5, J. Stageman. 6, W. Elce. Buff.—1, 2, and 3, J. Adams. 4, W. Elce. 5, G. Cox. 6, J. Stageman.

**CINNAMON.**—Ticked or Broken, Jonque or Buff.—1 and 2, J. Adams. 3, J. Athersuch. 4, Moore & Wynn. 5, J. Seaton.

**CINNAMON.**—Evenly-marked or Variegated, Jonque or Buff, Plain or Crested.—1, L. Bell. 2 and 3, Brown & Gayton. 4, G. & J. Mackley. 5, W. Hayes; T. Townswood. 6, G. Golby.

**ANY OTHER VARIETY OF CANARY OR MULE NOT SPECIFIED.**—1, J. Stevens, Middlebrough (Linnet Mule). 2, W. Bowyer, Derby (Coppie). 3, E. Gilbert, Northampton (Linnet Mule). 4, G. B. Russell (Linnet Mule). 5, Martin and Griffin; S. Cook (Linnet Mule). 6, G. & J. Mackley (Lancashire Plain-head).

**GOLDFINCH MULE.**—Clear, Evenly-marked, or Variegated Jonque or Buff.—1, S. Bunting. 2 and 3, S. Bunting. 4, G. & J. Mackley. 5, G. B. Russell. 6, J. Horn.

**GOLDFINCH MULE.**—Dark Jonque or Buff.—1, J. Athersuch. 2 and 3, Moore & Wynn, Northampton. 4, G. & J. Mackley. 5, J. Stevens. 6, Brown & Gayton; G. Cox.

**BRITISH BIRDS.**—1, T. Wright, Northampton (Thrush). 2, W. Mead, Northampton (Hawk). 3, S. Abbott, Northampton (Jay). 4, T. Newbold (Thrush); W. Lonsdale (Starling). 5, J. Lacey (Thrush). 6, J. Horn.

**PARROTS, OR ANY OTHER VARIETY OF PARROT.**—Single or in Pairs.—1, S. Bunting (King Parrot). 2, W. L. Chapman, Northampton (Cockatoo). 3, W. Jeffrey, Northampton (Parrot). Extra 3, Martin & Griffin, Northampton (Cockatoo). 4, G. Sturges (Parakeet). 5, J. T. Gitch (Lovebird). 6, J. Trasher (Parrot).

**SELLING CLASS.**—1, L. Bell. 2, J. Athersuch. 3, W. Stringer, Atherstone. 4, T. Townswood, Middlebrough; E. Gilbert. 5, J. Athersuch; Willis and Provart; J. Middleton; Moore & Wynn. 6, J. Stageman; J. Athersuch; S. England; G. E. Russell; T. Newbold.

## SPECIAL PRIZES.

Prize for greatest number of points in Canary section, J. Adams, with twenty-one points.

Prize for best bird in the Canary section, S. Bunting.

Prize for greatest number of points in the Pigeon section, J. Baker, with twenty-five points.

Prize for the best pen in the Pigeon section, L. & W. Watkin.

Prize for the greatest number of points in the Rabbit section, Mrs. Pickworth and T. Schofield, jun., five points each.

Prize for best pen in the Rabbit section, J. Firth.

**JUDGES.**—Pigeons and Rabbits: Mr. E. Hutton, Pudsey. Cage

Birds: Mr. Walter, Winchester.

## THE JACOBIN.

I SCARCELY like to disagree with so genial and gentle a writer as "WILTSHIRE RECTOR," but in the true interest of the fancy I feel bound to do so.

In the first place I must differ as regards improvements of breed; this, I think, cannot be allowed. There are the points of a bird, the Jacobin for instance, truly laid down, and any deviation from them is a defect, and a judge would necessarily not place such an one first, nor ought he in my opinion to notice such birds, as it is by this means the true strains get gradually deteriorated, and quite a different kind of bird is substituted for the original. Now, as regards the Jacobin, the modern bird has scarcely one point in common with the original type. The head is different, the form, the frill, the carriage, and the marking; and some of them, instead of being improvements, are to me quite the other way. If one fancier fancies clear thighs, and another the mane, and so on, and shows them, by what rule are they to be judged? In my opinion only by the old standard of the true Jacobin, and by nothing else. A short time ago some fanciers tried to introduce pepper-throated Beards, and they gained some headway, until they found at the best shows not a bird was noticed; also white thighs were tried, but I am glad to find that is now abandoned for the whole colour. Make a new breed if you like, and lay down points to breed to; but when there is a bird of old standing, with all its qualities well defined, I cannot think it right to call a deviation from it improvement, and the judges at shows ought to mark their disapprobation of such by not awarding honours to them. By their not doing so the truly beautiful Jacobin has disappeared, and quite another thing substituted and shown in the Jacobin class.

I am rather surprised at "WILTSHIRE RECTOR," after enumerating the names of several well-known fanciers, saying that he has birds of their strains of various sizes, &c., which shows how good birds vary of the same variety. There is but one set of points of excellence in the Jacobin; no more. Then any other variety of Pigeon, and any birds that do not come up to them, are not good birds, be they bred by whomsoever they may. Again, as an artist, I differ with him when he says the high-out birds are not so beautiful as the low-out. With regard to the clear thighs, I believe my friend, the late and much-lamented Mr. Matthew Wicking, was one of the first to introduce them. Talking to me on the subject he said he did not consider it right, but as a fancy of his he would try and breed them so, and he did. Afterwards he told me he thought it a mistake, as they did not look so well. Again, as an artist my opinion is that the

white thighs are wrong, and do not give the balance to the long heavy frill that the solid colour does. Whoever laid the points for the Jacobin originally, in my opinion, well considered his subject, and I have often looked on the true birds and thought to myself that there was not a point I could alter for the better. It is quite different with the modern Jacobin, call it what you will, but not the true bird.

"WILTSHIRE RACTOR" says that the thighs are seldom so wholly dark, but that is no proof that they ought not to be. As regards the rose, it could not exist in the true Jacobin; nor the mane, because the division of the frill would not be of the length and form that it ought to be. I am sure that "WILTSHIRE RACTOR" will pardon any difference of opinion from him on my part, but I seriously think that he has, by his suggestion of improved breed, opened the gate to let in a flood of innovations, of which I am very sorry to say there are far too many already, and unless the rules and points laid down by old and valued authorities be strictly adhered to there is an end to all true breeds and good and proper judging.—HARRISON WHEAT.

### BEEs TWENTY DAYS HATCHING FROM THE EGG.

SOME time ago there was a controversy in this Journal between Mr. Pettigrew and Mr. Lowe on the question as to how long it takes for the development of the perfect insect (worker bee) from the laying of the egg; Mr. Lowe stating and proving from his own experience that such development takes place in twenty days—in other words, that the insect will issue from the cell as a rule on the twentieth day after the laying of the egg. Mr. Pettigrew, on the other hand, maintained that the rule required twenty-one days to elapse before the said development takes place, winding up with the statement that he "preferred his own and others' statement of days to Mr. Lowe's twenty days." Allow me to state my own recent experience in this matter. I do so simply in the interest of exact truth in a matter of some importance, not only because it is useful to the practical apiculturist to know the fact, but in defence of all the great masters in bee knowledge from Haber downwards.

On the 14th of May one of my servants reported to me that my bees were swarming. On going into the garden I became aware that a deserted hive, out of which the bees had died gradually a month or six weeks before, was being taken possession of by the said swarm. I soon found that it had come from a distance, as none of my own hives had swarmed; and, moreover, the bees were of the common English sort, which I have long disused in my apiary. Circumstances led me to examine the progress of this swarm, for they had great difficulty with the combs, many of which they carried away piecemeal, building fresh combs in their stead. My curiosity also was aroused on this very question, as I fortunately recollected the somewhat warm debate in your columns on this point. As the day approached I was therefore on the look-out, and sure enough on the morning of the twentieth day there were several young bees walking on the edges of the combs, pale-coloured and preening their wings as they usually do under the circumstances. I find the following note in my diary on the 3rd of June—"Saw several young bees to-day in Tasm. hive; consequently they must have been developed from the laying of the egg in less than twenty days complete."—B. & W.

**HUMBLE BEES FOR NEW ZEALAND.**—An interesting experiment, says the *Daily News*, is being made in the shipment of two nests of humble bees, which have just left Plymouth for Canterbury, New Zealand. The principal object aimed at in the introduction of these insects into the Antipodes is the fertilisation of the common clover, the pollen of which the common bee is generally unable to collect, while the humble bee, having a larger proboscis and being much stronger, is able to reach sufficiently deep into the flower to collect the fertilising dust. It is hoped that by this means the plant will be more generally fertilised, and its cultivation largely extended in the colony. The bees which have just left England for the Antipodes were in two separate nests, which had been procured by Mr. Frank Buckland, and packed in a suitable box where they were supplied with everything necessary for the voyage, including honey, farina, water, &c. They are very fine specimens of the humble bee. The exact number is not known, as many of the eggs are not yet hatched. They are placed under the care of Mr. John Hall, a member of the Council of New Zealand, who takes a stock of ice for the purpose of keeping down the temperature of the nests while passing through the tropics.

### OUR LETTER BOX.

**BUCKWHEAT FOR PIGEONS (E. B. T.).**—Buckwheat is not good as sole food for Pigeons. They soon tire of it. It is too fattening, and is bad for plumage, making the feathers very soft.

**BLACK BANTAM COCK'S COMB (J. T.).**—If the Bantam cock be exhibited

as a Black Bantam then it should have a rose comb, but if as a Game Bantam, and undubbed, it must have a single one. An ordinary Black Bantam cock should have a double comb to be a favourable or a high-class specimen of the breed.

**GIDDINESS IN FOWLS (F. H.).**—Bled by opening a large vein under the wing; pour cold water on the head; feed less and on moist food, and give abundance of lettuce leaves.

**DRAKE MOULTING (Subscriber).**—There is unnatural heat about the drake. You must rub the bare spots with citrine ointment, and discontinue all stimulating food. Confine yourself to that which a bird finds in a natural state. Oatmeal, bran, and whole oats are all good food. If the bird is in confinement give him daily a large sod of growing grass, cut with the earth, and put in the vessel containing his food, just covering it with water. If you will do this and confine him to the food we have mentioned, we believe the bird will recover and do well.

**TURKEY'S LEGS WEAKE (L. P.).**—It is not uncommon for Turkeys to fall off when the weather changes and the mornings and evenings are colder, but we have no hope of Turkeys doing well where the flooring of their house is of stone. It would make matters worse if you put boards over the stone. Take the stones up, and ram in earth mixed with chalk. Put on this an inch or two of road grit. Being under cover this is always dry, and affords healthy and useful picking. When the white frosts appear it is good to keep them confined till the sun is up, unless they are very forward birds. We do not approve of "hen spices." The natural food is good enough for any description of poultry, and they always did well upon it. In most other respects your feeding is good. We cannot help thinking that your mode of giving it is wrong. You say they always have food by them. This would imply it is constantly renewed. It must then become sour, and the birds take a dislike to it. To make very large and fat birds they should be fed three times per day, but the trough should be empty after every meal, and carefully cleaned. The feeder will soon ascertain how much they eat for a meal. Discontinue the bran. If you can substitute ground oats for barley-meal do so. Crooked breasts are often hereditary, when they are not they are the result of weakness. Their legs are too weak to hold them on the perch. Do you want change of blood? We never meet with a crooked-breasted Pheasant.

**ELEMENTARY BOOKS (An Aspirant).**—You cannot well go wrong in commencing to study physics. Since the days of our youth Chambers, Pimcock, Cassell, and many other firms have published educational courses containing all you need at first. From any catalogue of scientific works you may select what will suit you. Professor Beattie's *Alphabets*, published forty years ago or more, were of service to us. Read well every book, and master the elements of every branch as you proceed.

**FEEDING BEES (A. de C. B.).**—September is the time for autumn feeding, but by giving warm syrup to bees now they will store it up. The sooner and faster it is given to them the better. When bees are much abroad feeding should be done after sunset, but as they are beginning to sit quietly amongst their combs you may feed during the day as well as at night. As you have no feeding instruments of any kind, your better way will be to use dripping tins or soup plates. These should be filled with syrup, covered with chips of wood or straw, and placed on the boards inside your hives. If the combs touch the syrup no harm will be done. If the combs rest on the edges of the tins or plates raise the hives a little by ekes. You may turn up your hives and examine them internally at any time without injury to the bees. The hive that fell off the stool should be examined to see if any of its combs have been shaken out of place.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

- 13th.—Hazy and cold morning; showers in the forenoon; sunny at 1 P.M. and during the rest of the day. Lunar halo at night.  
 14th.—Fine morning and tolerably fair till noon, then rain; showery the remainder of the day, and heavy at night.  
 15th.—Very fine morning and till after 4 P.M., then raining for an hour or two, but fine after.  
 16th.—Fine all day, but rather foggy in evening and during the night.  
 17th.—Fair but hazy early, clearing off about noon, and fine day after.  
 18th.—Fine morning; rather cloudy after 3 P.M.; rain at 9 P.M., and heavy in the night.  
 19th.—Very dull early; showery and dull all day; rain at night.  
 Temperature generally about 4° below last week, dull Novemberish weather, with much rain on Monday and Tuesday.—G. J. SYMONS.

### COVENT GARDEN MARKET.—OCTOBER 20.

A good supply of best fruits has kept prices much the same, but common sorts of Apples cannot be cleared except at a very low figure, owing to the large quantities of windfalls that have reached the market during the week. Imported fruits consist of Hamburg, Almetra, and Sweetwater Grapes; Duchesse d'Angoulême, Cravanne, and Beurré Diel Pears; also some very good samples of Dutch Peaches.

From observations taken near London during forty-three years, the average day temperature of the week is 54.2°; and its night temperature 37.0°.

## NOTES ON THIS YEAR'S FRUIT CROPS.

NE of the most remarkable things in connection with the present year is that while it has been one of the coldest and dullest on record, it has at the same time been one of the most fruitful, and outdoor fruits, with the exception of Pears, have been good as well as plentiful.

Peaches, Nectarines, and Figs, which usually do not flourish here, have all been abundant. I have still (October 20) some fine fruit of Walburton and Late Admirable Peaches on the trees. Plums on walls have been abundant, and exceedingly fine in appearance and flavour. Coe's Golden Drop, now hanging on the trees, is as good as I ever tasted it. Imperatrice is not quite so good as it is sometimes. Plums always do well in our heavy moist soil, provided the blossoms are not cut off by the frost, and this year being moister than usual they have done proportionately better. They are also in a very promising condition for the coming season. I wish I could say the same of the Red and White Currants. We had abundance of fruit, and that for preserving and culinary purposes in the earlier part of the season was good, but towards the end of August the fruit remaining on the bushes began to shrivel; most of the foliage also dropped off soon after, leaving the bushes almost bare, and with small unripe wood. I do not think they will ever recover their former luxuriance. The only chance I have with them is to prune-back to the wood which is ripe, and in most cases that will be to the growth of last year. I am glad to say I have one kind which has withstood the cold soil and cold atmosphere, and has kept its leaves to the present time and ripened its wood—it is that known as Raby Castle; and I need not say that for the future all other Reds, excepting a few of an earlier kind to be planted on lighter soil, will have to give way to this one. Perhaps it might not succeed so well on a light soil; of that I have no experience, but I recommend those having a cold heavy soil to give a trial to Raby Castle.

Black Currants have done very well; they like moisture. Lee's Prolific is as superior to other Black Currants as the Rough Red Gooseberry is to the Roaring Lion—nay, more so, for it has both size and quality to recommend it; it has a sweet and delicious flavour altogether different from other Black Currants, and is quite fit for any dessert table. I do not know if it is superior to others for cooking purposes; for the best-flavoured fruits are not always the best for cooking, the action of the fire changes their character considerably, and they often only deserve a second-class place in the kitchen and still-room. This is notably the case with Strawberries, the old Grove End Scarlet being when raw a very inferior fruit, but cooked in any way, there is no other Strawberry with which I am acquainted half so good either in appearance or flavour.

Gooseberries have done well, especially Warrington. I should be glad if some one would recommend a light-

coloured Gooseberry of good appearance and flavour which will keep to the end of September or later. Any other colour than red will do.

Apples are abundant, and where they were severely thinned are fine, otherwise they are small and worthless. There is no dessert Apple in its season—early autumn—to be compared with the Kerry Pippin. At the present time King of the Pippins is the best I have.

Pears are neither good nor abundant. Jargonelle, Williams' Bon Chrétien, Fondante d'Automne, Suffolk Thorn, and Beurré Hardy have been fairly good in quality; the last named only remained in condition five days. Thompson's, which was so good last year, is this season so spotted as to be unfit for table; still, its flavour is very good. Marie Louise from a south wall was bitter and useless, and from an east wall and standard it is very little better. Hason's Incomparable from a south wall has no flavour whatever; but Van Mons Léon Leclerc from the same position promises to be, as it always is, A1.

The season, too, has had its effect on indoor fruits. Good Melons with me have not been plentiful; they have been thin and light in weight, and not up to the usual quality in flavour. The only kind tolerated here is Meredith's Cashmere, and it, perhaps more than any other Melon, requires a good season as well as good cultivation.

My usual practice with Muscats and other winter Grapes has had to be departed from, or I should not have had the wood ripened satisfactorily. In ordinary seasons if asked at what temperature I kept my Vines I could answer, From 50° to 95°; but as the day temperature very rarely reached the higher figure this season, I found it advisable to keep a higher night temperature. It takes a certain mean temperature to ripen Grapes and Vines, and if it can be kept up by solar heat so much the better for the pocket and the health of the plants; but when it is not produced naturally it must be had in another way. It is not a few degrees higher or lower occasionally that is of so much consequence as is the average temperature: 55° for a limited time will not harm the tenderest variety of Grape in cultivation, neither will 95° by solar heat when the ventilation is skilfully attended to; but either of these extreme temperatures kept continually would ruin both Grapes and Vines. It does no harm for a few hours in the day to maintain a high temperature when there is abundance of light; and, on the other hand, the night temperature ought never to be sufficiently high to excite the plants; but, as I have already said, a certain average temperature must be maintained, and if the sun fails to do it, then it must be produced by the aid of fuel. In practice this season I have found it the most economical to keep a rather higher night temperature than usual and give less ventilation by day—in other words, to keep on forcing all the summer.

Where this forcing has not been done it would be advisable even now to apply fire heat, with air, where Vines have not lost their foliage, to assist the maturation of the wood. In the case of the many amateurs and

others who at this season pot-up *Pelargoniums*, &c., and place them in their vineries, the extra heat given to the Vines will be beneficial also in assisting the re-establishment of the newly-potted plants.—WILLIAM TAYLOR, *Longleat*.

## PLANTS FOR CUT FLOWERS AND SPRAYS.

No. 6.

**VALLOTA PURPUREA.**—The Scarborough Lily is so named from association with Lord Scarborough, and not from any reference to the well-known watering place of that name, as might be concluded from an observation I heard the other day—viz., “the Vallota did remarkably well on the east coast,” and I would beg to add in every greenhouse in any part of the kingdom. It is the finest of all greenhouse bulbs, and very free-blooming, doing also very well as a window plant. The flowers, as everyone knows, are bright deep scarlet, and when going-off have a tinge of purple; hence, perhaps, its name. For vase-filling for table purposes in its season it is matchless, the deep yellow anthers contrasting well with the petal-colouring. By itself, or a ground of it studded with white *Liliums* is superb, or a margin of *Lapageria rosea* blooms alternating with the white variety (*L. alba*) and filled-up with Vallota, and a few white *Lilium* blooms interspersed, and moderate green used, not to hide but to relieve, a charming vase is had for table. It flowers in a greenhouse at the close of August and early in September; and plants placed outdoors in an open situation will flower at the close of September, and may then be moved under glass. In any light airy position—in a pit or greenhouse from which frost is excluded, or a room window—it is quite at home, requiring abundant supplies of water when in growth, which will be during the spring and early summer months, and after June water need only be given to keep the leaves from flagging, but they are not to be dried-off at any time, the plant being strictly evergreen. Potting may be done in November, or in February or March, potting with the ball entire, or removing only any loose soil, and not removing any offsets unless stock is wanted, and giving no larger size of pot than to admit a little fresh soil all around. A compost of turfy loam, with a third of leaf soil, with or without a fourth of old cow dung will grow it well, affording good drainage. The variety *eximia* is considered finer, and major has a stronger habit, large flowers, darker foliage, has a white throat, and is paler in colour.

**JACOBZAN LILY** (*Sprekelia formosissima*).—This plant flowers in early summer, and by introducing it to gentle heat from January to March flowers may be had successively up to those flowering in the greenhouse. If the bulbs are dried their after well-doing is best secured by affording bottom heat after potting or repotting, as some do before starting, for though they will flower the leaf-growth is poor, and the after-flowering is meagre until the plants recover vigour. They are best potted when in full growth or some time after flowering, well watering until the growth is complete, and then only to keep from flagging, withholding water altogether when the leaves turn yellow. Half a dozen or more bulbs may be grown in a 6-inch pot. Good turfy loam with a third of leaf soil and a little old cow dung will grow them perfectly. Keep the plants in a greenhouse during the winter, not watering until the flower scapes appear. In summer a cold pit is a suitable place for them, but I am informed that in a well-drained soil with protective material in severe weather that this Lily makes a splendid outdoor display. I can remember its being grown in a Pine stove, and flowering in April.

**CRINUMS.**—*Crinum capense alba* and its variety *rosea* have funnel-shaped flowers in large umbels; the flowers are also large individually, and very sweet. In a greenhouse, where they want plenty of light, they flower in April or May, and outdoors later. The plants require an abundant supply of water during growth, and after that is complete gradually reduce it; none to be given when at rest, only the leaves are not to be allowed to flag. A well-drained soil outdoors is most suitable, and a sheltered position. *C. amabile* is a stove subject and grand, having twenty to thirty large rosy flowers on a scape 8 to 4 feet high, the tube 6 inches long, and lobes as long as the tube. *C. asiaticum* has white flowers, twenty or more on a scape. *C. americanum* has also white flowers; they are all highly but delicately fragrant, and require a stove, as do *C. zeylanicum*, *C. seabrum*, and *C. Makoyanum*. All have a grandeur about them for cutting not found out of the *Amaryllids*. *C. Herbertianum* is a hybrid between *seabrum* and *capense*, blush with red stripes, and requires a greenhouse; also *C. riparium*,

purple; and *C. aquaticum*, rosy red, a semiaquatic, which needs to be in a pan of water during growth.

All *Crinums* require turfy yellow loam with a fourth of cow dung or a third of leaf soil, and good drainage, as during growth the watering can hardly be too abundant. To keeping at great distances from the glass in shade, making no difference between the growing and resting period in watering—regular waterings being abominable treatment—is to be attributed the indifferent flowering of this family; but with very free watering during growth, enjoying full exposure to light, and with a drier and warmer atmosphere when maturing and at rest, they flower freely and are plants of great beauty.—G. ABBEY.

## FRUIT-TREE PLANTING.

WHAT should I plant? When should I plant? How should I plant? Here are three plain questions to which it is highly important that equally plain answers should be given. It is by no means an easy matter to do this so as to meet the requirements of every class. Some wish for novelties, others for very early or late kinds; peculiarities of flavour and of form also find numerous advocates. Then, too, an elaborate explanation of the details of planting is apt to mislead and puzzle the uninitiated, frequently causing considerable waste of time, labour, and capital. The answers, therefore, must be simple, clear, and so comprehensive as to afford some hints for the guidance of all. Let us take the questions as they stand.

What should I plant?

1. For the supply of a large establishment. Enough of all kinds that are of a free vigorous growth, robust hardy constitution, and very prolific, including sorts which range from the earliest to the latest, so as to afford an abundant supply throughout the season. If there are two varieties with fruit bearing a close resemblance, do not hastily discard either of them; they are quite certain to differ somewhat in some essential point, apparently so trifling as to receive very little attention till some peculiarities of weather affect them for good or evil. To these such other varieties should be added as produce fruit of high excellence under favourable conditions, but which are so liable to suffer from unkindly seasons as to be unsuitable for gardens when to economise space is an object—delicate kinds, in fact, requiring more than ordinary cultural skill and care in their management.

2. For gardens of medium size. There must be no speculative work here. Every tree must be of some well-tried kind of sterling merit, and must form a link in that successive seasonable supply which it is so desirable to maintain without any failure.

3. For a small garden. A few very select and choice varieties coming to perfection in mid-season rather than very late or early, so as to ensure an annual supply so far as may be.

When should I plant? As soon as possible after the trees have shed their leaves for choice, and at any time during November and the two following months. Planting may also be done in February and March, but a season's growth is then endangered, and often lost—a serious matter in fruit-culture, and it is only upon an emergency that such late planting should be practised. November is undoubtedly the best month of the twelve for tree-planting; all growth has then ceased, the wood is matured, and the entire system is at rest. Much anxiety and watching is also avoided by planting early. Fine open weather and soil in a suitable condition should be made the most of. A single opportunity neglected now may lead to failure. Stern winter, with its stormy alternations and frost and snow, is approaching us; we cannot plant in sodden soil, and may have to wait till the sap is in motion and the pressure of spring work is upon us, and then the planting will be done with a rush, and the entire affair prove unsatisfactory.

How should I plant? Make the holes deep and wide enough for every root to be spread out without any twisting or cramping; cut off bruised roots and the ragged ends of any that are broken; pack the soil gently yet firmly among the roots, treading the surface well after all is covered, but avoid hard stamping, bruises from tools, or any similar rough practices. Careless men may often be seen trying to force a badly planted tree into an erect position by pushing and stamping, to its great risk and frequent damage. Do not bury the stems; many a valuable tree is lost through deep planting; 4 inches of soil is an ample covering for the roots. As a rule, the base of a newly planted tree should always be slightly elevated above the common level; some settlement always follows the planting, however closely the soil may have been pressed.

Let not beginners be misled by my details of planting given on page 355, and imagine such an elaborate and costly method of preparing the stations to be always necessary. Happily, such difficulties are the exception and, not the rule. In the majority of gardens no special preparation is requisite. Where other trees flourish and vegetables grow luxuriantly fruit trees may also be expected to answer thoroughly well. The fortunate owners of such soil can well afford a meed of pity for those of us whose lines have not fallen in such pleasant places.

Never suffer a freshly planted tree to be rocked by the wind; if you do there is great risk of loosening it. The top, acting like a lever, loosens the roots from that firm pressure of the soil which is of such vital importance. I attribute much of my success with young fruit trees to a strict attention to securing every tree with wires or stakes as it is planted, making that a part of the process of planting to be done before leaving the tree.

I append a short list of the best kinds of fruit, and hope to describe them at length in some future papers.

## PEACHES.

## HERBACEOUS PLANTS FOR BEDDING.

If anyone thinks that the herbaceous plants mentioned by "M. H."—pretty and useful as they are—can last under any treatment so as to bed with Geraniums, they will be disappointed. Perennials are very well in borders specially prepared, and every garden of any size ought to have a perennial or hardy herbaceous mixed border; but, do what one may, it is difficult, or impossible, to obtain a sufficient succession of bloom to make any continuous display. Amongst the best plants are Phloxes and Pentstemons, and where the position admits of it recourse must be had to sub-tropical-foliaged plants, as Cannas, variegated Maize, Ricinus, Giant Hemp, &c. These four I name have done well with me this year. Gladioli do well too in mixed borders. I can especially recommend them to be used in Rose beds, where plants are grown on the Manetti and where the soil is not too strong.

While on the subject of Gladioli I am ready to back out "D., Deal," if my opinion is worth anything. I do not think the Gladioli will degenerate under proper cultivation in good soil. We must remember a fresh corm is made every year, and when the soil suits, over-blooming will not affect the next corm.

Those bulbs I left in the ground all last winter gave me far finer spikes than those taken up, or than a hundred named sorts sent me by Mr. Kelway.—P.

**FROST IN ABERDEENSHIRE.**—In looking over the "Doings" in the Journal I was surprised to read, "The thermometer (at Ifford) has not yet fallen below 45° at night." We cannot say the same here (in Aberdeenshire), for on the nights of the 11th and 12th we had 6° and 7° of frost. Dahlias, Marigolds, &c., are completely destroyed. Mr. Douglas also states that soot prevents worms going into pots, being obnoxious to them. That is worth knowing; but I think worms are often introduced

unawares with the compost in the operation of potting. Then when their effects become visible, the question is, What is the best way to get rid of them? I shall be obliged by an answer to this query in your correspondents' column.—J. H., Logie Mar, Tarland, Aberdeenshire.

## INDELIBLE WRITING ON TALLIES.

THERE are few things more annoying to anyone who cares for the names of his plants and fruits than to find these obliterated by the weather, when, unless he be familiar with their faces, he is left to the only alternative of having to endeavour to rediscover their identities, which is often a matter of no slight difficulty, as well as uncertainty in the end.

Many years ago, for the double purpose of recreation and health by having a half-hour's fresh air once or twice in the day, and for obtaining cut flowers for the house, I purchased a small garden just outside the city walls, and about six minutes' walk from where I reside; but on looking over its contents I was very much disappointed in finding that in most instances the names were absent. In many cases the nurseryman's wooden label remained, although all trace of the names had ceased to exist, and it immediately suggested itself that had these been varnished while they were recent, in all probability the writing would be as permanent as the wooden tally itself.

In the re-arrangement of planting it was decided to put in several dozens more of fruit trees and bushes, and to have recourse to a plan of putting the above idea into practice; and I herewith enclose one of the varnished labels which has been out in all weathers for over a dozen years, and so far as its legibility is concerned there is little doubt but that it would have lasted as many more years, or even longer. I enclose also another which appears to have escaped the varnishing process, and in which the name is only just decipherable by close inspection. These, being cut out of sheet zinc, presented some difficulty as to the safest means of suspension, for neither iron nor copper wire were admissible on account of the galvanic corrosion, which would soon have caused them to fall; hence lead being contained in zinc as an alloy to render it capable of being rolled out, this was first adopted; but on the first high wind they were broken, or rather cut from their moorings and scattered far and wide from their places. Then, as the least of the evils, galvanised wire was employed, and its galvanic effects may be seen on the labels now sent.

Un glazed earthenware labels were next tried, but it seemed to be impossible to find any means of preventing the writing being washed off by the rain, and these, therefore, were soon discarded, going back to the old wooden strips fastened with thin copper wire as the most reliable after all. In preparing these labels, however, there are ways and ways, and it is not paint that should be used, but white lead of which paint is made. The easiest way of proceeding will be found to be as follows. Have a pennyworth of the best ground white lead tied up tightly into a ball in a piece of damp bladder or gut-skin; then insert a tinsack or very small flat-headed nail, which is to be replaced again as a stopper, into the shoulder by the side of the neck, and this, when drawn out, suffers a little of the lead to ooze out after it, which may be rubbed on to the prepared side of the tally with the end of the finger or a piece of dry sponge or lint, finishing it by writing the name with a soft black or BB twopenny drawing pencil into the wet surface. It is best to wire the labels first, and they may then be attached at once so as to dry on the plant. The most convenient arrangement, however, where a little more cost is not an object, is to procure a fourpenny tube of "flake white" as sold by stationers and artists' colourmen, as this is both clearer and a much better colour, and which is less liable to discolour by age, and is really but a mere trifle more expensive than the former plan. With respect to the varnishing this need not be attended to at once, but may be done any time within the next few months, choosing a dry season and a still day for the operation. Having provided two 1-oz., long, wide-mouthed phials with good corks, let one be half filled with copal, carriage, or quick-drying oak varnish, or such as may be obtained of almost any house painter, and the other with spirits of turpentine. Next procure a small hog's-hair brush that will go freely into the mouth of these bottles, or an artist's flat hog's-hair if it can be obtained. By having the phials only half full they may be suspended to the coat button with little fear of spilling, and will be easy to get at. If the brush becomes clogged it may be rinsed in the turpentine, otherwise the latter will only be wanted to wash the brush in after using, so as to

preserve it for another time, and may therefore be left indoors for safety.

For permanent pot-markers sheet zinc is unquestionably unequalled, and by being varnished it may be kept in very presentable condition for any length of time. The proper ink for writing on zinc is nitro-muriate of platinum, which produces a jet-black indelible stain. This preparation is easily made, and at very little cost. Procure an ounce stoppered phial, into which have two pennyworth, or half an ounce, of nitro-muriatic acid (composed of two parts muriatic to one of nitric), which may be obtained of any chemist. Next obtain from the gunsmith an old platinum touch-hole, which may be had for a few pence; then putting the latter in the acid and leaving out the stopper, set the phial in the sun or else upon hot sand until the acid has assumed a deep, rich, brown tint, or that the metal has ceased to give off bubbles of gas from the acid becoming a saturated solution. A few drops of this should now be added to a little water and tried with a quill pen, adding drop by drop until a sufficient blackness is produced. When using, great care must be taken to wash the writing thoroughly in plenty of water immediately it has blackened, and then it should be wiped quite dry and varnished as soon afterwards as possible.—W. KENCZLY BRIDGMAN, *Norwich*.

### WASPS AND TOMATOES—ONIONS AND CARROT GRUB—FLIES AND PLANTS IN ROOMS.

"D., Deal," asks, page 313, whether anyone has experience of the influence of Tomato plants in houses keeping away wasps. I have a row of Tomato plants in pots the whole length of two Peach houses, and any day for weeks, until within the last few days (the wasps having disappeared from the cold and wet, except a few queens which are seeking winter quarters) several of these useful as well as destructive creatures might be seen hunting for prey upon the Peach tree leaves, the trees happening to have an attack of scale, and upon the secretion of those pests the wasps and bluebottle flies feed greedily. Into the vineries the wasps do not come, at least for the last six years I have not had to take any measures to keep them from the Grapes, as they have not interfered with more than a cracked berry, and that rarely, and though Tomatoes were grown in the vineries, so that my experience points to the inutility of Tomatoes as a preventive of a wasp invasion.

For years I have not had a Carrot free from the grub; and as it was stated in "our Journal" some time ago that sowing Onions along with the Carrots was a safeguard, I gave it a trial, and have to acknowledge a more complete failure of the Carrots from grub with the Onions than when the Carrots were sown and grown without the Onions. I know certain plants never are attacked by insects of any kind, some plants by certain kinds of insects only; and I have found also that if you will train a *Stephanotis* up the same rafter with a *Clerodendron Balfourii*, that though both the plants have their shoots intertwined, the mealy bug and scale will thrive amazingly upon the *Stephanotis*. It was the same with the Carrots. Even where the Onions touched the Carrots the latter succumbed to the grubs.

Then I read in the newspapers how somebody found flies frequent a room when a box of plants—*Geraniums*, *Calceolarias*, and the like—were withdrawn, and when replaced in the window the flies disappeared. I remember hanging-up paper cages to attract the flies from the walls, the windows being full of plants—*Geraniums*, *Fuchsias*, and other plants. Experience tells me that insect attacks are not prevented by the presence of "strong-smelling" plants, or those upon which insects do not feed in proximity or in contact with those affording them subsistence.—G. ABBEY.

### PIERIS BRASSICÆ, AND MICROGASTER GLOMERATUS.

In some of the suburban districts the larvæ of *P. Brassicæ* (Large White Garden Butterfly) have been exceedingly numerous this season, but an effectual check to their development has been given by their familiar parasite. Some walls and palings to which the larvæ have retreated for pupation scarcely furnish one healthy pupa in a dozen, the rest having been punctured. A correspondent of the "Entomologist" appeals to naturalists to furnish him with pupa of *Microgaster* (an Ichneumon fly), so that the parasite may be freely introduced

into America, where the genus *Pieris* has been exceedingly destructive. I don't know how far we are justified in helping on this exportation. There is such a thing as "robbing Peter to pay Paul," and I fancy we want all the *Microgasters* ourselves at present. Has it ever been observed by the readers of this Journal that usually there is not an abundance in the same year of *P. Brassicæ* and *Baps*?—J. R. S. C.

[The white garden butterflies are by some entomologists retained in the genus *Pontia*.]

### CARRION FOR VINE BORDERS.

I HAVE read "INQUIRER's" remarks concerning the above practice, and feel rather pleased than otherwise that the question is once more mooted, because there are some employers, and even their gardeners, who have yet an idea that this burying of carrion in Vine borders is the one essential point to successful Grape culture. To my thinking, combined with some experience in the matter, nothing can be more adverse to the requirements of a Vine than to place such an unnatural substance in connection with the soil, and expect that the roots of a Vine will thrive in it. It is no doubt true that carrion may be buried at the bottom of a deep border when young Vines are planted, so that by the time the roots reach it decomposition will have done its work so efficiently as to make the carrion like soil itself. Even then it will have had its effect upon the soil for some distance around it, and through its action it will be a sour soddened mass from putrefied matter, that no roots, even as vigorous as are those of the Vine, can ramify in it to the benefit of the plant that receives its sustenance from them; and it may be that if the Vine is strong there will be no perceptible effect upon the condition of the growth, from the fact that if the Vine has been planted some years it will have roots elsewhere, so that its vigour may be maintained, and no check become apparent. I will relate my experience in the matter.

At the first place I took as head gardener there were some vineries newly built, and some Vines planted in newly and expensively made borders. I took the place on the 21st of March, and the Vines were planted the year previous. They were just breaking into growth, and apparently very promising, but to my surprise the Vines in the middle vinery of the three turned yellow in the leaf in the month of June. They flagged under the power of the sun, and made no progress as did the others in the other houses. I was puzzled to give my employer a reason for it, until I asked him how the borders were made, and during the conversation it came out that five pigs had been buried whole in this very border. This announcement was quite sufficient to induce me to examine the roots of these Vines, and I found the roots made the year before were entirely rotten, and that, too, as far back as where the soil had become soddened from the decay of the carrion, so that the Vines were almost deprived of roots. The soil was taken out, and the carrion taken away; fresh soil was added, and fresh Vines planted. These grew well, and nothing occurred afterwards to check the progress of the Vines. This fact is quite sufficient to convince me that carrion is a very objectionable substance to put into Vine borders.

Vines are gross feeders no doubt, but to make up for any deficiency in growth or produce, any stimulant given in a liquid form, even if it savours of carrion, is far more suitable than burying flesh; and if a border has proper soil and is well drained no harm, but, on the contrary, a great benefit will no doubt be derived from its use in that way at the proper time. The gardener who told "INQUIRER's" employer that Vine roots would go half a mile to get a taste of the carrion is perhaps able to refute what I have stated above; but I think he must have meant that they would go half a mile to escape it, if they go that distance at all. I think "INQUIRER" could not have given better advice.—THOMAS RECORD.

### PEARS CRACKING.

I HAVE planted a small outlying garden, which formerly was a garden to a cottage, with choice pyramid Apple and Pear trees. After three or four seasons' trial I find the Pears (not all the kinds) have a great tendency to crack, like the specimen I enclose, to the extent of about one-third of the crop. This happens very much with Bergamot Esperen and Beurré d'Isle. Can you suggest what might be the cause? The soil is a strong loam with, in some places, clay underneath, but the

district generally is celebrated for Apples, and my Apple trees in the same garden do very well.—A. G., *Beaminster, Dorset*.

[An experienced gardener tells us that he has observed that the fruit on the side of a tree most exposed to the cold winds is most liable to be cracked, the injury being done when the fruit is in a young state. We have also observed that cracking prevails in the more tender varieties, and where the soil and subsoil are cold. The last contingency seems to affect your trees; if so, cutting away the deep-striking roots, burning some of the clay and mixing it with the surface, keeping the surface also slightly manured and mulched, would be remedial.]

### THE NELUMBUM.

THE *Nelumbium* or Water Beans are not only remarkable for the beauty of their flowers, but they are credited with a list of virtues such as is possessed by few families of plants. These plants are of easy culture, and are readily increased by seeds. Propagation may also be effected by a division of the roots. In order to induce the plants to flower freely strong stove heat is needed. The plants require rich loamy soil, and during the growing season the tank in which they are grown must be kept filled with water. In the winter the plants may be kept comparatively dry to afford them a period of rest.

In reference to the various purposes to which these plants are applied, I cannot do better than quote from Dr. Hogg, who, in his "Vegetable Kingdom," states that "The most remarkable species is *Nelumbium speciosum*, the Egyptian Bean of Pythagoras, the Lotus and Tamara of the Hindoos, and the Lien-Hoa of the Chinese. By the ancients it was regarded as the emblem of fertility, and with it the Egyptians decorated the heads of their idols Isis and Osiris. It is held sacred by the Hindoos, and serves for the floating shell of Vishnu and the seat of Brahma. Sir W. Jones says, 'The Thibetans are said to embellish their temples and altars with it; and a native of Nepal made prostration before it on entering my study, where the fine plant and beautiful flowers lay for examination.' Dr. Wight states that the leaves and flower-stalks abound in spiral vessels, which they extract and form into those wicks which, on great and solemn occasions, are burnt in the lamps of the Hindoos, placed before the shrines of their gods. The Chinese extol it for its virtues, and rank it among those plants which are employed in the composition of the 'Liquor of Immortality.' They eat the seeds as we do Filberts, but they are more difficult of digestion; and are preserved in different ways with sugar. The root of the plant they also admit to their tables; great quantities being pickled with salt and vinegar, and reserved to eat with rice; and when reduced to powder it makes excellent soup with water and milk. It is from this root that Chinese Arrow-root is said to be obtained. The leaves are much used for wrapping-up fruits, fish, salt provisions, &c.; and when dry the Chinese mix them with their smoking tobacco to render it softer and milder. The Japanese, Thunberg states, regard the plant as pleasing to the gods, the images of their idols being often represented sitting on its large leaves. Some of the heathens have pictures thus drawn, which they make use of to animate the minds of the pious upon their death-beds, and to raise their affections heavenward! The petals smell like the flowers of Anise, and are slightly acrid, being used as the flowers of the Roses.

"The roots of *N. luteum* are farinaceous, and agreeable when boiled, resembling in flavour those of the Sweet Potato

(Batatas); the seeds are also eagerly sought after by children and the Indians of North America."—W. J.

### SOLDIERS' GARDENS.

FROM an official paper lately published under the authority of Lord Napier of Magdala it seems that the movement for providing soldiers quartered in India with garden plots continues to afford very satisfactory results. So well is the interest sustained that more than eleven hundred men sacrificed their leisure last year to this profitable amusement. Nor were they the only people to benefit by their employment. At certain seasons the commissariat authorities purchased from regimental gardens ample supplies of fresh vegetables for the troops when none were to be obtained in the native bazaars. Then married soldiers were able to eke out their rather skinny rations with plenty of "green meat," without having to pay exorbitant sums to native gardeners. Viewing these results, there appears little question that the establishment of a similar system among the troops in England would be beneficial. If military gardeners do so well in India, in spite of a scorching climate and poor soil, even greater things might be

expected of them at home. The chief obstacle lying in the way of this innovation seems to be the difficulty in finding sufficient cultivable ground for the purpose in the neighbourhood of military quarters. Unless the gardens are close to barracks, so much time is wasted in going to and fro that the soldiers grow disheartened and give up the work in disgust. To a certain extent this has been found the case in India, Lord Napier reporting in favour of "company" gardens compared with "regimental," owing to the former being as a rule close to barracks while the latter are generally some distance away. Nor must it be omitted from consideration that soldier-gardeners would be subject

Fig. 79.—NELUMBUM LUTEUM.

to much severer competition at home than in India where they very often have the field to themselves. Here their produce would have to stand comparison with vegetables cultivated by skilled professionals under the most favourable circumstances. Nevertheless in spite of these and other difficulties, we are disposed to believe that after a time the experiment would prove successful. Although soldiers might not be able to raise such crops as regularly trained gardeners, they would have a great advantage over the latter in cheapness of labour, their own leisure time being sufficient for all purposes. That such a system, if established on a sound footing, would greatly add to the contentment of many soldiers with their profession, can scarcely be questioned in face of the results already achieved in India.—(*Globe*.)

### THINNING FRUITS.

THIS year the crop of both Apples and Pears has been enormous, but the fruit in consequence has been smaller than usual, and in the south of Scotland it is not keeping well. I think that not nearly enough is said on the necessity of thinning fruit. When I speak of it I am told, "Oh! it is easy in your small garden;" but if it pays in a small it must pay better in a large garden, and there is no doubt the fruit is much better flavoured as well as larger, and also there is less chance of a scabby next year. I have thinned some trees with excellent consequences this year. Cooking Apples are much more useful when large, and even Pines, I am certain, would sell better if half the crop were removed early. Peaches and

Apriots are always thinned, and I do wish you would urge the necessity of thinning the common fruits, for it certainly pays.—A POOR LADY.

### FITTONIA ARGYRONEURA FOR COVERING SURFACES IN PLANT STOVES.

GENERALLY speaking there are of necessity unsightly surfaces in all houses devoted to the culture of plants in pots, and the pots themselves are an eyesore, and any arrangement which can cover up these unsightly objects and transform them into surfaces pleasing to the eye is desirable. There are few things more harsh and unsightly than a lot of pots standing on a stone bench, even when a layer of spar or gravel is placed over it; and so long as such a number of plants are required in a moveable form for so many different purposes, as is the case at the present time, plants in pots are a necessity. We have tried many ways of hiding such surfaces, and the most pleasing and effective that we have adopted is to put a margin of Portland cement about an inch deep round the outer edge of the stone shelves, and fill up to the level of this margin with clean-washed gravel about the size that will pass through a quarter-inch sieve. In this cuttings of the above-named beautiful *Fittonia* are inserted, about 6 or 8 inches apart, all over the surface, putting a row at the edge next the passage considerably thicker. This is done early in spring, and the cuttings soon root and cover up the whole space with the most luxuriant and beautiful silver-veined foliage, which soon hides pots of ordinary dimensions, and forms a charming undergrowth that sets off to the best advantage the plants that are placed on it. A few cuttings of *Panicum variegatum* are put in the front line, and this soon hangs down to the pathway. On larger surfaces where it does not hide larger pots, it is still a great improvement as a groundwork on dead and often dirty surfaces. Plenty of moisture with an occasional watering with guano water insures a most luxuriant growth of large leaves. When it is necessary to re-arrange the plants in pots, the *Fittonia* sheds like a fleece, and an opening can be made anywhere for a pot. As a groundwork underneath Pitcher-plants, which require so much moisture, it forms a beautiful arrangement, and it can be renewed yearly at very little trouble, and is the means of saving much labour in keeping dead surfaces in moist warm houses clean and tidy.—D. THOMSON (in *The Gardener*).

### A FEW WORDS ABOUT STRAWBERRIES.

I INTENDED to have written a line in answer to "AN OLD SUBSCRIBER" last week, but could not find time. As he has appealed, however, to my judgment among others, I write to say—First, Mr. Lovel was kind enough in the *Journal of Horticulture* to offer me some plants of *La Grosse Sucrée*; he has since more than fulfilled his promise by sending me plants of eight or ten varieties, all this year's runners. Second, I have no doubt whatever on seeing them that Mr. Lovel can accomplish under his system all that he says. I was in my stove when the plants came, and my gardener came to tell me he wished me at once to see the plants, as he never saw such fine plants of one season's growth in his life. I can quite corroborate what he said, as they were as full in the crown and as strong in the foliage (and especially stout in the footstalk of the leaf) as most plants you would find, under ordinary treatment, at the end of the second summer.

There is no royal road to gardening, nor is any one system the only one to follow to produce good results. Mr. Lovel's garden is on the chalk Wolds, but by high cultivation and constant manuring he has brought the land where he grows his Strawberries into splendid condition. Thus it must be from the specimen of soil attached to the roots of the plants which he sent me, which had, I believe, been lifted from his nursery beds. Again, the chalk Wolds, though thin in staple, are more retentive of moisture than is generally supposed. The crops of Turnips to be found in many parts of the Yorkshire Wolds, growing apparently out of brash or stony soil, is a sure proof that, though the upper stratum soil is thin, the staple is better than it appears.

Though the constant renewal of Strawberry beds may be necessary in some gardens and advisable in others, yet I am confident, from my own experience, that if more attention were paid to keeping the ground clean and free from runners, properly mulching with manure in winter and with chopped straw in summer, that Strawberry beds may be kept in good

bearing condition for seven or eight years or upwards; but then neither fork nor spade should be allowed, and the roots should be kept to the surface by feeding with top-dressing, which—and there, I fancy, I differed from Mr. Luckhurst—had better not be put on in autumn, when it only induces to leaf-growth, but in winter, after the crowns are ripened and when the plant is storing up food in its roots, for future fruiting. I do not believe that in any good garden soil properly drained the roots are inactive during winter, even when there is no growth of foliage. Any person with experience in bulbs will know that roots are formed in abundance before leaf-growth, and to a less degree I am convinced that when the leaf falls and the sap is said to descend, or, in other words, ceases to ascend, the roots of fruit trees are not inactive except in heavy, undrained, uncongenial soils, when they will often rot away. There must be a certain circulation of sap, even in deciduous trees, to keep the buds plump and the bark healthy; but this is a digression.

May I ask whether the Vine borders at Arkleton and Pot-holm are concreted? I have always maintained that Vine roots are often injured by being kept too dry, and that so long as the subsoil is good there is no necessity to concrete borders, &c. If Vine roots are properly fed with top-dressings and plenty of liquid manure, and have water enough in the winter, they will not push their roots out of their prepared beds. If cultivators are afraid of water to the roots, then, as the Vine is a thirsty fellow with large leaves and rapid growth, it will send its roots elsewhere out of the border to find its supply of drink. I thought by this time the question of earthen need not be raised again. I remember a man burying some dead pigs in his Vine border, and wondered the Vines retrograded, and I believe he wanted to bury some more had he not been persuaded that Vine roots did not like a mass of corruption.—O. P. P.

I AM not an authority at all upon Strawberries, but still I have had some experience, chiefly through the kindness of Mr. Gloede, who is in such matters the most experienced person I know, and certainly the best packer of Strawberries I ever met with. His plants sent from Les Sablons, about nine miles from Fontainebleau in France, arrived at Knahton as fresh as when taken up. I cannot say the same of my countrymen.

As "AN OLD SUBSCRIBER," page 359, has mentioned my name, and appealed to me with others for an opinion, I cannot do less than accede to his wishes. I must say, without doubting anyone's word, that I never succeeded in raising a pound of Strawberries from plants set out in September. It is next door to a miracle. Plants set out so late, unless they have previously made their crowns, could not do so late in the year. When Sir Harry came out I had from Bath twenty-five plants which Mr. Gloede, who was staying with me, at once pronounced to be Hooper's Seedling, a sort that has an unerring mark—namely, before ripening it turns to a dark colour of black or Prussian-blue colour. I sent some of the plants to Mr. Nicholson of Eaglescliffe, Yorkshire, and he also said it was Hooper's Seedling. He sent me the true Sir Harry, which is exactly like its portrait in Mr. Underhill's pamphlet. It did not succeed at all with me; but Hooper's Seedling, planted in the spring and deprived of its flowers and runners, cast next year from two hundred to three hundred berries per plant. It is an excellent cropper and good family Strawberry. I regret that I ever gave it up. The foliage and berry were in form like Keens' Seedling.

In the same year I tried *La Grosse Sucrée* and *Marquise de la Tour Maubourg*, alias *Héricart de Thury*, and others kindly given to me by Mr. Gloede; but neither were equal to another of his gifts—namely, *Rivers' Eliza*, which for form of plant (tufted), cropping, flavour, and general good attributes is one of the best Strawberries to have.

As regards British Queen, she hates chalk and loves a ferruginous soil, such as Sussex, its paradise. She loves rich clay that requires a pickaxe to break up the ground; but I believe she may be grown successfully in light rich soil abounding in potash, which is the grand constituent of Strawberries. For this purpose night soil and cow manure liquid and solid are best.

Instead of *Carolina Superba*, *British Queen*, and *La Chalm-naise*, none of which like chalk, grow Dr. Hogg, and also try Mr. Radclyffe. In my opinion Dr. Hogg for all lands is the best representative of the British Queen.

I conclude with a selection of a few good Strawberries. Duke of Edinburgh (Dr. Boden), a well-formed Strawberry and of

superior flavour; Sir Joseph Paxton, Frogmore Pine, Dr. Hogg or Mr. Radclyffe, or both; Rivers' Eliza, Coombs, and Wonderful. For white produce, a most beautiful Strawberry, Biston White Pine, of apricot flavour when well ripened and yellow. It is also called Barnes's Large White; but it, the Hautbois race, the Alpines (Galande Red is best), Frogmore Late Pine, and Underhill's The Lady require to be highly ripened in order to be good. Leaving out the Hautbois race, of which Rivers' Royal Hautbois is the best to have, but not richer than the Black Hautbois, the Frogmore Late Pine when highly ripened, which is rarely the case, is the finest flavour of all.—W. F. RADCLYFFE.

#### CHESTER: A VISIT TO THE NEWTON NURSERIES.

THE old-established nurseries of Messrs. James Dickson and Sons are situated near to the Chester Railway general passenger station, and are readily reached by a new route which the Messrs. Dicksons have made for the convenience of visitors. The nurseries may also be reached in a few minutes from the Northgate Street station.

The main entrance to the nurseries is by a broad walk or drive, and on both sides are planted choice specimens of the plain and variegated kinds of Hollies and other ornamental shrubs. Hollies in particular were noticeable for their symmetrical shape and robust health. Intermixed with the shrubs were a choice collection of Gladioli, for which this nursery is famous, just coming into bloom, the spikes being from 4 to 5 feet high.

Attention is next directed to the plant houses, which contain a large and choice collection of stove and greenhouse plants, very clean and healthy and of a portable size, including Orchids and an assortment of Palms. This is a very suitable class of plants for dinner-table and house decoration, for the hardier kinds are found to succeed better in close confinement than many other kinds of plants.

Special attention is paid to Vines in pots, the present stock consisting of about two thousand fruiting and planting canes; and it is worthy of remark that thrips, red spider, and mildew are unknown throughout the entire stock. The pot Vines here are not drawn up in bottom heat and are not grown too thickly together, which is very important to the future well-being of the Vines.

We next come to a grand lot of tree Ferns. *Dicksonia antarctica* is of large size, with stems varying in height from 8 feet to 8 feet; these have been recently imported, but are thoroughly established. These are fine objects for conservatory decoration. One house contained a choice collection of succulents in various sizes. In a cool house is a fine collection of *Lilium auratum* in great variety. How is it these grand flowers are not more generally grown? In cold pits were a good collection of soft and hard-wooded Heaths and Epacris, for which, judging from the quantities grown, there is a great demand. Hardy Ferns are also grown. In order to meet the demand for hardy herbaceous plants these plants are extensively grown here. Of border Phloxes there is a good assortment: these are always in a moveable state, being grown in pots and plunged in quarters. There is also a fine collection of Chinese Pæonies, which ought to be grown by everybody who possesses a garden.

Owing to these nurseries being on such a large scale it is impossible to go into details, and it must suffice to point out a few leading features.

The stock of Roses consists of about fifty thousand standards and half-standards, and about the same quantity are grown on the Manetti stock and on the cultivated Briar, also a great number are on their own roots. In the fruit-tree department there is a large stock of well-grown and well-trained trees, and there is no trace of American or any other blight. The trees are grown in forms to suit the different requirements, from the highly trained wall standard to the diagonal cordons for walls, &c., to the single and double horizontal cordons for edgings of borders and low walls. The stock of fruit trees in a saleable condition extends over ten acres of ground, and they are all worked on stocks grown in the nurseries. Upwards of a hundred thousand fruit trees are either budded or grafted annually.

Forest trees are extensively grown. Of Larches there are upwards of twenty-five millions! Others are in like proportion. All are frequently transplanted. When planted singly in exposed situations the Syamora is well adapted for growing in the bleak districts of Wales. It will grow in almost any

kind of poor gravelly soil. The Lime is extensively grown chiefly the red-twigged variety; these are raised from layers so that the stock may be relied upon as being true. This is very important in avenue planting, so that one tree does not outgrow that of its neighbour. My experience of this variety is that it will succeed in poor gravelly soil, and will carry its foliage well on in the autumn, which is not the case with the common variety (*Tilia europæa*). Many thousands are raised annually—a proof of its popularity.

*Cedrus deodara* and others of the genus are extensively grown from the seedling to the well-grown specimen. The present stock is about 10,000. Of *Aucuba japonica* there are something like 15,000. They are raised annually. They succeed well in smoky districts of the manufacturing towns. The soil of the Rhododendron quarter is a light sandy loam, and seems well adapted to their growth. Of *B. ponticum* there is a fine lot, for which there is a great demand for game-cover planting; and from the fact that they are not grown in peat they are enabled to thrive well when planted out in any ordinary light loamy soil or shale. There is also a good collection of hybrid kinds, something like six thousand plants being propagated annually. Hollies are a special feature, and consist of the best kinds in cultivation. Noticeable was a variety named *minoros*, of robust appearance, which is valuable for planting near the sea-side, as it stands the sea breeze so well on the Welsh coast. The stock of Hollies consists of many thousands, the Gold and Silver kinds being especially good; some were good standards 8 to 12 feet high, with from 4 to 5 feet clear stems, suitable for specimens in open quarters.

Of hardy Conifers, *Abies Douglasii* is of rapid growth and makes a fine ornamental tree. It is thoroughly hardy, and will grow freely in almost any kind of soil, and is worthy of more extended cultivation; it is one of the noblest and most beautiful of the Fir tribe. *Abies nigra* is also good. There is also a fine stock of *Piceas* (Silver Fir) *Nordmanniana*, *grandis*, and *nobilis*; these grow into fine trees. *Cupressus Lawsoniana erecta viridis* also demands notice, for it is one of the finest hardy evergreens in cultivation; for symmetry and beauty it has no rival. This variety possesses the peculiarity of being green to the very stem. *Cupressus stricta* is also very handsome and distinct, and forms beautiful pyramidal trees resembling the Irish Yew, which makes it valuable when grown as a single specimen on lawns. *Cupressus lutea* is a beautiful golden variety. *Thuja borealis* is certainly the best of its class, and is well adapted for growing as single specimens; it is thoroughly hardy. *Thuja gigantea* makes a noble tree; it is also perfectly hardy. *Wellingtonia gigantea* is extensively grown. Although hardy, it is always better to plant it where it can be sheltered from cold winds. There is also a fine stock of the Austrian Pine, which is one of the hardiest of the whole tribe, it is well adapted for planting in exposed situations, and grows freely in the poorest of soils. *Spiræa salicifolia* is extensively raised for game-cover planting and for hedges on the Welsh mountains where the Quick will not succeed. There is also a good collection of Ghent *Azaleas* suitable for either forcing or for early bloom in the greenhouse, or to be grown out of doors to bloom in their natural season; many of them are deliciously scented. Of Ivies there are sixty varieties. *Hedera conglomerata* and *H. dentata* are two beautiful new varieties worthy of notice. The Gold and Silver variegated kinds grown in pots and trained to trelliswork are very effective for conservatory decoration in winter. There is a good collection of Willows of the scarlet, purple, black, and yellow-barked kinds. These have a very pretty effect when planted in masses on the margins of lakes or rivers. There are also some fine specimens of the Kilmarnock and American Weeping kinds. These are grown as standards, and are well adapted for growing as single specimens on lawns.

These nurseries are upwards of 200 acres in extent, are in admirable order, and reflect much credit on the able foreman Mr. James Boyd. An immense export trade of fruit and ornamental trees is carried on by this firm.—G. R. ALLIS.

**RIPEN STRAWBERRIES IN OCTOBER.**—My gardener pulled to-day (October 18th) a small dish of Black Prince Strawberries grown in the open air under a wall facing south. They were well coloured and of very fair flavour, but not equal to the summer-grown berries. The same bed bore a good crop this year, gathered early in July. Had it not been for the heavy rainfall we had last week I should have had a considerable quantity. This is a very unusual occurrence in such a cold climate as

we have in the north, and certainly says much for the pure air we have in this suburb of "smoky Newcastle."—THOMAS ADAMSON, *Springfield House, South Gosforth, Newcastle-on-Tyne.*

### GRAPES AT THE EDINBURGH SHOW.

As an exhibitor of Grapes and frequently a judge I see no difficulty whatever about what constitutes a bunch and what does not; but there exists, nevertheless, a wide difference between a true bunch and such monstrosities as are met with, and which are not so uncommon as many would seem to surmise.

A true bunch of Grapes is produced directly and immediately from any single bud of a Vine, but it should have no extraneous—no additional growths, either in the shape of wood or leaves; because wherever these are permitted the bunch ceases to be the outcome of a pure fruit-bud, and, being a mixture of wood and fruit-buds, becomes a monstrosity.

You must not define what shape a bunch should be: hence to aver that a simple bud may not push forth a stem, split, and branching into duplicate stems, is an incongruity, provided always these duplicate stems have an immediate and indivisible base origin—that is, come together from the eye. By the weight and finish of the legitimate produce of such alone is real skill in culture shown.

Where, however, an accidental or adventitious bud pushes forth a mixture of wood and flowers, the latter in duplicate bunches close together, even if the wood growth is removed to influence the whole in forming one huge mass of Grapes, these cannot be called a bunch, but is the aggregate produce of a twin branchlet, fasciated or otherwise.

As this subject seems so indifferently understood I send a sketch (fig. 80) of a monstrous and improper bunch, which may occasionally, however, be considered a true one. A growing shoot was pinched off in its very infancy as marked at *a*. The berries, nevertheless, could have been so arranged as to cover this, and thus what are two bunches be made to appear as one!

Finally, in regard to the two bunches lately shown, I think some of the controversialists may overlook the fact that judges' decisions are final if no complaints were made within reasonable time after the decisions.

I do not believe the Judges acted unjustly even, and it becomes probable they erred in judgment or by oversight; but if any accident happened to either bunch during process of weighing it will conduce to better understanding and greater satisfaction if they communicate together and see whether some statement may not be tendered to lessen the irritation which exists.—WILLIAM EARLEY, *Valentines.*

Fig. 80.

I AM truly sorry that any unpleasantness has arisen about the large bunches of Grapes. There are several points I can clear up to show that I fully believe the Show from first to last was conducted in a perfectly honourable way. In the first place, I believe that no one was admitted except the Judges, Stewards of the Show, and members of the Committee; and to prove what I say, a friend of my own—a gardener and a member of the London Pomological Society—who travelled down with me in the train from London, came to take a hasty glance at the Show about 7 A.M., because he was obliged to start with the train soon after eight, he was bundled out as soon as it was found he was not in office.

Now comes the subject of weighing the Grapes. I saw them weighed, and nothing could be fairer than the way it was done, and I do not believe a person was present but those I have mentioned, but I will not be positive on this head, and certainly no Grapes could be more carefully handled and more tenderly dealt with. Then as regards the photographing: that was done to oblige the proprietors of the *Gardeners' Chronicle*, and they were carried near to the window for light. I certainly did not see the slip mentioned by Mr. Dickson. With regard to the clapping of hands, that was not done in any

party spirit. It was simply an outburst of enthusiasm when the noble cluster turned the scale at 26 lbs. I beg of Mr. Dickson not to think that we had any spite towards him. I for one have never seen, to my knowledge, either him or Mr. Curror, consequently could have no selfish interest in the affair.

Now comes the question, Was it one bunch or two? I was under the impression it was one, and am still; but of this I think the three gentlemen who acted as Judges, and the Judges for the Veitch Memorial Medal who followed them, can of course easily settle that point.—ONE OF THE FRUIT JUDGES, BUT NOT OF THE LARGE BUNCHES.

### NOTES AND GLEANINGS.

THE FUNDED STOCK of the Gardeners' Royal Benevolent Institution has been increased by the sum of £200, making the total amount now standing in the names of the trustees £10,600.

MESSRS. JAMES VEITCH & SONS have decided to hold another of their series of FRUIT SHOWS next year, and to repeat their former schedule. It will be held in the garden of the Royal Horticultural Society at South Kensington, simultaneously with the Society's Show on the 19th of July.

WE have had many inquiries about the FRENCH PRUNING SCISSORS recommended by Mr. Taylor a week or two ago, and we are now informed that they can be had of Mr. Fisher in Fleet Street. This useful and invaluable little tool is the *secateur* of the French, and may be carried in the pocket as conveniently as a pruning-knife, and the amount of work that can be performed with it is much greater and done with greater ease to the operator than by the ordinary pruning-knife. We annex an illustration, which will give our readers an idea of it. It is represented as being open in the cut.

Fig. 81.

WE are authorised by Messrs. Hooper of Covent Garden, to announce that all competitors for their POTATO PRIZES at the forthcoming Great Fruit Show of the Royal Horticultural Society on the 10th November, must deliver their Potatoes at South Kensington not later than Wednesday the 3rd, as the weighing will take place on the 4th.

MR. WILLIAM BULL has again offered his prizes of silver cups to be competed for at the GREAT SUMMER SHOW on the 7th and 8th June, and at the Provincial Show of the Royal Horticultural Society in 1876.

MESSRS. SUTTON & SONS of Reading have intimated their intention of offering a series of PRIZES FOR VEGETABLES in seven classes at the great show of the Royal Horticultural Society to be held in 1878. These prizes will be open to the competition of *bona fide* gentlemen's or noblemen's gardeners or gentlemen amateurs.

MR. JACKSON, gardener to Col. Smyth, Walton-le-Wold, Louth, has sent us flowering spikes of *Polygonum amplexicaule*, introduced by Col. E. Smyth from India four or five years ago. He finds it perfectly hardy. For out flowers he justly thinks it very suitable, especially for the vase. The plant this week had 130 spikes in flower, and has been full ever since July. No wet seems to injure its bloom. Dr. Hooker sent for a plant in exchange for Saxifrage last year.

THE death is announced of SIGISMUND RUCKER, Esq., and in him has passed away one of the most liberal patrons of gardening. He died, aged sixty-six, at his residence West Hill, Wandsworth, on the 19th inst. Every branch of floriculture he loved and pursued ardently, but Orchids were his special favourite. His collections—for he made more than one—were rich and admirably cultivated, so that he well deserved to have his memory made prominent in the name of one species—*Stanhopia Ruckeri*. He was at one time a member of the Council of the Royal Horticultural Society. We know the intimate friend of Mr. Rucker who wrote as follows in one of the morning papers:—"No expense was spared in keeping up his collections, and his tact and temper always secured him the aid of first-class head gardeners, but he was his own chief gardener. Those who have been privileged to accompany him on his evening inspection of his plants by lantern light are aware how thoroughly and intimately he knew them all. His gardens, always open to those who

studied or valued plants, have taught many most valuable lessons. His death makes a blank no living orchidist can fill. In private life the charms of his conversation, assisted by his wonderful memory and quickness of thought, his unvarying kindness of disposition, and quiet and unostentatious readiness to help with kind offices or charity, made him beloved alike by rich and poor.—G. F. W."

### STRAWBERRIES PRODUCING TWO CROPS ANNUALLY.

A FRIEND of mine had last year some Strawberry plants that had a very good crop in June, and fruited again abundantly in October and November. I saw them, and the fruit in the autumn was really very abundant on every plant. He gave me some runners, and they had a good crop in June, and have now fruit and bloom. I gathered some last week nicely ripe; but the weather is so unfavourable I cannot expect many now.

I thought if I prevented them fruiting in June, perhaps they would fruit a month earlier or so, and then the weather would ripen them. Would you be kind enough to say what you think in the *Journal*? Of course they are in the open air (no protection).—G. C., *Bramley Hill, Croydon*.

[You can obtain inch bones from any of the manure dealers.]

### A PLAGUE OF ANTS.

A LADY, who resides in South Kensington near the Horticultural Gardens, writes that "a perfect plague of small white ants have invaded the lower part of this house—kitchen, pantry, &c., and we are making fierce war upon them by stopping up all holes with putty and repainting the woodwork. I hope this may be effectual without more poisonous remedies. Are white ants natives of London, or have they emanated from the Indian Exhibition at the International?—C. M."

[I presume that the small white ants mentioned in the accompanying letter are not what are ordinarily known as white ants—that is, a species of the very destructive genus *Termes*, but the too common domestic ant, which appears now to have become domiciled in various parts of England, and especially in London. If my supposition be correct, there are two plans which may be advantageously adopted for their destruction. If the entrance to their nest in the brickwork of the walls of the house can be discovered, rags dipped in turpentine thrust into the mouth of the hole will kill them. If this cannot be discovered, bits of raw meat should be laid in their tracks; this will attract them by hundreds, and the meat should then be dipped suddenly in boiling water.—L. O. W.]

### NOTES ON VILLA AND SUBURBAN GARDENING.

#### KITCHEN GARDEN.

TAKE every favourable opportunity to finish earthing the late rows of Celery; through so much wet the soil of that which was previously done will have settled down so much as to need more earth. Our plants were at one time much affected by the maggot in the leaf, which threatened to destroy some of the plants. A regular course of hand-picking has pretty well cleared them off it, and during the past three weeks the plants have grown with great vigour, and more earth than usual is this year necessary. We have a row growing by the side of an Apple tree, the leaves of which have been affected seriously with a kind of spot which fell early upon the Celery and communicated the disease to the plants, which nearly killed most of them at that spot, but not elsewhere. This being an early crop it was dug-up before the Celery was quite useless.

In dry days also earth-up Coleworts and late-planted Kales, and plant-out Red Cabbage plants adjoining the winter or spring bed. If this cannot be done now defer it till the spring. There is this fact to be remembered—that autumn plants produce the largest heads, which is a consideration with some growers. Asparagus tops should now be cut off, and the beds cleaned and dressed—that is, by first putting a thin layer of rotten manure on the beds, and then covering that with a layer of earth taken from the alleys between them; then cut down the sides to their proper width, and leave them for the winter. In the spring much of this covering of earth must be raked off, but if possible the manure should be left to benefit the plants during summer.

Veitch's Autumn Cauliflower from late planting will now be coming in well; these must be cut before being injured by frost, as the flavour is much impaired by too low a temperature.

My plan is to pull or dig each plant up by the root, and take them to the root shed, and lay them in earth, where they keep well, and if the season is favourable Cauliflowers may be had up to the time when Broccoli is ready for use. All vacant ground should now be cleared, and manures be in readiness to wheel on at the first opportunity, ready for trenching-in when the leaves have mostly fallen.

#### FRUIT GARDEN.

With me many sorts of Apples are not keeping well, but Pears keep better and are larger than usual; therefore it will be necessary to frequently look over the stock and pick out those affected for immediate use. It is time to think about planting fresh trees of any sort that may be required. I advocate early planting—that is, plant as soon as the wood is properly ripened, so that after planting it will not shrivel through the operation. Some sorts of Pears do not ripen-off so early as Apples, and should be left longer in consequence of their making more fleshy wood; however, the stations for them may be prepared, so that the planting may be done more expeditiously. The places should be dug up at least 2 feet deep, and if there is a clayey subsoil sufficient of it should be removed in order to put in a little drainage and replace the clay, if possible, with better soil. It is not advisable to make the soil too rich at first, for, as a rule, young trees make a sufficiently vigorous growth without a stimulant for the first year or two. In most cases it is better to trench-in fresh soil or manure after the tree has arrived at the fruiting state.

Strawberry beds should now be cleaned, and have a winter-dressing of manure; but young plants put out this year will not need this treatment. Those in pots for forcing ought to be induced to ripen-off a little before laying them up for the winter, by placing them on a dry bottom, and taking care that they do not root through the pots, and keep all bad foliage and runners cut off.

#### FLOWER GARDEN.

Delay no longer the work of putting in cuttings of *Calceolarias*, as frost may set in and destroy the plants. It is, however, just the time for the work, so that the cuttings may be rooted before the end of the year. They will bear a little cold and damp, consequently they do well if rooted in a cold frame. The work is done in this way: The frame is first placed on the ground and two-thirds filled with any rough material, such as siftings of soil, then a little layer of garden soil broken-up fine, and on this a mixture of common soil and sand sifted fine. This should be made firm, and the frame should be filled up to within 6 or 8 inches of the glass. The cuttings should be inserted 2 inches apart, affixing each one firmly. After all are in, water well, and afterwards keep the frame nearly closed night and day. They must not flag from the sun, or the chances are they will die. Sprinkle them occasionally and protect from frost, and they are about the surest thing to strike root that I know of. *Gazania*, *Pansies*, *Alyssum variegatum*, and the scarlet *Melindres Verbena* root well, and also keep well during the winter in the same way.—THOMAS RECORD.

### MR. THOMAS APPLEBY.

THIS veteran gardener died on the 20th inst., in his 80th year, at his residence, Park Avenue, Longlight, Manchester.

When this *Journal* was first published we sought the aid of one specially skilled in floriculture, and we obtained that aid from Mr. Appleby. To our first number, and for many years subsequently, he contributed "The Week's Flower Gardening." In the first of those contributions he wrote this sentence—"We have tasted its pleasures for nearly half a century, and are desirous to increase in others the taste. If we can make the culture of flowers more general, and the practice more easy, our object will be accomplished, and we shall think our attempt will have been a mite cast into the treasury of human happiness." That he did succeed our correspondent columns bore testimony, and the desire for information which he promoted he had there to satisfy. He was then manager of the Pine Apple Nursery at St. John's Wood. Previously he had been gardener to T. Brooklehurst, Esq., near Macclesfield, Cheshire, in the care of whose collection of Orchids he improved his knowledge of their culture so as to enable him to furnish that excellent series of communications to our columns which we have published since in the volume entitled "The Orchid Manual."

Mr. Appleby only ceased from being on our staff when his business engagements and declining health rendered his withdrawal imperative.

### ODONTOGLOSSUM HASTATUM.

THE *Odontoglossums* are the princes of the cool Orchid house—that is, a large proportion of the genus succeeds in

almost a greenhouse temperature. The most beautiful amongst them are adapted for the coolest house, such as *O. crispum*, *O. Pescatorea*, *O. triumphans*. Another section do best in a house with a temperature about 5° or 10° higher during the winter months. These comprise *Odontoglossum hastilabium*, *O. citrosmum*, and the subject of which the engraving is a very good illustration, *O. hastatum*. Like nearly the whole of the genus it succeeds best in a pot with plenty of drainage,

Fig. 62.—*ODONTOGLOSSUM HASTATUM*.

and the ordinary potting material of sphagnum and fibry peat.

*O. hastatum* is a Mexican species, and, like most of the introductions from that country, it does not require quite so much water at the roots, especially in the winter or at the time that the pseudo-bulbs are resting preparatory to the plants making a new growth. The *Odontoglossums* are not very subject to the attacks of insect pests, but green fly infects the flower-spikes,

and does some mischief before the flowers open; the best way is to brush the insects off.

#### NEAR AND AMONG THE ANTIEDILUVIANS.

No. 2.

In the graveyard on the north side of Lyme Regis church stands a common round-topped headstone in memory of Joseph

Anning, with this brief appendix—"Also of his sister MARY ANNING, who died March the 9th, 1847, aged 47 years." No memorial could be less attractive, and it seems very incongruous when you look inside the church at the noble window, placed there, to do her honour, by the vicar and a few members of the Geological Society. Yet it is not incongruous; for the headstone is the modest record by the relatives, and the window is the record of the estimation in which she was held by the public. The window includes medallion pictures of every form of benevolence—visiting and relieving the sick, the poor, the bereaved, and the imprisoned.

Mary Anning was a thoroughly Christian woman. Like another Mary—Mary Somerville, she neglected none of the duties of private life; and the science she loved, each fossil she found, served only as "records of God before the deluge." She was the daughter of a carpenter, left an orphan when only eleven years old, and as a mode of breadwinning she walked to the seashore to seek for some of the strange forms she had seen others seeking for. She found one, and returning towards home with it in her hand a lady saw it, and gave her for it half a crown. That decided her to pursue the researches which brought to her independence and fame—a fame so wide-spread as to justify her telling the King of Saxony, "I am well known throughout the whole of Europe."

A few months after her first "find" she saw in the lias strata the bones of some animal projecting. Men hired by her dug it out. She sold the skeleton for £23, and it is now that Ichthyosaurus so well known in the geological gallery of the British Museum.

She corresponded with Home, Buckland, Conybeare, De la Beche, and Cuvier; and the shop she established for the sale of fossils was the repository whence they and other students derived illustrative specimens. It was not until 1820 that Cuvier completed the designation of the structure of the Ichthyosaurus, so that ten years had elapsed during the research for its members—the same number of years as were occupied in the siege of Troy; and one of her admirers observed, "Miss Anning figured throughout—was, in fact, a Helen to the geologists."

Admiring Miss Anning's character both as a woman and as an indomitable geologist I inquired for her portrait, and was astounded by the reply that here none existed. This seemed so incredible that I sought out her nearest surviving relatives. One of these proved to be Mrs. Jerrard, the wife of a butcher; and on being admitted to her parlour I rejoiced no little to see a small oil painting of Miss Anning hanging against the wall. There was no mistaking it; the simple straw cottage bonnet, the sober-coloured dress, the large geologists' hammer in her hand, the basket for specimens on her arm, the kindly yet self-reliant expression, all coincided with the remembrance rendered faint by a lapse of about forty years. I obtained permission to have it photographed, and perhaps copies may be obtained from the photographer, Mr. Walter, at Lyme Regis. From that photograph the wood engraving accompanying these notes was taken.

Some one may growl forth the query, What has geology to do with topics appropriate for these columns? I reply, Much. Geology discovered the coprolites particularised in the first of my notes: it is, in other words, the natural history of our globe. Everything growing upon it is connected with geology. Every stratum has particular constituents; and a knowledge of this and of the nature of those constituents enabled M. Berthollet to double the produce from a poor soil by bringing to the surface some of the under strata. The geologist who led

to a supply of gypsum (sulphate of lime), without which no Clover will flourish, and he who warned cultivators against the employment of a limestone because it contained magnesia, are only a few instances justifying the American professor's thesis—"Geology has strong claims to regard on the ground of positive utility." All soils are formed from the rocks and strata of our globe; and as the strata are all arranged in a certain order, and as those associated often differ materially in their composition, the strata immediately beneath a cultivated soil may, and often does, contain constituents capable of improving it; and a knowledge of the strata is also one of the best guides in effecting drainage economically.

I once heard some quotation from Shakespeare to show that he had a knowledge of geology; but still more recently have I known a controversy and many quotations to show that the poet must have been of the military profession. I expressed a belief that he had a store of general knowledge which enabled him to write correctly on any professional topic. The reply to me was, "Perhaps you can show reasons to believe he was a gardener?" That quotations from his plays can be gathered

quite as strong to sustain such an opinion as there can to sustain the belief that he was a soldier, the following may suffice.

He names in most of his plays many flowers familiarly and their arrangement in "the curious knotted garden"—(*Love's Labour Lost*, A. i., s. 1). Of fruits he knew the popular names—"I'm withered like an old Apple-John," a variety now known as the Winter Greening—(*1 Hen. IV.*, A. iii., s. 8). His knowledge of fruit-culture was sound, for he warns against injudicious grafting—"Our scions put in wild and savage stock, sprout up so suddenly into the clouds and overgrow the grafters."—(*Hen. V.*, A. iii., s. 5). Further knowledge of fruit culture is evinced in these other passages—

"You see we marry  
A gentle scion to the wildest stock;  
And make conceive a bark of baser  
kind  
By bud of nobler race. This is an  
art  
Which does mend nature, change  
it rather; but  
The art itself is nature."  
—(*Winter's Tale*, A. iv.).

"We at time of year  
Do wound the bark, the skin of our fruit trees,  
Least, being overpruned with sap and blood,  
With too much riches, it confound itself."  
—(*King Richard II.*, A. iii.).

"All superfluous branches  
We lop away that bearing boughs may live."  
—(*King Richard II.*, A. iii.).

"Go, bind thou up yon dangling Apricocks  
Which, like unruly children, make their dams  
Stoop with oppression of their prodigal weight;  
Give some supportance to the bending twigs."  
—(*King Richard II.*, A. iii.).

—G.

## AGAVE AMERICANA SEED-VESSELS AMONG THE OFFSETS.

### DRACENA INDIVISA SEEDS RIPENING.

AN American Aloe has this autumn flowered at St. Michael's Mount. Among the ordinary suckers thrown-up at such times are many like the enclosed, which seem to be a regular seed-vessel and flower. [It was a perfect seed-vessel.—EDS.] This seems strange, as if the tendency to flower should be extended from its normal position down to the very roots. Before this expansion these sports have the appearance of an unfolded Crocus.

*Dracena indivisa* ripened its seeds out of doors here last year on a plant about 15 feet in height, and I have hundreds of young plants from this seed. It has been a wonderful year

Fig. 83.—MARY ANNING.

for sub-tropical plants. My *Hedysium flavum* and *Ossia corymbosa* have been glorious. For four or five years neither of these plants have suffered from winter.—W. W. WINGFIELD, *Gulval, Cornwall.*

### THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 5.

In a collection of old proverbs, or, as some people term them, "musty saws," this occurs—"Fear keeps the garden better than the gardener." I acknowledge at first sight this appears enigmatical. Of course the allusion is not to keeping a garden in order, but to its protection in some way. My interpretation of it is as follows: Many of the plots of land enclosed as gardens two or three hundred years ago were partly used for the cultivation of various herbs prized on account of their real or supposed medicinal efficacy. Some of these were foreign, grown from seeds brought home by the Englishmen who were then beginning to form that acquaintance with distant lands which has so largely increased of late years. Hence a thief, who might otherwise have been tempted to trespass upon a gardener's domain to carry off plants which he could turn into money, would be, according to the superstition of those times, afraid to touch them, because he attributed to them powers of which he knew but little. That at least is my explanation of the proverb; if anyone can bring forth a better I shall be glad to hear from him.

They were singular folk, many of them, the gardeners of the Stuart period; and perhaps modern horticulturists are scarcely ready to accept the fact that an enthusiasm in the matter of plant-cultivation was once deemed a species of craze. I think this arose from the fact that some of the hermits—men who, either in or out of monastic orders, chose to lead sequestered lives—occupied themselves in this pursuit, making a living occasionally by vending the vegetables they grew. This is not out of the line of our present subject, as I shall show, because as one investigates the history of the suburbs of London, particularly with regard to the old garden grounds, one discovers here and there traces of these hermits—men not positively lunatics, I suppose, yet like Hamlet cranky in certain states of the wind, and who found occupation and solacement thus. The world generally was well content to leave them alone; and if, as it occasionally appears, they took possession of a plot to which they had no right, land was not then valuable near London.

In my preceding article I made reference to Clerkenwell and some of its old nurseries and gardens. Not very far from Clerkenwell Green, and in proximity to Smithfield, is the Charterhouse with its enclosed ground, which had, even at the date of the battle of Waterloo, an outlook towards the open country to the north. It is still a debatable question whether the piece of land originally called "No Man's Land," and afterwards in the occupation of the Carthusian monks, was or was not the plot purchased by Sir Walter Manning, in which many thousands of persons were buried during a visitation of the plague in the fourteenth century. To us it is of curious interest for this reason, that a writer on the history of Middlesex expatiates on the beauty of this spot and the flourishing condition of the trees and plants growing in the locality, which might be attributable to the enrichment of the soil by this multitude of dead. Besides the land belonging to the Charterhouse, and for centuries cultivated as a garden, there was an enclosed garden, a kind of nursery of the period, and called the "Brikes," mentioned in a deed of sale dated in the seventh year of Queen Elizabeth. The Wilderness, which, like some other places of the like name, was not a wilderness at all, but a piece of ground planted with some regularity by one or other of the noble residents there, said in a rare tract of 1707 to contain various scarce trees and shrubs, before it became a charitable institution, and was one of the early examples of an attempt at ornamental gardening. The appellation "Wilderness Row" still survives, but few trees to which we can assign a date of any antiquity. "One swallow does not make a summer" it is true, and one Pear tree does not represent an orchard necessarily; and yet I think "Pear Tree Street" not far distant tells the story of a long-surviving Pear tree which escaped the fate of its brethren in the orchards that formerly laid to the east of Clerkenwell. Possibly, as there is a "Cherry Tree Alley" in Bunhill Row near the Artillery Ground, the orchards extended in that direction also. But a little farther north there were marshy fields which it was hardly likely that anyone would plant with fruit trees, near

"Holy-well" and other springs, where Willow Walk and Willow Street tell a tale of the times when Finsbury was really "Fensbury," and only good for archery.—C.

### THE EFFECT OF DIFFERENT STOCKS ON GROS GUILLAUME GRAPE.

We have this Grape—so long misnamed Barbarossa—in two different houses grafted on the Muscat of Alexandria, and in another and cooler house on Black Hamburg roots. In the Muscat house, and in the cooler Hamburg house, we have it also on its own roots. The results under these three conditions are strikingly different. In both houses on the Muscat stock it swells its berries much more regularly and to a larger size than it does on its own roots in the same house and on Vines of the same age. In the cooler Black Hamburg house it neither makes such large berries nor bunches, but it colours much more rapidly than in Muscat temperature on the Muscat stocks, or than it colours on its own roots in either house. We have one vigorous Vine on its own roots, in which there are just two moderate-sized bunches; but these two bunches are not nearly so fine in berry as bunches four times their size on Muscat roots under heavy crops. We consider this one of the noblest-looking, and in every respect one of the best late Grapes in cultivation; and to those who wish to grow it to the greatest perfection in bunch and berry as well as high finish we would say, Graft it on a Muscat in a Muscat temperature, and allow the stock at the same time to develop either one or two bearing canes, as well as the graft of Gros Guillaume. It must be added that it fruits more freely under close pruning on the Muscat than on its own roots or on the Black Hamburg.—D. T.—(*The Gardener.*)

### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

#### HARDY FRUIT GARDEN.

MANY persons leave the fruit of late Pears on the trees until the middle of November, when frosts hold off, but fruit left upon the trees until so late in the season is not likely to ripen well. It will answer to leave fruits of all the kitchen sorts as long as possible, as the longer the fruit hangs firmly to the trees, and the leaves remain healthy, so will the fruit increase in size. We have had Uvedale's St. Germain hanging until the middle of November, and it will, perhaps, hang so late as that this year. All Pears intended for dessert purposes should be gathered by this time. Much that has been gathered shows signs of not keeping well, therefore it is the more necessary frequently to examine the fruit, and let all the decaying specimens be removed from the house at once. Damp and mould cause decay even if they do not apparently come in contact with sound fruit. The best way to store Pears is to lay the fruit down carefully one row deep, but in many instances it will be necessary to place another layer over the other. Apples, if intended for exhibition purposes, should be allowed to remain upon the trees as long as they are likely to increase in size, but they must be protected with nets to prevent birds from pecking them. The birds may just pick a small hole in the fruit, but from this small point decay will commence, and in a very short time the fruit is a mass of decay. As the fruit is gathered it must be carefully named.

All the fruit intended to keep late should be placed in a cool room, and the atmosphere ought not to be so dry as in the place where fruit is ripening. Apples keep well under the same circumstances as Pears. We have kept fine specimens for a special purpose in boxes of dry sand. Each fruit was wrapped up in paper, a layer of fruit was laid in the bottom of the box, and all the interstices filled in with white sand, a second layer of fruit was then laid over the other, sand was filled-in in the same way, the process being continued until the box was filled. Apples keep clean and free from taint in this way for a long period.

In wet weather nothing can be done in the way of planting, and it is a question whether any good can be done at trenching. Our own opinion is, that it is the most profitable way to discontinue working on the ground altogether when it is saturated with wet. It is a good opportunity to clear the weeds from walks and Box edgings, and all gravel walks may be rolled and made comfortable for the winter.

Those who contemplate making a plantation of Raspberry plants this season should make arrangements at once. The Raspberry delights in a deep, rich, unctuous soil, and will do better in a shady position than any other of our fruits. After the position for the bed or quarter has been determined the ground should be trenched about 2 feet deep, and plenty of rich manure should be incorporated with it during the operation. Any fine day after this the ground will be ready for planting. This to a certain extent may be done according to the taste of the owner.

The best way is to plant in rows 4 feet apart, and at the distance of 2 feet between the plants in the rows. A stout stick is driven into the ground at the end of each row, and about 4 feet 6 inches out of the ground; a stout wire is strained between the two sticks near the top, and another wire is strained 1 foot 3 inches lower; to these wires the Raspberry canes are trained about 6 or 9 inches apart. An easy way is to plant out 8 or 9½ feet apart; the canes, four or five from each stool, are tied together at the top, and two plants are made to meet together in the form of an arch. It is a rude way, and the most is not made of the ground. Its advantages are that no sticks are required, and the training is easily done. The planting should be done as soon as convenient. The best sort for general purposes is the Fastolf. Carter's Prolific and Fillbasket are also sorts with large fruit, and very free-bearing. A few plants of Yellow Antwerp should be planted, as they are useful as a dish for the dessert. The October Red, and Yellow may be planted for the same purpose, but they may only be looked at, as they seldom have any flavour.

#### FRUIT AND FORCING HOUSES.

**Vineries.**—We require to look very carefully over the bunches, as the berries are so apt to become mouldy, and if these are not removed at once decay quickly spreads. The leaves are now falling rapidly, and these must not be allowed to litter on the ground. All that are decayed we remove from the Vines by hand. On some of the Vines bunches of laterals have been formed beyond the bunches; these we can now cut away to one leaf from the bunch, which will further promote the circulation of air and light amongst the berries. If the day is fine, with sunshine, we throw open all the ventilators and have a good heat in the hot-water pipes, stopping it off again about one in the afternoon; by shutting-up time the pipes are cooled down and the ventilators are closed till morning. But suppose there is a change in the weather next day, a drizzling rain, a leaden sky, a thick fog, or what is as bad, a thick close moisture-laden atmosphere: well, we look inside the viney, the air is clear and dry, we do not open the ventilators in the morning, nor at noon if the sun does not come out, the pipes are kept quite cool, and ventilating the house would only let in damp. If the pipes were heated and air admitted more harm than good would arise from it.

We have taken advantage of the wet to have the early houses washed, the Vines washed and cleaned, and the borders renewed. The instructions for this are the same that have been recorded every season; still we would urge the necessity of thoroughly clearing off all the loose bark from the Vines without scraping it quite into the inner bark. Indeed we always think the Vines are injured when we see the old bark quite peeled off all over the house. It is not necessary to do this, but it is quite necessary to clear away all loose or superfluous bark about the old spurs. All these require to be very carefully cleaned. A little extra time now, when time is not so valuable to a gardener, will save days of anxiety, and oftentimes fruitless labour at a time when work is pressing on all hands. After sponging the canes well with strong soapy water, pressing it into all the crevices, then paint all over the young and old wood with the usual mixture. Those who require Grapes early in April will now be starting their Vines; let it be done very gradually at first, and without any artificial heat when the weather is fine.

#### MUSHROOM HOUSE.

The beds will now be in good bearing state, or showing signs of the coming crop by the surface of the bed becoming marked in places with a white substance, from which the tiny Mushroom forms itself, and then the numerous dots rapidly increase on those white patches. In other parts of the bed single specimens start up, or patches of three and four together. The largest Mushrooms are obtained when they come very thinly, the thick patches furnish quantities of "buttons." According to the state of the bed so will be the quality of the Mushrooms. If the bed is dry the crop will be tough and leathery; but the state of the bed must be seen to as soon as the Mushrooms appear. After the first gathering, water with tepid water, say 75° or 80°, and if the atmosphere of the house is naturally dry place some clean straw over the surface to retain moisture. Those who have to maintain a succession of Mushrooms through the winter months will have one bed ready to make up when the other comes into bearing. Even under the best management Mushroom beds are uncertain both in the quantity, produce, and length of time they continue in bearing. Sometimes the spawn is not so good one time as it is another, nor is it possible to have the beds to heat just as they are wanted. Notwithstanding all this, a good grower can generally tell at the time of spawning his bed how the crop will turn out—that is, presuming the spawn can be depended upon.

#### GREENHOUSE AND CONSERVATORY.

Chrysanthemums are now coming into flower, and we depend upon them for the next six weeks to supply us with nearly all the flowers required. We grow over 150 varieties, including some of all the different sections, and as they are trained and arranged in many different ways an excellent effect can

be produced. What the Chrysanthemum requires is to be potted in rich clayey loam, and to be well supplied with manure water from the time the buds set until the flowers open; if this is done the flowers are rich in colour, with stiff, enduring petals. Mildew is the worst enemy at this time, and most persistently attacks the leaves; as a preventive we dust all the leaves with flowers of sulphur as the plants are brought into the house; this will keep the enemy at bay for a long time, and should the disease spread further another application of sulphur will destroy it.

Tree Carnations have been taken in from out of doors, and are now showing abundance of flower from cuttings reared in March. The variety Miss Jolliffe put in at that time and grown on freely makes splendid plants for cutting flowers from. It is now to be seen in Covent Garden Market beautifully in flower. Very useful at present are the *Bouvardias Vreelandii* and *longiflora*; the plants have flowered all through the autumn months out of doors. Late plants taken into the greenhouse or conservatory will continue to produce flowers until Christmas. *Cyclamens* are throwing up hundreds of flowers. It is necessary to remove any decaying leaves or stalks from the plants at once; but it ought not to be necessary to remind all who have charge of hothouses at this season to keep all the plants clean and free from decaying leaves and flowers. We are tying and training specimen plants as opportunity offers.

#### FLOWER GARDEN.

It is no use trying to do anything here while walks and grass are surcharged with water. We swept up littery leaves where they were an eyesore, and as soon as it is possible to wheel barrows over the ground the flowers will be cleared off. The *Gladiolus* roots are being lifted, but we had to discontinue the work owing to the wet.—J. DOUGLAS.

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

JARREY.—Chrysanthemums November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

LOUGHBOUGH.—November 15th and 16th. Mr. W. Pallatt, 55, Baxtergate, Sec.

NORTHAMPTON (Chrysanthemums). November 16th and 17th. Mr. N. Gutteridge, 51, Denmark Road, Sec.

### TRADE CATALOGUES RECEIVED.

J. C. Wheeler & Sons.—Catalogue of Fruit Trees, Roses, Ornamental Shrubs, Flower Roots, &c.

G. Prince, 14, Market Street, Oxford.—Catalogue of Roses.

G. Cooling, 18, Broad Street, Bath.—Catalogue of Hyacinths and Roses.

A. M. C. Jongkindt-Coninck, Tottenham Nurseries, Dedemsvaart, near Zwolle, Netherlands.—Wholesale Trade List of Fruit Trees and Roses.

J. B. A. Deleuil, Marseilles.—Catalogue of *Amaryllis*, *Begonia*, &c.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

SEEDLING PEAR (*Burghley Gardens*).—The fruit received is very fine indeed, and a Pear of the first quality.

PEARS AND PLUMS ON EAST WALL (P.).—Any of those in your lists will ripen on an eastern aspect, but not on a northern.

GRAPES AT THE EDINBURGH SHOW (D. E. and others).—We cannot insert any further communications on this subject. The question "What is a bunch of Grapes?" is quite another subject.

EARLY PEARS—SALSAFY COOKING (H. S. F.).—Summer Doyenné, Citron des Carmes, Jargonelle, Williams' Bon Chrétien, Beurré d'Amans, and Summer Thoma. After you have scalded the Salsafy drain it, fry it lightly in white sauce, let it cool, then dip it in the white sauce and fry it again.

JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY (*Anonymous Inquirer*).—It is not now published. As to the back numbers, Messrs. Rankin & Co., Drury House, Drury Court, Strand, who were the publishers, can give you information.

SAVING FUCHSIA SEED (P. T. B.).—As the seeds are enveloped in a pulp, it is necessary, in order to preserve them, to cleanse them effectually. This is done by washing; bruise the berries with the hand, and mix them with water; as soon as the pulp is all washed off, pass the liquor through a hair-sieve fine enough to catch the seed, wash it repeatedly till it is quite clean, then dry it gradually; put it up in brown paper, and keep it in a dry room till spring. Sow it early in March in a mixture of light sandy loam and peat, cover slightly, and place the pots in a gentle hotbed. When the seedlings are half an inch high transplant them in rows across pots 5 inches wide—these will hold about twenty or thirty plants each, and then replace them in the hotbed. In these pots they may remain for a month or six weeks, and then they will require potting-off singly into 8-inch pots.

**FAMEUSE APPLE (G. B.).**—This the synonyme of De Nèige; the following is the description given in Dr. Hogg's "Fruit Manual":—"Fruit about the medium size, 2½ inches broad and 2 inches high; roundish, sometimes oblate. Skin tender, smooth, and shining, of a beautiful pale waxen yellow colour, tinged with pale red on the shaded side, but covered with deeper red on the side next the sun. Eye small, half open, and set in a shallow and plaited basin. Stalk half an inch long, inserted in a round and pretty deep cavity. Flesh pure white, very tender and delicate, sweet, and pleasantly flavoured. A very beautiful Apple, but not of great merit. It is for dessert use, and is in perfection from November to January. The tree is of a small habit of growth, hardy, and bears well; but in some soils it is liable to canker. This variety is supposed to be of Canadian origin, and was introduced to this country by a Mr. Barclay of Brompton, near London. It is grown very extensively in Canada, and is very highly appreciated."

**INTRODUCTION OF RHUBARB (J. F. N.).**—Gerard, in 1873, mentions that one species was then used as a pot herb like Spinach.

**GLADIOLUSES AND HOLLYHOCKS (A Young Gardener).**—To print the names of the numbers you name would require us to copy the whole in a florist's catalogue. Obtain one of these and select for yourself.

**HYDRICUS STYLACUS PROPAGATION (Amateur in Trouble).**—This is the *Althaea frutex*, which flowers in August or late summer, continuing up to frost. It is propagated by layers which may be made now, or cuttings of ripe shoots now under a handlight, not to be removed until the weather becomes warm. It is a very handsome plant, especially the double variety, and requires a rich light soil and a warm sunny situation.

**FRUIT TREES FOR A GARDEN (T. Taylor).**—Pyramid fruit trees answer well, but Peers and Apples, if you are in an open position, may be best as espaliers, being in that form more secure against winds. They may be trained upright to wires a foot apart, and 6 feet high or less, or horizontally, but the upright is certainly best for Peers. Pyramids or bushes, however, answer. *Peers*.—Doyenné d'Été, Jargonelle, Beurré de l'Assomption, Williams's Bon Chrétien, Souvenir du Congrès, Beurré Superfin, Louise Bonne de Jersey, Beurré Hardy, Marie Louise, Thompson's, Beurré Boes, General Todleben, Doyenné du Comice, Beurré Dial, Beurré Baschallier, Beurré d'Arenberg, Glou Morceau, Zéphirin Grégoire, and Bergamotte d'Espérance. *Steering Peers*.—Catillac and Verulam. *Apples*.—Desert—Mr. Gladstone, Red Astrachan, Summer Golden Pippin, Red Quarrenden, Mother Apple, Pine Golden Pippin, Margil, King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Golden Pippin, Beauré Nonpareil, Court of Wick, Duke of Devonshire, Melon Apple, Mannington Pearmain, Reineette du Canada, and Sturmer Pippin. *Kitchen Apples*.—Kewick Codlin, Lord Suffield, Cox's Pomona, Maux Codlin, Blenheim Orange, Gravenstein, Warner's King, Mère de Menage, Dumelow's Seedling, Bedfordshire Foundling, Northern Greening, and Gooseberry. *Dessert Pines*.—Early or July Gage, Golden Gage, De Montfort, Green Gage, Golden Espérance, Jefferson, Kibrie's, Transparent Gage, and Cox's Golden Drop. *Kitchen Pines*.—Early Rivers, Diamond, Prince Englebert, Victoria, Pond's Seedling, Yellow Magnum Bonum, Cluster Damsel, and White Damsel. *Cherries*.—Empress Eugénie, May Duke, Royal Duke, and Nouvelle Royale, with Kentish and Morello for culinary purposes. *Gooseberries*.—Yellow Champagne, Green Gage, Keen's Seedling, Red Warrington. *Large kinds*.—Red-Crown Bob, Prince Regent, Hopley's Companion. *White*.—Ostrich, Sheba's Queen, Wandering Girl. *Green*.—Angier, Conquering Hero, Thumper. *Yellow*.—Margold, Husbandman, and Broom Girl. *Currents*.—Black Naples, Lee's Prolific Black. *Red*.—La Hâive, Red Dutch, Victoria or Houghton Castle, and White Dutch.

**THE ROSES AGAINST A WOODEN RAILING (F. J.).**—Maréchal Niel would not do well, for the fence is too low. Such a position is little better than the open; but the harder kinds of Teas would do fairly.

**PRUNING CLEMATIS JACKMANI (Idem).**—There is no necessity to cut back 6 inches of the base annually; but having the shoots evenly disposed, cut back only to firm well-ripened wood, deferring the pruning until spring. Liliums of the harder kinds would succeed in a north border if the wall which causes the northern exposure be not over 10 feet high, and the Liliums not planted nearer to it than 4 feet.

**SOPHORA TETRAPTERA MICROPHYLLA (Amateur in Trouble).**—We do not know the species. It is probably *Edwardia grandiflora* or *E. microphylla*, both of which require to have a wall with a south or south-west aspect. Send us a spray of the shrub, and we may be able to identify it.

**LABURNUM INFESTED WITH INSECTS (G. R.).**—From your description of the insects we think they are a species of *Acarus* or red spider common to Laburnum and Elm trees in a dry soil and hot dry season. We should now dress the trunk and principal branches with paraffin oil, applying it with a brush, and reaching well the cracks and crevices of the bark, but keeping it from running down to the roots. Give also a mulching over the roots 2 or 3 inches thick of fresh soil or well-rotted manure, lightly stirring the surface soil. Early in July, or upon the appearance of the pest, syringe the trees thoroughly with a solution of soft soap, 3 ozs. to the gallon of water, and repeat in early August. If you were also to water freely in any dry weather in June or July onward it would tend to invigorate the trees and probably overcome the pest.

**STOVE FOR HEATING SMALL GREENHOUSE (A Reader).**—Only those stoves consuming oil, and only heating the air as it passes through the stove without heating the outer surfaces of the stove to a red heat, may with safety to plants be used without a flue or smoke pipe. The "vapourising stoves" are

of this kind, and one of those consuming a gallon of paraffin in six days, or 144 hours, at a cost of 3s., or 1d. per every four hours, will heat a space of 30 square feet. One kind is as good as another, and we cannot recommend dealers.

**TREES AND SHRUBS FOR SEASHORE PLANTING (Brian Boru).**—Evergreen Oak, *Pinus insignis*, *P. laevis*, with *Sycamore* and *Turkey Oak*, are what we advise of trees; and of shrubs *Tamarisk*, *Alaternus*, *Brooms*, double *Gorse*, *Euonymus*, *Escallonia macrantha*, *Hollies*, *Elders*, *Sea Buckthorn*, and *Guelder Rose* are most likely to succeed, but we do not consider they or only some of them would endure in a position where they will "get well splashed with sea spray." We should be obliged for information of sea-spray-enduring trees or shrubs.

**FRAGRANCES AND NEGOTIARIES FOR WEST WALL (East Worcestershire).**—Early Louise and Dr. Hogg Peaches, Balgovan and Lord Napier Nectarines.

**ROYAL HORTICULTURAL SOCIETY (D. de Foye).**—According to its eighth rule you would be eligible to compete for the Society's prizes with "specimens bona fide your property and in your possession one month previous to the show." There is not a word about the exhibitor being the grower of the specimens.

**STEPHANOTIS TURNING YELLOW (J. K. Durham).**—If you have not been applying any solution for killing insects in too strong doses we should imagine the change in the leaves is due to a low night temperature. With the increase of heat in the spring, and especially bottom heat, after repotting your plant will resume its usual vigour. The flowers of your *Lapageria* would in all probability have increased in size with the strength of the plant and generous culture. Try *L. rosea splendens*, and do not "part with it" hastily.

**NAMES OF FRUITS (R. O. Penge).**—Gansel's Bergamot. (*Mrs. Carlsale*).—Crataegus coccinea, Scarlet-fruited Thorn. (*Old Subscriber, Newlay*).—The Common Almond. (*Connaught Subscriber*).—2, Boston Russet, Hubbard's Pearmain; 4, Gager Pippin. Pear, No. 1, Suffolk Thorn; 2, Bergamotte Cadette. (*G. M. Swanton*).—You have not numbered or otherwise marked the fruit, and it is impossible to distinguish them. (*E. S.*).—1, Warner's King; 2, Peers's Pippin. (*Thomas Parker*).—1, General Todleben; 2, Adèle de St. Denis; 3, Calchasse; 4, Harrietie Bouvier; 5, Beurré d'Amanlis; 6, Dunmore; 7, Fondante de Charnon. (*Mrs. E. Pigeon*).—3, Beauty of Kent; 5, Blenheim Pippin; 10, Braddick's Nonpareil; 11, Sweeny Nonpareil; 23, Longville's Kernel; 25, Hambleton Deux Ans. (*M. E. P.*).—1, Lumboe's Seedling; 2, Golden Reineette; 3, Margil; 5, Delaware; 6, Boston Russet. Peers; 4, Beurré Rance; 5, and 6, Beurré de Capiaumont; 7, not known. (*G. Barfoot*).—1, Beurré Sir; 2, Beurré Drouleux; 3, Beurré Luizet; 4, not known; 5, Aston Town; 6, Cooke's Pippin. (*Rue in Urbe*).—1, Stamford Pippin; 3, Ganges; 4, Hoary Morning; 5, Golden Noble; 7, Winter Greening; 8, Duck's Bill. We cannot name more than six fruits. (*John T. Wood*).—Maiden's Blush. (*Smith & Simons*).—The Pear "Fair Maggie" is quite a local variety grown in Clydesdale, and has no other name. The specimens were quite rotten at the core. (*H. L.*).—1, Summer Portugal; 2, Winter Nells. (*Bertie*).—1, Belle de Noël; 2, Marie Louise; 3, Beurré Dial; 4, Louise Bonna of Jersey; 5, Soldat Espérance; 6, London Pippin. (*George Walpole*).—1, Nouveau Poiteau; 2, Bergamotte d'Espérance; 3, Emile d'Hayat; 4, Wormsley Pippin. (*F. Pm*).—1, Beurré Hardy; 2, Wormsley Orange. *Apples*: 1, Pismantoun Russet; 2, Winter Greening; 3, Royal Russet; 4, Golden Winter Pearmain. (*T. Clements*).—1, Due de Nemours; 2, Duchesse d'Angoulême; 3, Nouveau Poiteau; 4, Marie Louise d'Ucole; 5, Beurre Dial. (*W. F. L.*).—4, Calchasse Grosse; 5, Deux Sœurs; 6, Napoleon; 7, Passe Colmar; 8, Vicar of Winkfield; 9, not known.

**NAMES OF PLANTS (E. C. B.).**—The tree is the Hornbeam, *Carpinus betulus*. (*E. L. Ipswich*).—We cannot name florists' flowers.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### ALEXANDRA PALACE POULTRY SHOW.

THIS after many delays is among the Shows accomplished, and we were delighted with the Exhibition, the arrangements, and the management. Doubtless we could pick two or three holes, but the managers will have noticed them equally with ourselves, and for the first Show the success must be considered very great. We hope that when the reckoning time arrives there will be a goodly balance. It certainly was a fine spectacle to see the 2500 pens in one building, in one tier, with one glancing; but somehow it seemed poor after the Crystal Palace. Why we cannot say, but it continually gave us the idea of being something like a corn-exchange exhibition, and we think it must be because the central hall itself was so much smaller and more enclosed. We do not suppose this Exhibition will ever equal the Sydenham Show, but with due observance to one or two things we believe this may be made into an exhibition second only to it; but we should recommend in future its being held a week earlier in October, for the better accommodation of exhibitors wishing to send to older-established meetings.

**DORKINGS** had nine classes, cockerels and pullets of each variety being shown separately, with the exception of the Cuckoos, which were shown in pairs. Why this exception was made we do not know, as they are perhaps more difficult to match than any other variety. The Coloured class had twenty-nine entries. Here the Bath winner had an easy victory. If he keeps right he will shortly repay Mr. Hamilton for his large outlay; but we fancy we see already indications of swollen feet, otherwise he was in splendid condition. Second and third were nice birds. Pen 21 (fifth) a promising Rose-comb, very young, and we think when more advanced will supersede many that were placed above him on this occasion. Mr. Lingwood was highly commended with a bird of many good points, but he wanted the carriage of a Dorking. Pen 18 very crooked in the toe; in other respects we thought him equal to the winner. Pullets, twenty-nine entries. First (Mr. Parlett) by far the

largest bird in the class, with many other good points. The fourth (Walker) was a good bird, but not in such good condition as the second and third. Silver-Grey Dorkings were a small class but good (ten entries). First a nice bird, good in colour and legs; not quite so large as the second, but in other points superior, only entered at £4 4s. Second (Burnell) a fine bird, a little gouty in the toe; third Burnell, which we think at a future period will change positions with his brother. Pullets also a small class. First and second Burnell; the first, which also secured the cup, we think one of the best pullets we ever saw. The second was good in colour but smaller. Onokoos only six entries. The difficulty to which we have previously referred doubtless caused the class to be so small. The first was a good pen, well matched, of fair size, and beautiful in colour; second a nice pen, but we thought the cock small. Pen 77 (Burnell) we considered the second best cock, but he was mated with a small hen in many respects his inferior. White cockerels seven entries. First a nice bird, with rather a primrose tinge; second much better in colour; third pretty but small. Pullets.—Mrs. Haynes first and second with fair birds. The Selling class, £5 5s., first if straight in tail deserved his position; second good in some points but small; fourth rather queer in toe, which doubtless causes his appearance in this class. Pen 107 unnoticed we thought equal to some of the winners. The Dorking awards were very satisfactory.

**COCHINS.**—Buff Cochins were the best in numbers, but the quality was not up to the standard, as we had hoped. We liked Mrs. Aston Tindal's third-prize cock as well as the winner, for it was better in shape and symmetry, the first having an ugly comb. Mr. Frank's pen, 126, was very clear in colour but small. In pullets the winner was bad in colour and coarse in head. The second-prize pullet was a beauty, good in colour and shape. Messrs. Darby and Gee showed good birds but a little small; and pen 143, Mr. Frank's, deserved a better card, we thought. There were a great many very moderate birds in the class, but deficient in size. There were only six Partridge cockerels, but the quality was good. Pullets were a nice lot; the winner sound in back colour but too grizzled in thighs. Mr. Bennett's pen, 184, was a very good bird, and so was Mr. Derry's in 185. White cockerels were fair, but the winners only worthy of note. The second we liked the best. The third was poor in colour, otherwise very promising. 192 was the bird first at Aston Park; he is good in colour, but wants size. White pullets were a fine lot. The first-prize bird looked antique in head and legs, and so did Mr. Fowler's pen 211. The second-prize bird was bad in colour, while the third was a beauty. Mr. Woodgate's very highly commended bird, 207, did not show herself to advantage. In Blacks the winner was a long way ahead. He is perfect in all points—a little too large in tail, yet he is a beauty. Pullets were good, but we could not like the winner. She was red in neck-hackles and a dead black—not a particle of bloom about her. As we said last week, our choice was Mr. Frank's pen 219. We were disappointed with the Selling classes in Cochins. The winning Partridges in each class were much the best. We noticed some hens here in pens where pullets should only be; but then they were as thick as blackberries throughout the Show, and we really wonder so many escaped detection. We had an idea that birds would be found in these £5 5s. sale classes that would be run up at the auction; but there was hardly a bird in the classes worth more than the 10s shillings placed upon them in the catalogue.

**DARK BRAHMAS.**—Cockerels forty-one entries. Mr. Lingwood first, second, and third. We congratulate him, he is a thorough fancier, and all admit that he quite deserves his success. Of the third bird we quite agree with the selection of the Judge. The first was a fine chicken nicely marked, with pretty comb, good leg-feathering, and every promise to fill-out and make a grand bird. Second was a fine bird, but not equal to the first. The third had some superior points to either, but he always carried his wings on his shoulders, covering his hackles; this gave him a stunted appearance. As he gets more developed they may drop into their place. Fourth (Bennett), a good style of bird, but already very yellow; fifth a good colour but deficient in marking; sixth a fair bird, that if entered will have a good chance in the Mottled class at the Crystal Palace; seventh and eighth neat birds. 269 (Hon. Miss Pennant) as 260 (Hon. Mrs. Baillie Hamilton), are birds that will improve and probably be found in future prize lists. Dark Brahma pullets, seventy entries. Although the class was a large one and contained birds with some nice points, we could not find a really grand bird. The first (Percival), was beautifully marked, neat, and well-proportioned, but small and deficient in leg-feathering. The second and third (same owner), were much inferior to the first. The fourth was a good bird, well marked, and much larger and better-shaped than either of the first three. We should have decidedly placed her second. We liked many birds better than the second and third. Fifth (Miss Pennant) was a well-marked bird; sixth, seventh, and eighth were all well marked, and had points very superior. Pens 807 and 808 (Messrs. Newnham and Manby) are young and will improve. Pen 814 (Pritchard), nicely

marked. Pen 816 (same owner), unnoticed, we thought one of the best pens in the class. Mr. Evans and Mr. Peake also showed some good specimens. Cockerels (not to exceed £5 5s.), eighteen entries. First a pretty bird sound in colour and well feathered; second and third fair; fourth a short chicken. The fifth might compete well for the Baroness Burdett Coutts' prize at the Crystal Palace. Pair of pullets (not to exceed £5). 406 first, well matched, nicely pencilled, but deficient in leg-feathering; second not so good a pair with similar deficiency; third better feathered but not equal in markings.

**LIGHT BRAHMA.**—Cockerels thirty-one entries. The cup bird (Tedd) is fine, not in shape, but good in colour and comb, and well feathered. The second (Dean) neat and pretty in comb, but not so large as the first; third (Horsfall) a large bird; fourth (Dean) well shaped; six and seventh we preferred to fifth, they were better shaped and superior in style. 438 (Holmes) we thought deserved notice. Pullets, sixty-nine entries. Here we fancy we see a general improvement. 450 (Mrs. Bain), first neat in shape, large, and well feathered, but a trifle creamy. Second (Horsfall) not so large, but well shaped and very sound in colour. Third, fourth, and fifth nice birds, and deserved their position; sixth nice shaped but wanting in leg-feathering; seventh a nice bird; eighth (Potter) very good in colour. We should have liked to see her more forward in the prize list. Mr. Rice showed three good pens (highly commended), well grown and in splendid condition. Mr. Saville's two highly commended were pretty but small; Mr. Turner's and Mr. Holmes' birds well deserved notice. In the £5 5s. classes with the exception of the first-prize cockerel (Beldon), a stylish bird, we failed to find any pen worthy of special notice.

**SPANISH** disappointed us very much. The numbers, considering the season, were satisfactory, but the quality very inferior. The winners were forward birds, and the first had plenty of face, but the quality generally was coarse, and the combs ugly; second not so large in face; third, a neater bird, but we shall not expect to see either of them in the prize list of a large show again. Pens 581 and 582 (Chilcott) we should have placed before them; they have neat combs, not so much lob, but the quality was much superior. 565 deserved notice. Pullets sixteen entries, with three or four exceptions poor. The first (Goddard) was a nice bird, with a good open lob, but a twist in the neck, which is very prevalent with heavy-faced cocks, but not so often found in pullets, and which we consider very objectionable for breeding purposes. It was entered at £5, but bought in, we understand, at the auction at double that amount. The second and third were birds of good quality, but not so large in lob as the first. 600 (Chilcott) had the largest face, but she was not yet in trim for exhibition, and we think she will get very coarse.

**FRENCH.**—All the French classes were well filled, and appear to be rapidly making their way in public favour. Houdan cockerels numbered twenty-six entries. Mr. Dring was again in the front with a fine bird, nice in colour, but a little deficient in crest; second and third neat birds. 611, 620, 627, and 609, unnoticed, we marked as especially worthy attention. Pullets numbered thirty-three entries, and a lot of good birds were to be found here. First (Wood), was a fine bird in all points and deserved her position; second not so large; third (Copplestone), a grand bird. We think we should have placed her second. Mr. Dring and Mr. Hibbert showed some birds, highly commended. Nineteen birds in this class were distinguished by the Judge. The Crêves were good classes, but not so numerous as the Houdans. First (Knight) was a well-proportioned neat bird, with good crest and comb, and must have run the pullets very close for the cup; second (same owner), a fine bird, but not so neat as first; third (Malden), a good bird. The pullets numbered twenty-three entries, and some magnificent specimens were to be found. We walked down this class before the prize cards were placed on their pen, and on reaching pen 691 we thought we had found the winner, but in a second we caught sight of her next-door neighbour, pen 692. This quite dispelled the illusion. We thought her one of the best Crêve pullets we had ever seen; perfect in shape, of good size, crest, and comb. The cockerel was a good one, but we think she quite deserved the cup. The second was a large bird; the third very neat, and closely, we think, pressed by one or two highly commended pens.

**HAMBURGERS.**—This variety came well to the front, and all the good yards sent fine specimens. The winner in Golden-spangled cocks deserved his cup. He is a fine bird, and a model in points. After him we had a great liking for pen 705, and 709 (Blakeman) was a beautiful chicken. One or two of the best-marked birds wanted more style. Pullets were beautiful; the winners well chosen. Perhaps the first-prize bird had a little faded appearance, but her spangles made up for it. Silver-spangled cockerels were a pretty lot. Mr. Long's pen, 729, was good in wings and breast, but his legs were too white. 732 (Hallam) a good chicken with nice carriage. In pullets we thought Mr. Patrik's or the Duke of Sutherland's birds richer in colour, but not so perfect in markings as the winners. Golden-pencilled cockerels were a large and good class. The winner was a smart bird and well

shown; second also very good; for third place we preferred 751 (Beldon) or 759 (Tiekner). Pullets were a nice class, and must have been difficult to judge, so many were nearly equal in points. We liked the markings of Mr. Judson's bird (772) as well as any, but she was too pale in body colour. We liked the winner much, but thought the second and third might have changed places. Silver-pencils, as usual, made the smallest classes, but the quality made up for the deficient quantity. The Trantham cockerels were very smart birds, having remarkably good sickles. The pullets also were a nice lot, the pencillings of all the winners being extremely even and good. Blacks were truly beautiful. The winning Black cockerel was one of the best, if not the best Hamburg cockerel in the Show; his colour, shape, and head were beautiful. The other cockerels noticed were all good. Of those out of the prize list perhaps 799 (Preston) was our favourite. The pullets were a good lot, the winner very good all round; second also a nice pullet with true Hamburg shape. 811 (Hoyle), a nice bird with a good lobe. We think we saw some old hens here, and advise that they be kept at home in future, and not substituted for their daughters.

The GAME made extremely good classes. There were a large number undubbed, and of those many very good chickens. The winning Black Red cockerel was a beauty, good in all points, and carrying himself well; his tail is admirable, and head very fine. The other winners were good and deserved their places. We liked Mr. Bamford's pen, 823, very much, and thought it deserved a higher card. Black Red pullets were very grand. The winner who carried off the cup was a model in points and of very beautiful colour; second went to a peculiarly compact bird, and third was again after the style of the winner. Mr. Matthew's pen, 846, was a good pullet, capital in head and carriage. Brown Reds also made a splendid collection of birds. The winners in cockerels wanted more time, but of great promise. The fourth-prize bird was not dubbed. The Judge only awarded the prizes in this class, giving no other cards; but we fancied Mr. Palmer's or Mr. Cook's cockerels deserved a notice. The Brown Red pullets were a smart lot, and the winners well selected. We think we liked the third-prize pullet quite as well as the second, as there was something about the colour of the latter we did not quite fancy. Mr. Martin's pullet, 880, was a good bird, and with a nice head. In cockerels of any other variety first and second went to Duckwings, and the third to Piles. We much admired the second bird, and thought he was superior to the winner, being better in head, shape, and tail. The third Pile was a good bird, and came in a good third. 898 (Dutton) a very good Duckwing, as was 900 (Martin). In the Variety Game pullets we thought the winner beautiful; we could not detect a fault. There were one or two more good Duckwings in the class, and a nice Pile which won second, but everything was left behind by the first-prize bird.

MALAYS did not make large classes; and good chickens seem to be scarce, for the entries were poor, as they were at Oxford. The winning cockerel was a large bird with a regular Malay head and of fine shape, but he wants more time. He won the Malay cup. Second was a fine bird, but also wants more time; he promises to be a large bird, and is of good colour. The third bird was not enough of a Malay in shape, and we liked better Mr. Ridley's, or Mr. Hinton's quite as well. The winning pullets were all good, the second and first especially being very equal. We liked their colour, and their feathering looked hard and glossy. We noticed two or three cream-coloured birds in these classes. We say cream colour, because they were neither White nor Piles. We have seen about a good pen or two of Whites, and thought a class for them may draw some pairs out. They seem to be plentiful in Jersey.

POLANDS.—All three varieties were well represented. It was as nice a show of Poland chickens as we have seen for a long time. The winners in Golds were good; the third pullet a beauty, and if she was not too round-backed to be in the prize list at all we think she should have been first. The pair which received that honour were splendid chickens. In Silvers the second cockerel was a beauty; his wings quite perfect, and it must have been close between him and the first-prize pair for the latter honour. All Mr. Adkins's pullets had such good crests, being large and good in colour. Blacks were very fine, and here came the Poland cup. We can imagine great rejoicings at Little Ness on hearing that the cup had been wrested from the Golden and Silver for our old friends the Blacks. We doubt if the pullet would be much better, but we thought the second-prize cockerel was better than the cup bird, but the latter will in time be equal to him perhaps, as he is now full of pen feathers. Mr. Norwood's cockerels were very grand in crest and shape, and we thought 978 should have crept into the prize list; but the pullet with him, though enormous in crest, was not nicely shaped in her headgear, as she wanted her chignon putting on straight. Mr. Unsworth also showed a nice pair of chickens in this class; in fact, the whole collection was superior.

SILKIES were much admired. The winners were very white and perfect in point. The first-prize pair was sold at the

auction for £10 10s. It is surprising to find what large prices this variety fetches. Mr. Darby's pen was good, but there was a tendency to hooks, while Mr. Cresswell's, though splendid in fluff and shape, also seemed too heavily feathered in hooks and legs.

LEGHORNS made two very pretty classes, and the Brown variety had justice done to them, for the winning pullet was charming in head and shape. The Whites have much improved in ear, and here showed-up well, Mr. Fowler's cockerel being very smart and neat in carriage. Mr. Ward's, the third, were fine chickens and well shown.

VARIETY CLASS.—This was as pretty a medley as we have seen. The first-prize pair were Cuckoo Cochins; nice birds, but quite chickens as yet. Second went to White Poles. It is long since we saw them, and we hope they may be the fore-runners of other obsolete Polish breeds again coming. Third went to Black Minorcas, a nice pair; and not to Sultans, as we stated last week. And fourth to a pretty pair of Sultans, good in head and legs. 1012 (Croote) a fair pair of young White Minorcas.

BANTAMS.—Black Red Game cockerels, twenty-three pens. First (Ardagh), a nice racy-looking bird of good Game style; second a neat bird, in some points superior to first; third and fourth good birds. Mr. Maple, Mr. Shumach, Mr. Hall, and Dr. Adams, and one or two others showed birds that we think deserved some notice from the Judge. Pullets were a large class—forty-one entries, and a difficult task the Judge must have had. First was a graceful nice-looking pullet; second smaller, very neat and of good style; third, fourth, and fifth were good. Brown Red cockerels, eight entries, and pullets ten. Both classes were good, especially the latter. We strongly object to judges throwing commendations broadcast, as they soon lose their value, but we think Mr. Smith might be a little more bountiful. Any other variety cockerel.—Brownlie first and second with two pretty birds much similar in style to the bird Mr. Brownlie was so frequently successful with last year; third, a beautiful-coloured Duckwing undubbed. The pullet class numbered twenty-two entries. First and third, good Piles; second, a Duckwing, good in colour, but very large and rather thick. Black Bantams, fourteen entries. First (Shackleton), a nice pair, very neat in comb. Sebrights.—First, Silvers, the best coloured pen we have seen Mr. Leno show for a long period. Second (same owner), Golden; and third, Silver (Robertson). Any other variety was deficient in novelty and quality, the prizes going to White Rose-combs and White-booted. The first were fair birds.

DUCKS.—These were good classes. The first-prize pair, Aylesburys, exceedingly good in bill and shape; the second were, too, a fine pair, closely pressed, however, we thought by Mr. Fowler's fourth-prize pen. We liked 1362 (Walker), or 1359 (Sotham), as well as the third-prize pen. Rouens made a grand class, and Mr. Evans won another cup deservedly; second also very good and well shown; the third a beautiful pair of Ducks, the drake especially in fine feather. The class was capital throughout. Blacks were another superior class; pen after pen was a beauty, but the Duck was not good enough for him. Mr. Kellaway's pens were rather smaller than Mr. Sainsbury's, but we thought the latter gentleman's birds showed more condition and bloom. The ornamental class was lovely. The whole class could have been highly commended. It must have been a toss-up almost whether Carolinas, Mandarins, or Whistlers won the prizes.

GEES had only one class. We think two classes would pay at these shows, for there are so many ornamental breeds about which their owners would be glad to exhibit at these great meetings. The first prize were a grand pair of Embdens, as fine a pair as we ever remember to have seen shown by Mr. Fowler, and that is saying a good deal; second were very fine and heavy Toulouse. Mr. Nicholls sent a fine pen, and so did Mr. Fitz-Herbert.

TURKEYS had two classes, and the quality was really wonderful throughout. Mr. Walker came well to the front, winning with very fine birds. Mr. Gunnell, however, came very near him, and also exhibited some really fine specimens. We were much pleased with these classes, and think single birds in Turkeys will make a good speculation for other shows.

SELLING CLASSES were all very large. We may say we were mostly struck by Mr. Clark's second-prize Dorking cockerel, the first-prize pair of Light Brahmas of Mr. Petter's, and a fair pair of White Cochins of Mr. Carr's. The Duck Selling class was good, and the winners would do well in many an ordinary show. Mr. Tegetmeier's extra "Apterygine" drake was most peculiar, not having a sign of a wing on either side of his body.

#### PIGIONS.

TUMBLERS.—The Almonds were very good. The winner in cocks was a very tiny bird of pretty colour, but we almost preferred the second, he being better in head points. In hens the winner also deservedly took the cup, she was a beauty all round. 1875 birds were good, but we liked Mr. Reginald Bryce's birds better than the second-prize bird. Balbs or Beards were very

good, a very lovely Blue Bald winning the cup. A Blue Beard was second, and another nice Red Bald third. It was a splendid class, and difficult to judge we should think. In the rest of the Tumblers a splendid Black Mottled of Mr. Fulton's and a Yellow Agate of Mr. Yardley's call for especial remark.

BABES made a fine collection in quality, though the classes were not large. Mr. Fulton was well to the front with fine specimens; his Red cock was a beauty and was well first. The 1875 classes were fine. Mr. Firth showed a good Yellow, and Mr. P. H. Jones sent a Red which was but little inferior to it.

JACOBS in quality were wonderful, and we are sure it would be a class where the Judge would not pretend to please, for a more even lot it is impossible almost to see. Mr. Fulton's Black was a perfect gem, and the third White was a good bird. A good Red in nice bloom won the cup, closely pressed, however, by Mr. Fulton's second-prize bird.

FANTAILS had one class, in which all the birds were really good, and nearly every bird White. The winners were well chosen and very good in tails. We admired Mr. Serjeantson's v.h.c. bird extremely; and pen 2147 (Loversidge) was a capital White.

OWLS, OWLS, AND TURBITS.—In the former a good Black won first and another good one third, second going to a fair Yellow. Owls were very beautiful, and many of the specimens most minute in size and very elegant in head and shape. All the colours were represented; perhaps of them the Silvers were the best. Turbits were very charming. We saw pen after pen of really good birds. The cup Blue was a lovely bird and in fine condition. The first Yellow in the other class was good, and in fact all the noticed birds had much quality; and some of the unnoticed birds too, for why Mr. O. E. Crosswell's Black was left out in the cold we cannot imagine. He was to our mind as good a Black as there was in the Show.

OTHER CLASSES.—Trumpeters were small and select, the winners all being fine Blacks. Magpies were very good, the Blacks especially good, though the winning Yellow and Red in the other class were fine birds. Archangels were better than usual, and there was more colour than we generally find. Runts were a fair lot, with nothing much worthy of note. Antwerps made a very large party, and very good many of them were. The first Silver Dun Short-faced cock was a nice bird and well in first. The classes were good and the winners well chosen. In the Homing class a strong and useful pair of Blues were first, Blue Chequers taking second and third places. The Variety class was a pretty collection of fourteen pens; Frillbacks won first, Whole-coloured Ioe second, and Red Turbites third.

The Pigeon Sale classes were large, and there were some good birds cheap. In the special flying class for Homing birds Mr. Tegetmeier brought a splendid collection, and deservedly did well with them. The whole class was good, and more prizes could well have been given.

We hear Mr. Billett had the birds speedily packed at the close of the Show. Everyone we have spoken to on the subject tells us they had their birds back in good condition. We understand in the judging Mr. Hewitt took Dorkings, Cochins, French, and Waterfowl; Mr. Teebay, the Brahmas and Spanish; Mr. Smith, Game and Game Bantams; and Mr. Dixon the remainder, some of the Selling classes going to each of the Judges. In Pigeons Mr. Ridpath took the Fans and Jacobins; Mr. Charlton the Dragons, Owls, Short-faced Tumblers, and ditto Antwerps; and the Pouters with Mr. Esquilant, who also judged the other classes. The birds while at the Show were fed by Messrs. Spratt & Co.

#### WHICH BREED OF POULTRY EATS MOST?

	Cost.	Value of Eggs.	Value of Meat.	Total value.	Profit.
Brahmas ..	\$9.22	\$12.10	\$14.00	\$26.10	\$16.88
Cochins ..	10.15	11.82	14.60	26.42	16.27
Dorking ..	7.72	10.48	11.85	22.33	14.61
Houdans ..	5.35	15.26	9.15	24.41	19.06
Leghorn ..	7.03	16.10	7.30	23.40	16.37

Showing Houdans first, Brahmas second, Dorking last, while Cochins and Leghorns are nearly equal and vary little from Brahmas. The birds all coming so near would tend to confirm an opinion I have heard expressed, that all the pure breeds are equal enough in profit to allow one to consult fancy only in a choice of varieties, even with limited room.—(*American Pet Stock Bulletin*.)

#### BIRMINGHAM POULTRY SHOW.

THE poultry and Pigeon department promises to be unusually attractive, no fewer than sixty-five silver cups, varying in value from £20 down to £3, being offered; and the successful competitors will have the option of taking cash in every instance. The principal changes made in the schedule relate to the Pigeon classes, the entries of which in all cases will be for single birds instead of for pairs as formerly; whilst, as an experiment, persons are allowed to exhibit Pigeons on payment of an en-

trance fee of 5s. per pen, without becoming subscribers of £1 per annum. This will be a great boon to small fanciers, and should lead to a large increase in the number of entries.

We are requested to state that all letters and communications connected with the Show should be addressed to Mr. J. B. Lythall, Bingley Hall.—(*Midland Counties Herald*.)

#### EDENBRIDGE SHOW OF POULTRY, &c.

A more miserable day than last Wednesday week it is impossible to imagine. From the time we left the Alexandra Palace in the morning till we left Edenbridge at night the rain never ceased; it came down in one incessant downpour, and drowned everything. Mud was ankle deep everywhere. Baby rivulets ran along the roadsides, and made courses for themselves over the pathways. To get from the entrance gate to the poultry tent stepping stones had to be used to avoid the perfect sea of mud; and when once inside the emptiness of the building was positively painful. There were not half a dozen people in the place, and they looked at one another as if they were ashamed of being seen out in such weather. We can only hope the next day was a better one, or we fear the balance of the Society must be but small. We were really very sorry, for the schedule was a good one, the arrangements admirable, and the quality of the birds certainly above the average. Messrs. Hewitt and Teebay awarded the poultry prizes, and we thought in nearly every case the best birds won. Mr. Billett adjudicated on the Pigeons and Rabbits with satisfaction. It was a pity the Alexandra Palace Show clashed with it, as doubtless the entries were thus considerably lessened.

Coloured Dorkings came first on the list. The old birds were fair. Mr. Darby's pen was empty. Chickens were very good, the cup cockerel a great beauty and in fine condition. All the other noticed birds were good; in fact, it was a good class of Coloured chickens. Silver-Grays were not nearly so good, and we were disappointed with them. Here Mrs. Lee's pen was empty. Whites were much better, the winning chickens being really good, especially the pullet, the cockerel requiring more time to develop, but of great promise. Brahmas were a grand lot. The first-prize pair of old birds also took the £10 10s. champion cup for best pen in the Show. The second and third were grand pens; the second hen as good as the cup bird, but her mate wanted more time. Chickens were splendid, the winning pair beautiful, and second also a good pair; in fact, all the noticed pens were good. Old Lights were fair, the prize birds only deserving mention. The first chickens were capital, the cockerel very good all round, but his pullet a shade too pale in hackles. The second were also a nice pair of chickens. Cochins made small but good classes. The old Buff birds were rather out of feather. We liked the second-prize hen best of the old hens, but her companion was rapidly losing his hackles. The first were a good pen and in better feather. Buff chickens were capital, the winners especially good, as the pullet was good in colour and well feathered. In Blacks there was not anything worthy of notice except the two first-prize pairs and the cock in the third-prize pen. The winning cockerel was a smart bird and stood up well. Whites were very good, the old birds especially so. The first-prize cock is a good one, and the hen worthy of him; second and third also good, the cocks being very good in colour but wanting more time. Chickens were all very heavily feathered, and mostly raw-looking, but promising to make up well.

Hamburgs were a good lot, and we thought the birds very carefully judged. A very smart pair of Pencilled chickens won the cup, closely pressed, however, we should say, by one or two of the Spangled pens. The Spangled hens were particularly nice, and the Pencilled chickens made a class far above the southern average. Game were a smart lot. A fine pen of Piles took the cup, closely pressed we should say by Mr. Cock's Brown Reds. The first Black Red cockerel was a smart bird; the third-prize pen of Brown Red chickens were not half a bad pair, but the cockerel carried his tail too high, still they were cheap at 50s., the catalogue price. Spanish were only a moderate lot, but the chickens made the best muter, the winning pairs being fair specimens. Polish were a great improvement on last year. Good Silvers and White-crested Blacks won in old birds. In chickens the second-prize pair were a smart pair of the latter colour, well shown. French were very good. We are told that these classes never have half justice done to them at the hands of reporters; we deny the charge in toto, and say they have their dues as much as any other breeds. The old Houdans were five pens in number, the first-prize pair very large birds and good in points; but for second place we should have chosen the third-prize pen. Houdan chickens were good, but here the first-prize pair were deficient in claws, and we should have chosen out two or three better pens, though in carriage and symmetry the winning pen was good. We noticed here a great many bad combs upon otherwise perfect specimens. In old Orèves the winners were good. The hen in the first-prize pen very large and good; second and third also good, the latter hen superior to the second,

we thought. In chickens the first-prize pair were very good and capitally shown; second and third also good pairs; pullets again bring better than the cockerels. The Variety class was an afterthought, for it is numbered 84, and did not appear in the first schedules issued. Very smart Black Hamburgs won first and second, and good Brown Leghorns third. Game Bantams were good, and the winners well selected, the first-prize Pile chickens being really first-rate. In the other Bantam classes the Blacks were the best, though there was a nice pen of Laced among them, and Mr. Boissier's White-booted were good.

Ducks were splendid, Aylesburys and Rouens both being well represented. The Variety Duck class was an extremely pretty one. We noticed a very fine pen of Muscovies of Capt. Talbot, as good as we have seen for a long time, but what can they do against the ornamental breeds? Geese and Turkeys were good, the first-prize Black Norfolks of Lady Camden being very large, and the same pair we believe which won first at Tunbridge Wells a week or two back.

The Pigeons were beautiful, and must have given the Judge much trouble. The cup for the best pen went to a good Red Pouter of Mr. Yardley's. The first-prize Black Carrier was grand in head and wattle, and well first. Antwerps were a fine lot, making twenty-six pens. The winner was a Blue, very good in colour and strong in wing. Tumblers were beautiful, Mr. Baker's being a little gem. A pretty White won in Fans, second going to a charming Blue. The Variety class was a fine collection, a good White Jacobin first, second a lovely White Owl, third a fine Trumpeter. 459 (Vander Meersech) a capital Yellow Turbit; but the whole class was lovely, and every pen might well have been highly commended, and saved the Judge trouble when once he had picked out the winners.

Rabbits were a good collection. The cup went to Lops. The winner was a good Yellow, measuring 23½ by 4½ inches. Angoras and Himalayas made very good classes. In the Variety class a fine Belgian Hare won the first prize. The quality of the whole Show was good.

**DORKINGS.**—Coloured.—1, R. Cheesman, Westwell, Ashford. 2, J. Ivery and Sons, Dorking. 3, F. May, Reigate Hill. *Chickens*.—1 and Cup, E. Bice, Sandwich. 2, J. Taylor, Dorking. 3, P. Roffey, Betchworth. *he*, J. Taylor; H. A. Rign, Sevenoaks (3).

**DORKINGS.**—Silver-Gray.—1 and 2, Withheld. 3, L. Wren, Lowestoft. *Chickens*.—1, F. Cheesman. 2, E. W. Southwood, Fakenham. 3, A. Glover, East Grinstead.

Pratt, Oxford.

**GESE.**—1, G. H. Fitz-Herbert. 2 and *he*, Marchioness Camden. 3, F. Haines. *Turkeys*.—1, Marchioness Camden. 2 and 3, F. Warde.

#### PIGEONS.

**CARRIERS.**—Cock or Hen.—1, H. M. Maynard, Holmewood. 2, J. Baker. 3, H. Yardley, Market Hall, Birmingham. *he*, T. K. Cucksey, Reigate; J. James, Bath. *he*, J. James; T. K. Cucksey; J. Chandler. c, S. Livermore; J. Chandler.

**ANTWERPS.**—Homing.—Cock or Hen.—1, F. Bartlett, Southampton. 2, G. Bentley. 3, J. Francis. *he*, W. S. Marsh; W. G. Flanagan, Boding. *he*, A. Christy (4); W. R. Pratt. c, M. Sandford; A. Christy; W. G. Flanagan.

**POUTERS.**—Cock or Hen.—1, H. Yardley. 2 and 3, J. Baker. *he*, W. G. Flanagan; G. Holloway, jun., Stroud.

**TUMBLERS.**—Cock or Hen.—1 and 2, J. Baker. 3, G. Holloway, jun. *he*, W. R. Pratt; A. & W. H. Silvester (3).

**FANTAILS.**—Cock or Hen.—1 and 2, J. Baker. 3, H. M. Maynard. *he*, H. M. Maynard; L. G. Morrell; W. G. Flanagan; L. G. Morrell; A. A. Vander Meersech.

**ANY OTHER VARIETY.**—1, A. A. Vander Meersech. 2 and 3, J. Baker. *he*, H. M. Maynard; A. & W. H. Silvester (3); J. James; A. A. Vander Meersech (3); J. T. Herbert, Cleveland Street, London. *he*, A. A. Vander Meersech (3); E. Durrant, Tunbridge Wells; E. Goodwin; J. T. Herbert (3); H. Yardley.

#### RABBITS.

**LOP-EARED.**—Buck or Doe.—1 and 2, C. King, St. John's Wood, London. 3, J. Barker, Louth. *he*, R. Shepherd, St. John's Wood, London. c, C. King.

**HIMALAYAN.**—Buck or Doe.—1, J. Barker. 2 and 3, G. W. Greenhill, Ashford. *he*, R. A. Bolester; J. E. Pilgrim, Hineley.

**SILVER-GRAY.**—Buck or Doe.—1 and 2, J. Quirk, Seymour Place, London. 3, C. King. c, R. A. Bolester.

**ANGORA.**—Buck or Doe.—1 and 2, W. J. Martin, Wimbledon. 3, T. & E. J. Fell, Blackburn. *he*, R. A. Bolester. c, G. Chandler, Edeburgh.

**JUDGES.**—Poultry: Mr. Edward Hewitt, Sparkbrook, near Birmingham; Mr. Richard Teesbay, Fullwood, near Preston. *Of Pigeons and Rabbits*: Mr. George Billett, Southampton.

### MIDDLESBROUGH BIRD SHOW.

THE fifteenth annual Exhibition of Canaries, Mules, British Birds, &c. (open to all England), was held in the Odd Fellows' Hall, Middlesbrough, on Friday and Saturday, October 22nd and 23rd. Belgian birds were scarce at this show, but there were many fine specimens of the Norwich, Lizard, and Yorkshire Canaries exhibited, the latter breed making up nearly one-fourth of the entire Show. Mules and British birds were very good. In Class 38 there were a Nightingale and White Blackbird shown. The influx of visitors was not large, rain falling on the Saturday. 371 birds were shown, somewhat more than at Darlington, but still the quality of birds generally was not better.

**BELGIAN.**—Clear or Marked Yellow.—1 and 2, J. Horn. 3, J. Moffatt. **NORWICH.**—Clear Jonque.—1 and *he*, J. Athersuch. 2, G. & J. Mackley. 3, Brown & Gayton. *he* and c, J. Adams. *Clear Buff*.—1, G. & J. Mackley. 2 and 3, J. Athersuch. *he*, Brown & Gayton. *he* and c, J. Adams.

**NORWICH.**—Evenly marked Jonque.—1 and 2, G. & J. Mackley. 3, T. Clemenson. *Evenly marked Buff*.—1, J. Adams. 2, G. & J. Mackley. 3, J. Stevens.

**NORWICH.**—Ticked or Unevenly-marked Jonque.—1, J. & J. Mackley. 2 and 3, W. & C. Burniston. *he*, J. Athersuch. *Ticked or Unevenly-marked Buff*.—1 and 2, G. & J. Mackley. 3 and *he*, J. Athersuch. *he*, J. Adams.

**NORWICH.**—Crested Yellow.—1, G. Cox. 2, W. J. Hampton. 3, J. Torr. *he*, T. Clemenson. *he*, F. Woodward. c, G. & J. Mackley. *Crested Buff*.—1 and 2, G. & J. Mackley. 3, S. Stratford. *he*, R. Hawman; J. Athersuch. *he*, J. Adams. F. Woodward. c, W. J. Hampton.

**COPPY CREST.**—1, R. Hawman. 2, J. & H. Garbutt. 3, J. Baxter. *he*, J. & J. Wilkinsons. *Evenly marked Buff*.—1 and 2, J. Thackrey. *he*, S. Bunting. *he*, S. Bunting. *he*, J. Athersuch. *Silver-spangled*.—1 and 2, R. Ritchie. 3, S. Bunting. *he*, S. Bunting, Clemenson & Ellerton. R. Ritchie. *he*, W. & C. Burniston. *Gold or Silver-spangled, Broken Cap*.—1 and 2, S. Bunting. 3 and *he*, R. Ritchie. *he*, Clemenson & Ellerton. R. Ritchie. T. Clemenson. c, J. Adams.

**CINNAMON.**—Jonque.—1 and *he*, J. Athersuch. 2 and 3, J. Adams. *he*, M. Burton. *Buff*.—1, 2, and 3, J. Adams. *Variegated Yellow or Buff*.—1, L. Bell. 2, W. & C. Burniston. 3, Brown & Gayton. *he*, L. Bell; G. & J. Mackley; M. Burton. *he*, J. Wilkinsons.

**YORKSHIRE.**—Clear Yellow.—1 and 2, J. Thackrey. 3, J. Wilkinsons. *he*, Johnson & Harston (3). *he*, O. Johnson, W. Lickley. *Clear Buff*.—1, 2, and 3, J. Thackrey. *he*, Johnson & Harston, G. Turner (3), G. & J. Mackley. *he*, M. Corner.

**YORKSHIRE.**—Evenly marked Yellow.—1, 2, and 3, J. Thackrey. *he*, L. Bell. *he*, J. Wilkinsons. *Evenly marked Buff*.—1 and 2, J. Thackrey. 3, R. Pearson. *he*, J. Wilkinsons, L. Bell. *he*, R. Pearson. c, J. Wilkinsons.

**YORKSHIRE.**—Ticked or Unevenly-marked Yellow.—1, R. Pearson. 2, Johnson & Harston. 3, J. Thackrey. *he*, J. & H. Garbutt, W. & C. Burniston. *he*, J. & H. Garbutt, J. Wilkinsons. c, J. & H. Garbutt. *Ticked or Unevenly-marked Buff*.—1, J. Thackrey. 2, Lancaster & Mellor. 3, Fawcett & Anderson.

**CANARY.**—Clear Green.—1 and 2, Armstrong & Redhead. 3, R. Pearson. *he*, R. Pearson. *Evenly marked Goldfinch and Canary*.—1 and 2, J. Stevens. 3, R. Hawman. *he*, J. Horn. *he*, S. Bunting (3). *Dark Goldfinch and Canary*.—1 and 2, Brown & Gayton. 3, J. Stevens. *he*, J. Bexson.

**LINNET MULE, NEAREST CANARY.**—1, J. Stevens. 2, Lancaster & Mellor. 3, J. Baxter.

**MULE.**—Dark Linnet and Canary.—1, J. Stevens. 2 and 3, Lancaster & Mellor. *he*, G. Cox; T. Tegginswood. *he*, J. Baxter.

**MULE.**—Any other class.—1, J. Baxter. 2, W. Carrick (Greenfinch Canary). 3, W. Carrick (Goldfinch Mule). *he*, S. Bunting (3). *he*, J. Stevens. c, R. Hawman.

**GOLDFINCH MOUTDED.**—1, S. Bunting. 2, W. Batchelor. 3, Clemenson and Ellerton. *he*, H. Neilson.

**BROWN LINNET.**—Brown.—1 and 2, W. Carrick. 3, R. Hey. *he*, R. Pearson. 3, W. Carrick. *he*, J. Bage.

**SULLYFINCH.**—1, J. Rowland. 2, H. Neilson. 3, W. Carrick.

**ANY OTHER VARIETY OF BAVIER BIRD.**—1, J. Hutton (Nightingale). Extra 1, R. Hargreave (White Bird). 2, W. Smithson (Bird). 3, J. Green. *he*, J. Green. *he*, J. E. Barr (Mountain Finch). W. & C. Burniston. *he*, M. Burton.

**SELLING CLASS.**—1, J. Stevens. 2, J. & H. Garbutt. 3, W. & C. Burniston.

who, J. Thackrey, Brown & Gayton. *Ac*, J. Adams, J. Young, S. Stratford, Brown & Gayton, T. Tenniswood. *c*, J. Armstrong.

Mr. Thackrey won the President's Cup with thirty-one points, and Messrs. Mackley won Mr. Ouncillor Collingwood's Cup, gaining twenty-nine points.

JUDGE.—Mr. Blakston.

## OXFORD POULTRY SHOW.

THIS Show opened on Wednesday and closes this evening. The quality is very good, and most of the classes contain magnificent birds. The judging is in many cases hardly satisfactory, but we are able to state from actual knowledge that the greatest pains were taken by the Adjudicators. We give the poultry prize list, and next week will furnish a full and critical report of the whole Show. Prince Leopold's champion cup was won by Mr. Burnell with a grand pen of Silver Dorkings.

**DORKINGS.**—Coloured.—1 and 2, Viscount Turn ur. 2, E. W. Beasley. 4, F. S. Arkwright. 1 local, J. Gee. 2 local, H. Piper. *Ac*, T. O. Burne, 1, E. W. Beasley. J. Walker. Rev. H. F. Hamilton, S. Newick. J. White. *c*, O. E. Cresswell, Countess of Dartmouth, F. Caws.

**DORKINGS.**—Silver-Gray.—Cup, T. O. Burnell. 1, F. Cheesman. 2, O. E. Cresswell. 4, W. W. Rutledge. 1 local, E. Woodford. 2 local, W. Bateman. *Ac*, W. W. Rutledge. *c*, S. Salter.

**DORKINGS.**—White.—1, Mrs. M. A. Hayne. 2, O. E. Cresswell. 3, Miss E. Williams. *Ac*, Countess of Dartmouth. 2, R. Gamon. 2, Countess of Dartmouth. 3, A. Chulwin. 1 local, J. T. K. Castoll. *c*, H. H. Young.

**SPANISH.**—E. Jackson. 2, T. Moore. F. W. Notlage. 1 local, H. Johns. 2 local, E. Woodford. *Ac*, H. Wilkinson, J. Walker. S. L. Edwards, W. Blower. *c*, Mrs. Allsopp, E. Winwood.

**COCHINS.**—Cinnamon or Buff.—1, Mrs. A. Tindal. 2, Mrs. Allsopp. 3, A. Darby. 1 local, J. Gee. 2 local, W. R. Pratt. *Ac*, Simpson & Dodd, Mrs. A. Tindal. *Ac*, W. R. Pratt. *c*, M. Allsopp.

**COCHINS.**—Partridge.—1, T. Tadmam. 2, Mrs. A. Tindal. 3, F. Bennett. *Ac*, R. P. Percival, Mrs. A. Tindal, G. Lamb.

**COCHINS.**—Black.—1, G. Forley. 2 and 3, A. Darby.

**COCHINS.**—Any other variety.—1, Mrs. A. Tindal. 2, J. K. Fowler. 3, R. A. Boissier. 1 local, J. W. Craddock. *Ac*, R. A. Boissier. A. F. Faulkner.

**BRAMHMS.**—Dark.—1, R. P. Percival. 2, H. Lingwood. 3, Hon. Mrs. A. B. Hamilton. 4, Newham & Mans. 1 local, R. P. Percival. 2 local, E. Ayre. *Ac*, F. Bonner. *c*, Hon. Mrs. D. B. Grant (3), W. Birch.

**BRAMHMS.**—Light.—1, H. Chawner, jun. 2, H. Stephens. 3, Horace Lingwood. 4, E. E. Horsfall. 1 and 2 local, G. O. Smith. *Ac*, S. Lucas. *Ac*, P. Haines. Capt. W. Saville. *c*, Mrs. S. Crook, G. W. Pether.

**GAMES.**—Black-breasted Red—Cockerel.—1, P. Westcott. 2, G. Lucas. 3, S. Matthews. Local Cup and 2, R. J. Pratt. *Ac*, G. Smith. Pullet.—1, T. P. Lyon. 2, Hon. and Rev. F. Dutton. 3, G. Newgate. 1 local, R. J. Pratt. 2 local, W. R. Pratt. *Ac*, Hon. and Rev. F. Dutton. *Ac*, Hon. and Rev. F. Dutton. 3, H. Tyte. *c*, Hon. and Rev. F. Dutton.

**GAMES.**—Brown-breasted and other Reds—Cockerel.—1, S. Matthews. 2, T. Dymon. 3, J. & E. Prinos. 1 and 2 local, Miss Osborne. *Ac*, R. Ashley, W. Perrin. G. F. Ward. *c*, R. Ashley, W. Grant. Pullet.—1, E. Garnet. 2, J. Peet. 3, S. Matthews. 1 local, Miss Osborn. 2 local, S. Field. *Ac*, E. Garnet. W. O. Phillips. *c*, J. Nelson, H. Lotan, J. Jeken, G. F. Ward.

**GAMES.**—Any other variety—Cockerel.—1, S. Matthews. 2, H. & W. Mason. 3, E. H. M. R. 4, W. O. Phillips. 1 local, H. Lotan. *Ac*, T. Hall. H. Beldon. J. F. Walton. E. Bell. Pullet.—1, U. W. J. Thomas. 2, S. Matthews. 3, J. Goodwin. 1 local, W. R. Pratt. *Ac*, J. Mason. *Ac*, J. Forsyth, J. F. Walton, H. & W. Mason. G. F. Ward.

**HAMBURGERS.**—Gold-pencilled.—1, Duke of Sutherland. 2, O. Judson. 3, W. Tiekner. 1 local, J. T. K. Castoll. 2 local, G. Newman. *Ac*, O. E. Cresswell, J. Walker. W. Clayton, J. Dowken, Duke of Sutherland. *c*, H. Pickles.

**HAMBURGERS.**—Silver-pencilled.—1, H. Pickles. 2, Beldon. 3, E. W. Bracewell. *Ac*, J. Shephard, T. Hanson, Duke of Sutherland.

**HAMBURGERS.**—Gold-spangled.—1, Duke of Sutherland. 2, H. Beldon. 3, H. Pickles. 1 local, J. Calcutt. 2 local, F. J. Knott. *Ac*, J. Long.

**HAMBURGERS.**—Silver-spangled.—1, H. Pickles. 2, H. Beldon. 3, Ashton and Booth. 1 local, J. Stoddart. 2 local, Miss Owen. *Ac*, T. Dean, S. W. Hallam. J. Carr, J. Long. *c*, J. Fielding, G. O. Holt.

**HAMBURGERS.**—Black.—1, J. Pickup, jun. 2, Rev. W. Serjeantson. *c*, C. D. Farrar. 1 local, S. Woodford. 2 local, Miss A. Binney. *Ac*, H. Hoyle, Rev. W. Serjeantson, J. Long. *c*, H. Beldon.

**POLAND.**—Black, with White Crests.—1, P. Unsworth. 2, T. Norwood. 3, A. Darby. *Ac*, T. Edwards, J. Fearnley.

**POLANDS.**—Any other variety.—1 and 2, G. O. Adkins. 3, A. W. H. Silvester. *Ac*, H. Beldon, P. Unsworth, Miss P. Galloway, G. J. Lenny.

**HOUDANS.**—Cup, W. H. Copplestone. 2, W. O. Quibell. 3 and 1 local, R. Harvey. 4, R. Wood. 2 local, R. Harvey. *Ac*, R. Dring, R. E. Kyrr. Penrose. R. Foster. Miss H. A. Woodman. W. O. Quibell. W. Dring. P. Hanson. G. Day. R. B. Wood. E. Handley. C. Morris. *c*, J. H. Baby.

**FRENCH.**—1, E. Burnell. 2, W. Dring. 3, G. de Faye. *Ac*, R. B. Wood. *Ac*, Rev. J. G. B. Knight (3), E. Burrell, W. Cutlack, jun., R. Garnett, J. S. Maggs, H. Feast.

**MALAYS.**—1, Miss A. Brooke. 2, W. B. Payne. 3, Rev. N. J. Ridley. *Ac*, J. Hinton. G. Burnell, Capt. O. Terry.

**AMERICAN FOWLS.**—Brown Leghorns.—1, R. J. Foster. 2, A. Kitchen. 3, S. L. L. Bradbury. *Ac*, A. Kitchen (4), J. Thorneley, F. S. Green.

**AMERICAN FOWLS.**—Any other variety.—1 and 2, E. Burnell. 3, A. Ward. 3, R. R. Fowler.

**SILKIES.**—1, A. Derby. 2, Mrs. J. T. Holmes. 3, E. S. S. Woodgate. *Ac*, R. S. S. Woodgate, H. Stephens. *Ac*, O. E. Cresswell, J. N. Nicholls.

**ANY OTHER VARIETY.**—1, A. Bond (Sultans). 2, H. J. Lonnor (Black Minorcas). 3, M. G. Palmer (Geese). 4, O. E. Cresswell (White Guinea Fowl). H. Beldon, T. A. Bond (Sultans), J. Croote (Minorcas), H. Pickles.

**GAMES.**—Black Reds.—1, E. Brownlie. 2, E. Ardagh. 3, W. Adams. *Ac*, J. Nelson, G. Maples, jun., G. Hall. *c*, E. Morgan.

**GAMES.**—Brown and other Reds.—1, S. Beighton. 2, G. Hall. 3, J. Nelson.

**GAMES.**—Any other variety.—1, E. Brownlie. 2, F. Steel. 3, R. Brownlie. *Ac*, J. Nelson, G. Hall.

**BANTAMS.**—Black, Clean-legged.—1, W. H. Shackleton. 2, C. & J. Hingworth. 3, W. H. Shackleton. *Ac*, Bower & Horsfall, G. S. Prentice, R. H. Ashton. *Ac*, Pearson & Taylor, G. W. Gedney, H. Beldon, E. Cambridge. *c*, C. Reed.

**BANTAMS.**—Sebright.—1, M. Leno. 2, J. W. Lloyd. *Ac*, E. Pritchard; Rev. G. F. Hodson. *Ac*, Rev. F. Tearle, J. W. Lloyd, M. Leno. *c*, J. Walker.

**BANTAMS.**—Any other variety.—1, H. E. Smith. 2, T. Green. 3, E. Cambridge. *Ac*, R. A. Boissier, T. Cropper. *c*, C. Judson, G. Ellis, S. Crooke, T. Cooper.

**DUCKS.**—Aylesbury.—1 and 2, J. K. Fowler. 3, Mrs. A. Tindal. *Ac*, T. Kingsley. J. Walker. *Ac*, T. Kingsley. J. Hedges. *c*, J. O. Fraser, H. T. Sotham, Duchess of Marlborough, J. Rogers.

**DUCKS.**—Rouen.—1, J. Nelson. 2 and 3, J. Brookwell. *Ac*, W. H. Copplestone. *Ac*, J. Walker, J. Hey, E. Shaw, J. K. Fowler. *c*, Duchess of Marlborough.

**DUCKS.**—Black East Indian.—1, G. S. Sainsbury. 2, J. Walker. 3, J. W.

Kelleway. *Ac*, G. S. Sainsbury, E. T. Felham. *Ac*, J. W. Kelleway, Mrs. M. A. Hayne, T. Moore, W. Serjeantson.

**GESE.**—1, R. E. Fowler. 2, J. Walker. 3, J. H. Nicholls. *Ac*, R. E. Fowler, *Ac*, Duchess of Marlborough, J. Hunt. *c*, T. Kingsley.

The Judges were Messrs. E. Hewitt, Sparkbrook, Birmingham; R. Teebay, Fulwood, Preston; P. H. Jones, Fulham; and F. Esquilant.

## THE HONEY SEASON.

THE honey season of 1875 being now over, I am in a position to state the results in this part of the country (East Lothian). The description given by some of your correspondents of the season in other counties applies equally to this. Though we had plenty of spring flowers the weather was such that the bees could not go out, and it was the beginning of May before they made any progress; then they made a good start, and increased rapidly, so that swarms were obtained on the 17th of May in some cases. Then we had cold weather, and had to feed to keep up the breeding. This requires to be done judiciously, not to give too much, but just enough to keep the queen laying eggs.

The season still being unfavourable it became evident that if we wanted honey we must not increase our stocks, but keep them strong. Having fourteen I only increased to seventeen. I only took one super of clover honey, 21 lbs. weight, from a stock which did not swarm. They were sent to the heather on the 29th of July, and brought home on the 8th of September. The hives were in good condition with plenty of bees, and we expected a good supply of honey. The heather was in good condition, but the weather was much against them. They had not more than ten good days for work, and as I had them all weighed before they were sent away and when they came back, I found the average weight of honey gathered was a little less than 21 lbs. each, the lightest being 9 lbs., and the heaviest 39 lbs. This large increase, however, I must own was owing, as I suspect, to a neighbour's hive having swarmed and gone into it a few days after it went to the heather. It was in a Stewarton with two stock boxes and a super, and I had to add another stock box to give room. My other hives were Woodburies, ten, twelve, fourteen, and twenty-two bar frames, in wood and straw, and the common straw hives with flat tops.

Though 21 lbs. is a good average, we did not obtain many well-finished supers. It seemed as if the queens had ceased breeding shortly after they went to the heather, when the honey was deposited in the breeding cells, and the supers were in many cases left empty. I had a twenty-two bar hive having two entrances, and in order to make sure of a super I filled two ten-bar Woodbury hives with the combs and bees, placed the one on the top of the other without an adapting-board, and put on a super. With the exception of the two outside bars which I kept out, which was fine clear honey, all the other combs were well filled with brood in all stages. I made sure of a well-filled super, but alas! I was disappointed. Though 22 lbs. of honey were gathered—being 84 lbs. when I sent it away, and 106 lbs. when it returned—not above 4 lbs. were in the super. I removed the upper hive, driving out all the bees into the under one, and found it weighed 56 lbs.; in fact, every comb was filled with honey, showing that breeding had ceased shortly after they reached the heather.

We put little value on run honey here; in fact, it cannot be sold at hardly any price; 8d. a-pound for the very finest is all that can be had, and it is not worth the trouble of running it for that price. So that our aim here is to have supers from 10 to 15 lbs. each at a time when 1s. 4d. to 1s. 6d. a-pound can be obtained for them.

Large hives are not generally used here; they have been often tried, but those who keep to the small straw hives are in most seasons successful in obtaining supers. A ten "bar Woodbury" is considered very large, but I must confess that we are on most occasions beat by the small skeps, 14 inches wide and 8 inches deep. A neighbour this year began with two stock hives; he has now four hives, and took good 6-lb. supers from the four, and plenty of honey to keep the stocks during winter, so that it is absurd to advise large skeps for every locality. I have no doubt that large hives are required in some places, but certainly not in all, as we have experienced for the last thirty years. We find they do as well in wood as in straw skeps. At one time I thought otherwise, but now, though I have still some straw Woodburies, I would not get any more; and a neighbour here, who keeps about one hundred hives in the season, has nearly all his made of wood, of octagon shape, 18½ inches wide and 8 deep, inside measure. Though treated all in the same way, it has happened for two years that those in the wooden boxes have swarmed first and generally done better than those in the straw. By this experience I do not mean to assert that wood is better for bees

than straw; all I maintain is, that wood is ultimately the cheapest, and that they do as well in the one as in the other. Besides, when the wood becomes black and dirty in the inside we give them a coat of white-lead paint, and the bees take to it as well as to either clean wood or straw. I paint my straw Wood-burys as they get dirty in the inside, so that we really find that the bees are not so fastidious about their domicile as we would have them to be.

My neighbour began with forty-eight stocks this spring, and increased to seventy; these he will reduce to about the same number by breaking up old skeps and destroying old queens, adding the bees of course to weak hives. His success this year has been much the same as my own, though he does not weigh them. Through an accident which prevented him following his occupation as a blacksmith he has taken to keep bees, but finds it a very precarious source of income, and no one can manage them better than he does. If the seasons were always favourable he might be more prosperous, but if money is to be made by bee keeping in other localities it certainly is not in this, and he often longs to be where those flourishing balance sheets are made up, where he would make a fortune in a few years, and being an enthusiast in bee-culture, wonders that anyone would continue in any other occupation when so much can be made by keeping bees. Seeing the great advantage of a moveable bar hive, he would use no other were it not their first expense.

I have just received and introduced two Ligurian queens which Mr. Neighbour sent me. I followed out the printed instructions sent with them. After being enclosed in the cage for two days and two nights I took out the bar and allowed some of the bees to have access to the queen, when I found they would have killed her, although there were no eggs in the hive. The second one being tried in the same way the bees took to her at once, and she was allowed to go free among her new subjects. On the third day I again allowed the bees to have access to the first queen, when they received her with joy.—ALEX. SHEARER.

**WEST GLAMORGANSHIRE AGRICULTURAL SOCIETY.**—Its Poultry Show is on the 9th of December. The prizes are good. One class is unusual—for White Game.

### OUR LETTER BOX.

**HAMBURG COCK'S COMB SHRIVELLED (F. G. H.).**—Give the bird a little ale and toast daily, and rub the comb with camphorated spirit until he has finished moulting.

**COCK-CROWING (—).**—We believe the cocks that crow least are the Dorkings, Crève-Cœur, and Houdans. Cochins, Brahmas, and Game are the noisiest; the two first from their crow, the last from its persistence in challenging. Hamburgs are also very shrill and persistent. It may, however, be borne in mind, that a cock by himself and out of hearing of any other does not crow much.

**BRAHMAS DYING ON THE PERCH (J. C.).**—There can be but two causes for the death of your birds. Either they pick up something that is poisonous, and the red combs would seem to contradict that, or they are too fat. We should incline to the latter opinion, especially as you say they were laying. In straining to get rid of the egg they become apoplectic. It is more than likely they are over-fed. In all cases you can find by handling whether they are egg-bound or not. If they are, dip a wing feather in oil, and pass it gently down the egg passage till it touches the egg, and lubricate it thoroughly. It will be laid and the bird relieved. Feed as follows—barley meal or ground oats alaked night and morning; some whole corn in the middle of the day, and nothing else. Feed only as long as the fowls will run after the food. Your May pullets should lay next month. The cock was suffering from stoppage or from an injury in the back.

**COST OF POULTRY FEEDING (May, Dublin).**—The food to be given to fowls depends on the nature of their run. If they have a grass run, and access to a stable dung-heap, they want less food than when they are either in confinement or shut out from the opportunities of finding natural food. If fowls have nothing but that which is given to them, they should have three meals per day. We believe both for health and economy ground food is better than whole corn. They should then have a meal every morning and evening of barley meal or ground oats alaked with water. This should be thrown down in small places, and given only as long as they run greedily after it. The mid-day meal may be whole corn, or house, table and kitchen scraps. Where the greatest economy is looked for there must be no waste, and every mouthful of food left on the ground is waste. The cost of keeping birds is governed by the condition in which they are when the experiment is begun. If they are in full flesh and condition their appetites will be moderate. If they have been kept on short commons they will eat voraciously at first. If you wish to keep them economically you must superintend the feeding yourself. If you do this, and neither waste nor over-feed, you should keep your birds at from 2d. to 3d. per week per head.

**PROTECTING HIVES (Carolus).**—For a temporary cover put on a piece of carpet and over that a piece of oilcloth. We will publish some drawings of coverings next week.

**BEE FEEDING (T. Meattin).**—In autumn bees should be fed rapidly—that is to say, have all they need for winter in one week. Your plan of giving them what they require every week answers well in spring, but is to be avoided now. Boll loaf sugar in its own weight of water, say a pint of water (or rather less at this season), to 1 lb. of sugar. When the syrup is about blood heat give the bees 2 or 3 lbs. of it every day till they have enough.

**FOX'S SUPREMACY (T. B.).**—It is of no use complaining now of injustice being done at the Crystal Palace Bee and Honey Show. No one can ascertain the considerations which guided the Judges.

**PARROT WITH DISSAISED NOSTRIL (Gardener).**—Ask your chemist to prepare an ointment made up with two or three grains of caustic (nitrate of silver) to about as much fresh lard as will fill a teaspoon, with which you may anoint the part affected. This will tend to allay inflammation and prevent further accumulation of cankerous matter. Give the Parrot a generous diet—some hempseed, if it will partake of it, in addition to other food. Let it have a shower bath occasionally, but after each bath gently dry the bird's feathers before a fire.

**PET SNAIGULL (T. F. Y.).**—The mites in the cage will much irritate the Gull, especially during the night time. The cage will require thorough cleansing. Dress the crevices with turpentine, and afterwards lamp oil or paraffin, and in a day or so afterwards well brush and wash the cage with scalding suds from the washing-tub.

**BREASTROOT LEAVES AND STALKS (J. L.).**—The leaves are cooked like spinach, and the leafstalks like asparagus.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

20th.—A thoroughly wet day from early morning to midnight.  
21st.—Beautifully fine till 3 P.M., then cloudy; lightning at 3.30 and thunder at 8.45 P.M., heavy rain afterwards; but fine night.

22nd.—Hazy early, but fine by 8.30 A.M., then showery; but fine night.

23rd.—Fair, but cloudy early, and after 9 A.M. showery all day; rather less so at night.

24th.—Fine and pleasant all day, particularly bright in the middle of the day.

25th.—Fair, though rather cold in the morning; very fine and pleasant all day.

26th.—Another fine and agreeable day, but not quite so bright as the preceding one; rain in evening.

The first four days wet and uncomfortable, the last three fine. Average temperature nearly the same as the previous week, but falling during the last day.—G. J. SYMONS.

### COVENT GARDEN MARKET.—OCTOBER 27.

THE market is still heavily supplied with all classes of goods, both English and foreign, and with a slow trade prices do not improve. Some good specimens of Salway Peaches are now to be procured, and are making remunerative prices. Both-house Grapes are feeling the effect of the late wet weather, large quantities having been out during the past week, whilst some good samples are still coming from Jersey. Pears consist of Marie Louise, Calabrese Grosse, and Duchesse d'Angoulême, Glou Morcean, and Bourdieu. The first cargo of St. Michael autumn Oranges has just been sold, as also some Pines, so that a regular supply of both may now be expected. Kent Cobs and Fibberts are experiencing a decline, owing to a better supply and the reluctance of buyers to purchase till a lower figure is quoted.

From observations taken near London during forty-three years, the average day temperature of the week is 51.8°; and its night temperature 35.6°.

## MANURE AS A SURFACE DRESSING.

R. LUCKHURST has, on page 87, opened an interesting question, and in advocating the applying manure to the surface of the ground has well sustained his position.

He has told us not only that the practice is good, but why it is good, which is the best of all modes of teaching. I do not propose to consider the theory of the proceeding, but will confine myself mainly to my practice and observation, confirmatory of what Mr. Luckhurst has so well said on the point.

In a village in the north of England a cottager lived until recently who was generally known as an "old cure"—that is a popular name adopted to point out that an individual has peculiarities too numerous to be otherwise laconically described. One of the peculiarities of this "old cure" was his mode of manuring his garden, and planting his Potatoes. His plot was half an acre in extent, and for fifty years and more half of it was occupied with Wheat and half with Potatoes, on the alternate system.

His system of planting Potatoes was to select large tubers and cut them, and to plant each set with the cut side uppermost. His mode of applying manure was to spread the whole of it on the surface after his Wheat was sown and his Potatoes were planted. Year after year he was laughed at, argued with, and advised, but nothing could move him from his plan. Much might be said, and was said, against the soundness of the system—the Potatoes would "go blind," and the manure be "wasted in the air;" but in the end no one could gainsay the fact that not any of his neighbours had better crops than he had. For half a century he did not change his mode of cropping, and applied every particle of manure on the surface after planting, and he left that land as good as he found it. Of that man and his practice were many differences of opinion, but on two points all were agreed—viz., that his crops were good, and that he was an "old cure." The manure I ought to say was rotted, and did not interfere with the work of hoeing and land-cleaning.

Another instance: A cottager, a very near relation of mine—I will not call him an "old cure," but I daresay some people might—was noted for his good garden crops. His plan was to spread the manure on the ground in the winter when in a green, long, unrotted state. By the spring its soluble constituents were washed away, and the surface was covered with littery refuse. On a suitable day this was loosened with a rake, and was set fire to on the wind side to give, as he said, the land a "swinge." Better crops of Potatoes I have never seen than were produced on that man's land. I knew it for twenty years, and to this day he is remembered by his neighbours as having been the "best gardener in the place." He attributed great importance to the "swinge" (scorch), and on this point let anyone try it who may—spread anything over the surface and burn it, and I care not what

crop is afterwards planted, that crop will be benefited by the surface-scorching.

Further: In the garden where I was apprenticed the greatest trouble the gardener had to contend with was his failing crop of Raspberries. The plantation was dug and dunged, and first one manure was tried and then another, but the crop did not satisfy. It was at length determined to procure fresh canes for a new plantation. "Not another bit o' muck should be dug into the old bed, but it might take its chance for a year or two" until the new canes were profitable. That was the verdict passed on the profitless Raspberry quarter. It did "take its chance," recovered, and for ten years yielded profitable crops of fruit. It was never dug afterwards, but manure was applied to the surface. That lesson I have turned to account. For fifteen years I have been responsible for the fruit supply of gentlemen's gardens, and have never dug amongst the Raspas, and never failed to gather abundant crops. Manure has always been applied on the surface.

Ten years ago I took the charge of a garden. It was a light soil in a dry district. The Black Currants appeared to be, as the owner said, "on their last legs." They were at the least twenty years old and produced trashy fruit. They had been regularly dug amongst and manured. The digging was omitted, but not the manuring, and every alternate row was chopped nearly to the ground with the billhook. These stumps pushed fresh shoots, and in two years the rest were cut down. The same trees are now bearing heavily as fine fruit as need be grown. They have never failed, and have never had the spade or fork amongst them, but have been top-dressed with soil and manure. I firmly believe that under similar treatment Black Currants will continue to bear satisfactorily for fifty years; those trees are thirty years old and are better than ever. The same practice I have always followed—that is, never digging, but applying manure on the surface—with Gooseberries and Strawberries, and with the same good results. I found by actual trial that it was the best plan for a dry district and a light soil, and therefore, like the "old cure," I have adhered to it with unvarying success.

But what about vegetables? Well, to every crop, without exception, I have found the application of the manure to the surface during the growing season the most profitable mode of applying it—in fact, without following out the plan I never could have given the satisfaction which I have given in providing an unbroken supply of garden produce over a series of years. Broccoli! why, to dig in manure for this crop I hold to be absolute waste. What does it do? It fosters a sappy stem and flabby leaves for the frost to penetrate. I have always planted this crop thinly in hard unmanured ground, and have trusted to the rains of autumn to give the plants all the support they need before winter. When frost arrives then have I covered the surface thoroughly, and the benefit of that manure is not spent in growing succulent plants for the frost to kill, but in perfecting sweet fine heads for table use. The time will come when all grower:

of Broccoli will work on that principle as being the most rational, certain, and profitable.

Mr. Luckhurst has also mentioned the benefit of surface-manuring when applied to the Vine border. I can also speak unequivocally in favour of the practice. Other growers can, and some do, grow good crops of Grapes without it, but I cannot. I can wish it, and I regard it as my most effective aid in the production of heavy crops of fruit. Further than that, I have had the privilege of seeing the works of better growers than myself, and I have noticed that the best of them are decidedly in favour of rich surface-dressings.

My plain remarks have run to a greater length than I had intended, but possibly the incidents of practice which I have mentioned may stimulate others to adopt the same practice—that is, if they have failed with any crops before, and they fancy their failure is attributable to excessive digging and undue exposure of the surface of the soil, and especially in dry weather.

In penning these lines I wish to say that I am no enthusiast. If, without the practice here narrated the results are satisfactory I advise no change; it is only when an old plan fails that I suggest the trial of a new one.—RADICAL CONSERVATIVE.

## THE ROSE SEASON OF 1875.

### A RETROSPECT.

TAKING it altogether I do not remember a more disappointing season than that which we have just passed through. The bright prospects of the early part of the year were all dimmed by the dry May and June, and the wet weather at the end of June, and the terrible July! How (I speak of Kent) lovely our meadows looked in March, with a prospect of a fine hay crop! But then came weeks and weeks of dry parching wind, and hay is now double the price it was last year. Our Wheat and other cereals were most promising, but the ungenial weather ruined our prospects, and Wheat was rarely ever worse in quality or quantity than about us. Our orchards were a mass of beauty, Cherry trees were especially laden with fruit; but the wet of July caused them to split and crack so that they were not worth gathering, and rotted in quantities on the trees; and lastly, the great crop of our county (Hops) was at one time a very picture of beauty, but hundreds of acres have never been picked, so completely have they gone off; and if there be exceptions to the general failure it is in Nuts, Apples, and the "Turnits" and green crops generally.

Turning to our gardens, there has been much the same story to tell. It was not until the latter part of August that bedding-out was really effective; our small fruits suffered terribly with the wet of the latter end of June and July, and the same causes militated against the Roses. A fair promise was nipped in the bud, and Rose-growers had to mourn over hundreds of blooms which never opened, but were gummed together by the rain, and hence what at one time we were inclined to look upon as the finest Rose season we should have had for some years came at last to be, as in other things, a comparative failure. I say comparative—doubtless we all had fine Roses, but we had also a bloom which lasted but a short time, and which was much diminished in quantity by the rain.

I had the opportunity as judge of visiting most of the great Rose shows, beginning at Exeter on the 18th of June. I was at the Alexandra Park, Crystal Palace, Wisbeach, Spalding, Tonbridge Wells, and Chipping Norton, and the autumn shows of the Metropolitan Floral Society and Stamford. I could not (and, indeed, should not have cared to) go to Birmingham, I was not at Nottingham or Hereford; but with these exceptions I have, it will be seen, been present at most of the Rose tournaments of the season, and should like to record a few things which have struck me as worthy of note.

In the first place I would gladly record the great and increasing interest taken in the Rose. It is not merely that one finds the giants of the ring entering into the contest with keenness and ardour, but that the number of those who are "putting on the gloves" is yearly increasing. Some are coming to the front at what we may call our great national exhibitions, while at the provincial shows amateurs exhibit in a manner which some years ago would never have been dreamt of, and in a way which would make them formidable opponents in a more extended field; while the observations made by bystanders clearly show that it is with no idle meaningless curiosity they scan the stands and take their notes, but with an intelligent interest and desire to increase their already promising collections, and this is, of itself, sufficient to show

the value of our exhibitions. They afford a meeting-place for those interested in the queen of flowers, and hundreds of orders go to growers which but for these exhibitions would never have been sent, and it is for this reason I deplore that the Royal Horticultural Society has abandoned its Rose show for 1876.

In the next place I think the past season has been singularly barren in the production of any new Roses of great merit. A few have come to the front, but only a few; and when one surveys the long list of French Roses with their magnificent promises and their small performance, one cannot but be struck with the great contrast.

*Mademoiselle Marie Cointet* as exhibited at the Crystal Palace by Mr. Bennett of Salisbury was indeed a grand Rose; the brilliancy of colour—a deep carmine pink, its size, and apparent constancy were qualities which, if it be a good grower, promises fairly to make it a favourite Rose. Like others it has been missed in the great rank of foreign Roses; but now it will doubtless be found in all collections and in most of the stands of next year's shows.

*Madame Lacharme*.—I was rated soundly for praising this Rose, yet who that saw the stands of it exhibited at the Alexandra Park and Crystal Palace could refuse to assign to it a high place? Let it be borne in mind, too, that this was an exceptionally bad season for light Roses. As its habit of growth is so very dense it is better to cut out some of the shoots, leaving three or four only on each plant, and by this finer and better blooms will be produced.

*Capitaine Christy*, heralded as a fine Rose, has not been up to the mark, and I have seen but very few good blooms of it; but, again, the season has had something to say to it, for Mons. Norman and such-like Roses have not been at all good. The habit of the plant is good.

There are many other French Roses, such as *Antoine Mouton*, *Comtesse de Serey*, *Ingenieur Madèle*, &c., of which much has been said, but they have not been brought to the exhibition-table in such form as to enable one to say much about them.

I now come to English-raised Roses, of which several have been exhibited in fine condition.

*Duchess of Edinburgh* (Bennett).—This has shared the same fate as most flowers of the same colour—pale pink with darker centre, and I have hardly seen one bloom in condition. I had one plant of it in my own garden, but its blooms were unable to open themselves on account of the wet.

*Duchess of Edinburgh* (Veitch).—Not, I believe, an English-raised Rose, though sent out by an English firm. It was said to be a Tea, but I fail to see in it anything more than a China; and it is, as far as I can judge, simply an improved *Cramoisie Supérieure*.

*Sir Gernet Wolsley* (Cranston).—I have seen some very grand blooms of this product of the King's Acre Nurseries. It is large, of good form and colour; and as the habit is vigorous it will, I have no doubt, be a favourite.

*The Shah* (Paul & Son).—A clear bright red, beautiful in form, not very large, and suitable for the front row in an exhibition stand.

*Wilson Saunders* (Paul & Son).—A very vivid crimson rose. Petals very large, shape good, habit vigorous, and altogether a Rose that will well maintain the reputation of this old-established Rose firm.

*Rev. J. B. M. Camm* (Turner).—Quite a novelty. Wonderful shell-like form and beautifully imbricated; remarkable, too, as being one of the most delicately scented Roses that we have—quite the perfume of the old Oabbage.

*Letty Coles* (Keynes).—This is a very beautiful Tea Rose, a pink *Mademoiselle Willermor*, retaining the form and substance of that fine flower, but of a beautiful bright pink colour.

The third matter that struck me was the great superiority of the seedling Briar as a stock for late exhibition Roses. Whatever may be the opinion entertained as to its merits for Roses in the height of the season, I have no hesitation in saying that nowhere have I seen such Roses as it produces for autumnal blooms. One fact is worth a hundred arguments; and when I was urging on one of our largest exhibitors to exhibit Roses at the Metropolitan Floral Society's show on August 24th, his reply was, "Mine are all over, and Prince is sure to be then in great force." Those who intend to compete at autumnal shows would do well to have a supply of Roses budded on this stock.

My paper has run to my usual length, and I must therefore

close, and may perhaps have some further remarks to make by-and-by.—D., Deal.

### CLAPP'S FAVOURITE PEAR.

FIVE years ago I had sent me a tree with this name, and not knowing it, and the "Fruit Manual" in its last and larger form (replete as it is with very accurate descriptions of the best and most useful varieties of fruit trees, and a very valuable list of synonyms) not including it, I was content to bear with it until this year, when it fruited for the first time. It was sent to me as an "American Pear, early, and of high excellence." The tree is of free vigorous growth with magnificent large healthy foliage, very similar to that fine early autumn Pear *Bourré d'Amanlis*. The fruit is large, oblong-pyramidal, very even in its outline, 4 to 5 inches in length, and 2½ to 3 inches wide; eye open with spreading segments, set in a shallow basin; stalk long, rather stout and curving, inserted in a shallow cavity or with slight depression; skin deep yellowish green, highly reddish-brown on the side next the sun, and when ripe is very beautiful. The flesh is whitish, tender, melting, and juicy, with a sweet, rich, slightly perfumed flavour. Ripe September 10th, 1875, Jargonelle being ripe September 3rd.

Mr. Rivers states in his catalogue of fruits that it was ripe August 20th, 1875, or a difference of twenty days; but then there is the difference in climate to be taken into account. High (over 500 feet above sea level), and exposed on the north-east coast of the North Riding of York, considerable difference in time of ripening between here and Herts may be expected; in fact, Pears are generally late in ripening here. For instance, *Sammer Doyenné* (*Doyenné d'Été*) ripened this year on August 14th, and last year on September 9th; *Jargonelle* this year ripe September 3rd, last year September 25th; *Bourré Giffard* this year September 16th, last year September 23rd; *Bourré d'Amanlis* this year September 24th, last year October 8th; *Williams' Bon Chrétien* this year September 25th, last year October 12th; and *Lonise Bonne* of Jersey and *Comte de Lamy* ripened on October 11th, which last, though a small Pear or only medium-sized, is very delicious, and does well as a pyramid on the Quince. So delicious, indeed, is *Comte de Lamy* that it is a fitting prelude to *Seckle*, which succeeds it, and is the richest of all, and a prodigious bearer as a pyramid.

The tree of Clapp's Favourite is planted at an angle of a wall and upright, part of the branches being trained to a south-west, and the others to a west wall or aspect, and the tree is on the Pear stock. It surpasses *Jargonelle* in appearance, and it, or any other Pear up to *Williams' Bon Chrétien*, in quality, combined with size; it will become a favourite generally with Pear-growers, as it no doubt is, or was, with the one whose name it takes. Of autumn and early winter Pears we have a goodly number; additions are wanted in the early summer and late winter kinds, and among the first of those desiderata must be placed Clapp's Favourite.

Can you tell me what *Jules d'Airolles* is considered to be? Is it synonymous with *Liren d'Airolles*? [They are synonymous.] It is very handsome in appearance, not unlike *Napoleon*, but larger and longer, and very much brighter on the side next the sun.—G. ASHBY.

### LILY OF THE VALLEY FORCING.

No class of plant can be more enjoyable during the dull winter months than the *Lily of the Valley*, but it must then be forced. Single crowns are greatly to be preferred to imported clumps; for when clumps are used you have very few flowers, and these are very inferior to those produced from single crowns. When single crowns are used you have the bloom equally all over the pot, and the spikes of bloom are very fine, and they will well repay the little extra cost, for I have known them to realise at Christmas from 10s. to 15s. per pot in Covent Garden Market. Seventeen crowns are the general number used in 48-sized pots. They should be placed at equal distances apart. Out the roots off to within 2 inches of the crown, and pot them very firmly in any kind of soil, for they will not make any root. Care must be taken to keep the crown above the soil, as it will make quite a week's difference in forcing, for if placed under the soil the plants come irregularly. Place them in a cold frame, and cover them over with cocoa-nut fibre to swell the crowns. Care must be taken not to over-water them, for that causes them to rot off. Bring

them on gradually into heat, and keep the fibre over them till the crowns burst, and then plunge them in bottom heat in a close frame of about 90°. The *Lily of the Valley* will stand any amount of bottom heat. You can bring the plants into bloom in a fortnight, but you will only have flowers and very little foliage, and they look quite as bad without foliage as without bloom. But where bloom only is required it is best to force them quickly, as the bloom is then produced much earlier.—A. Y.

### GRAPES AT THE EDINBURGH SHOW.

I CANNOT go the length of supporting a public testimonial to Mr. Dickson, as "A. K." proposes, though I should be glad to hear his ability and success were recognised by the Royal Horticultural Society—or the "Caledonian," for instance (!); but if he fails to obtain redress from the Edinburgh Society, or rather to get an investigation instituted, I shall be pleased, as an English gardener who is wholly disinterested in the matter and entirely unacquainted with either party, to subscribe my mite to any decided legal action he may be disposed to take in the matter. If, as stated in the letters furnished by Mr. Dickson, the two footstalks of Mr. Curror's cluster were between 2 and 3 inches apart, it can be no hair-splitting problem as to whether it was two bunches or not; they might as well have been cut from different limbs. As to what is a bunch of Grapes, I have my doubts about a fasciated footstalk constituting a legitimate bunch, as I have doubts of fasciated Cucumber—i.e., two adhering together, constituting one fruit; but when the bunches come to be the length of one's finger apart there are no subtleties in the question.—A GRAPV-GROWER.

MR. DICKSON by implication brings a charge of either incapacity or dishonesty against the Judges, and in his letter of the 23rd of September he complains of the conduct of the managers of the Show because he could not commit them to a like imprudence. They knew that they had selected men as judges who had European reputations for both skill and integrity, and to have asked such men to go over their work again in Mr. Dickson's presence that he might see whether their decisions were reliable or not, would have been offering them an insult which every man of them would have repelled with indignation; and because a sense of honour on the part of the managers protected them from such a disgraceful step Mr. Dickson writes, "This seems very strange procedure, and I leave the public to judge from the facts."

Mr. Dickson and those who sympathise with him seem to be under the impression that during the time the bunches were being weighed others than those who had a right to be present were there while he was excluded. This was not so. Dr. Hogg, Mr. Moore of Chelsea, and myself were present as the trustees of the Veitch Memorial Fund, awarding the prizes and medals from that source to the object for which they were offered, and happened to be in the neighbourhood of the two large bunches when they were about to be weighed; Mr. Curror's bunch being close to where I stood, I and my son, who was acting as clerk to the Judges, stepped forward to remove it from the board. I found the bunch attached wholly by one stem to the lateral on which it grew, and not by two, as some writers, who, from the position in which it lay, must have had an imperfect opportunity of observing, else they never could have made the statement that it was attached by two stems. I examined this single stem carefully to satisfy myself that it was hard and fibry enough to admit of a piece of cord my son had in his hand being put round it to form a loop by which to hang it on the hooks of the balance that was to weigh it. This done I lifted it clear off the board with the T piece of wood in my hand and the single stem between my fingers, and held it till it was suspended at the end of the balance, while 26 lbs. made up of various weights were at the other. It turned the scale with that weight against it, and 1 oz. was added. This was its exact weight. It had only lost 3 oss. of the weight rendered by Mr. Curror during the twenty-four hours it had been cut, the greater part of which time it had been in a hot dry room. When this was noted there was a slight cheer, led I think by Mr. Rust of Kridge Castle, near Tunbridge, by way of marking his sense of the honesty displayed by its exhibitor, of whose very existence he had till that moment no knowledge. I removed the bunch from the beam, and replaced it on the board. While this was being done Mr. Dall of Stoke Rochford, one of the Judges, with some one assisting him, removed Mr.

Dickson's bunch, and placed it in like manner, when it was found that with the ounce weight removed it would not balance the 26 lbs.; 1 lb. was then removed, and according to my recollection 10 ozs. added, and not 15 ozs. as some have written. When it was thus discovered that Mr. Dickson was vanquished there was no cheering or manifestation of feeling of any sort, and Mr. Dickson may rest assured that there was no animus against him in any form whatever, but a hope that further effort would lead him to regain the position he once held of being the grower of the heaviest bunch on record.

It is true Mr. Dickson's bunch is said by him to have weighed 26 lbs. 8 ozs. when weighed at home, and while it was unfortunate for him that it lost so much weight on the way, the Judges had nothing to do with that; their duty was to decide according to the evidence placed before them. When these large bunches were placed in the exhibition room Mr. Dickson's was not nearly so compact and well-formed a bunch as Mr. Curror's, and required a great many more strings to keep it in position than the other; but until the Judges were done with it there was no evidence that it had suffered in any way, and I saw it replaced on the board and put back beside the other on the marble slab in front of the mirror in good condition.

In the position they were thus placed in no one could see the stem of Mr. Curror's bunch without getting upon or over a bench of fruit that stood in front of the marble slab referred to, and I fear many observers came to the conclusion that the bunch was two and not one, on no better evidence than the shape of the bunch.

I was most careful in examining both bunches under this head, having been one of the Judges that awarded the prize to Mr. Hunter's great Hamburg bunch at Belfast, where the same plea was set up after the bunch was removed, but not before. On that occasion, as on the recent one, the bunch was a single one attached to the lateral by one single homogeneous stem.

I had written this far when the Journal was handed to me, where I note that you have closed the correspondence about this matter. I, however, hope that as my object is to explain what really was the state of the case, and this from the very best means of observation, that you will insert what I have written; pressing engagements and absence from home prevented my doing it earlier.—W. THOMSON, *Tweed Vineyard*.

### A STANDARD MAGNOLIA GRANDIFLORA.

This grand plant we usually find trained against walls with a south aspect, where its large, bright green, glossy foliage is pleasing all the year round, and during late-summer months its value as a decorative plant is greatly enhanced by its large white fragrant flowers. It is very rarely that we see it grown either as a bush or pyramid, yet I feel confident there are many sheltered nooks in the south of England where, if so grown and treated kindly, it would do well. In the north no doubt it would be impracticable.

We have a standard pyramid growing in the open flower garden here which has attained the height of 26 feet, with branches covering a circle 12 feet in diameter. It has a clean bole 3 feet in length, which at 1 foot from the ground has a girth of 21 inches. It is true the habit of the plant is somewhat straggling, nevertheless it is very much admired by all who see it, more especially when in bloom, and this grand plant is very rarely without bloom from the early part of July until frost arrives. The foliage being so much larger than other evergreens it makes a very striking object, even in the dull months of winter.

This plant speaks volumes in favour of the mildness of the climate of Clevedon, which, by the way, is rapidly becoming one of the most fashionable watering places of the west.—THOS. FOOTZ, *Gardener, Clevedon Court, Somerset*.

### CALADIUM ARGYRITES AND GESNERA CINNABARINA.

ABOUT the prettiest and most effective arrangement possible with two plants, is to form a row of these, plant about. The rich velvety crimson foliage of the Gesnera brings out the striking beauty of this the most beautiful and useful of all Caladiums, and *vice versa*. They are two of the most useful and effective decorative plants that can be grown, and it is a

wonder they are not more grown than they are, being of easy culture and can be dried-off and stored away for nearly half the year, giving next to no trouble. To keep them successfully when at rest the Caladium should not be subject to a lower temperature than 60°.—D. THOMSON (*in The Gardener*).

### OLLA PODRIDA—A CONTINENTAL TOUR.—No. 6.

IN my last I left off at the Lake of Lucerne, from there we returned *via* Basle to Paris. There was not much in a tedious journey between Basle and Paris of fourteen hours' duration to interest any of your readers in a horticultural point of view. One thing that struck me was the immense quantity of Cherry trees that were grown in part of the district that we passed through which were laden with fruit. I believe a great many of these Cherries are grown for the sake of making liqueurs of their kernels. Some of the trees were very beautiful—the fruit of that brilliant red just before approaching to ripeness; and it showed pretty clearly how free the country was from small birds of all kinds that such quantities could be grown in open standards unprotected. The almost total want of animal life of any kind, either of birds in the trees or cattle and horses in the fields, is a great drawback to English taste. We may be, and no doubt are, too much overrun in many places with the British house sparrow, which I am convinced does more harm than good, in spite of all that his numerous admirers may say for him as a destroyer of insects; but we miss abroad our British songsters and robins, and that most useful of all birds the starling; for while mentioning birds I cannot resist a few words of praise of a bird which I believe does more good to the farmer and horticulturist than any other as the active destroyer of wireworm, cockchafer grub, and all larvae of the sawfly tribe.

I need not say much about Paris, as I have already in the pages of the Journal made remarks on the parks and gardens there. I think anybody who went in for the mixed flower-border style of gardening would have their faith much shaken by inspecting the gardens at the Tuilleries and the Luxembourg. Both gardens were planted this year and last in as nearly as possible the same way—about four to six different kinds of plants being used in clumps, as *Ageratum*, *Calceolaria*, *Antirrhinum*, *White Cosmos*, with standard *Lilacs* trimmed to a head, interspersed with a few standard *Roses*. These plants were generally in circles of seven plants, or planted round the standards, and the whole bordered with three rows of *Geraniums*; but these *Geraniums* were planted in a mixed style, as each row was the same, but had four different colours—scarlet, salmon, white, and pink—planted plant for plant in a row, and generally a repetition of the same sorts of *Geraniums*. The effect of whole lines of parallelogram-shaped beds being all planted and bordered the same way was most monotonous. For instance, a large square garden in front of the Tuilleries, between the *Boulevard Rivoli* and the river *Seine*, is divided by two broad paths at right angles to each other in four equal quarters. Each of the four equal quarters has a bed about 6 feet wide going round it, and each of these 6-foot-wide beds was planted, as far as I could see, with identically the same plants and identically the same way, and bordered with these interminable rows of mixed *Geraniums*.

The gardens in front of the *Cafés Chantants* in the *Champs Elysées* were certainly planted in better taste, as here, as a general rule, the beds are large, and contain evergreens and deciduous shrubs, and are bordered by different kinds of bedding plants, each bed generally having only one or two kinds of plants, but used in masses. For instance, a bed of *Rhododendron* edged with three rows deep of scarlet *Geraniums*, with two rows of *Lobelia* in front; and scarlet *Hibiscus* with white-leaved *Geraniums* in front. Here, too, and up the *L'Avenue de l'Impératrice* and in the *Parc Monceaux*, some of the larger-leaved subtropical plants, as *Canna*, *Ricinus*, *Zea*, *Cannabis*, *Caladium*, &c., are used, though my visit was too early this year to see them to any advantage. I can congratulate them, too, on an improvement on their grass in places, especially about the *Champs Elysées*, where the mowing machine is much more freely used; but in the *Parc Monceaux* and in the Tuilleries gardens and Luxembourg they still prefer to let the grass grow for two or three weeks and lay it flat by the hose. The *Parc de Buttes Chaumonts* is capable of being made a very beautiful place if it were not in some respects very artificial with sham concrete rocks and very shallow lakes, and hardly any flowers are made use of; almost the only bed being one of *Valerian*. There is a great opportunity here for large masses of herbaceous plants, and one would like to see it

put in the hands of an able man to select the best kind of plants, as there are many places especially suited for the dwarf alpine plants, as the Sedums, Saxifrages, Auriculas, Cyclamens, &c.; while in others Hollyhocks, Delphiniums, Phloxes, &c., would help to enliven the place.

On the whole the Parc Monceaux is better worth seeing than any other public garden in Paris. It is only small, but there is better taste and more diversity displayed in it than any other. We have here different kinds of Begonias in use; varieties, too, of Coleus, Alternanthera, and other bright-foliated plants. But there is nothing in it in my mind to compare either with Hyde Park, Battersea Park, or the Crystal Palace; and if London had only the climate and, above all, the clearer atmosphere and absence of coal smoke which Paris enjoys, our London parks would still more eclipse anything that any other city can show. We may well take a lesson from Paris in the management of their trees; but whether in our climate, even if our streets were wider, we could grow avenues of trees in the streets as in the boulevards is doubtful. I was glad to see the Plane trees on the new Thames Embankment looking so healthy, and I have no doubt in our more open spaces, where plenty of water is given through a hose to cleanse the leaves, that many other trees would flourish. The markets in Paris at the Halles Centrales are well supplied with flowers and vegetables, and there are also a great many cut flowers sold in the flower market at the Madeleine; but one is struck with the paucity of flowers which are grown in window boxes, and there are not many window plants to be seen about, nor, as far as I can learn, are there many great leading nurserymen with much glass devoted to plant-growing—certainly no establishments like those of Messrs. Veitch, Williams, Henderson, Bull, and others; the chief energy of nurserymen near Paris being devoted to the commoner cut flowers, or smaller plants, as Dracenas, Palms, &c., for dinner-table decoration.

One word as to the French *sécateur*, which I see there is a drawing of in the last number of the *Journal of Horticulture*. I have had three within the last two years, but I find all the work is done with an old pair of common English garden scissors of a full size, which have certainly been in use for more than six years, and with which I can do double the amount of work in pruning Rose trees or bush fruit trees, &c., and much more satisfactorily. The *sécateurs* are dependant on springs to open them, which often get out of order, and they will bear no strain in cutting large shoots.

I will conclude my notes next time with a few remarks on Battersea Park, which I went to twice on my return to England in order to contrast English with foreign gardening.—C. P. P.

### RUSSIAN APPLES.

THE Department of Agriculture did a good thing when it imported from Russia a number of the popular varieties of Apples grown there. In the distribution of scions from those trees some fifteen varieties fell to our share, and the grafts made for them all grew, and are now fine thrifty trees, says Dr. Hoskins of Newport, Vt., and these have been grafted from until we have more than a hundred young trees from this stock. The success of the Tetofsky and Duchess of Oldenburg Apples, which were among the earlier importations from Russia, probably stimulated the agricultural department in its efforts to bring over others; and though it is too soon to do more than begin the record of results, we cannot but be pleased with the thrifty growth of these new varieties and their adaptedness to our cold winters. But two of the varieties received from the department have yet fruited; one, the Yellow Transparent, last season, and another, the Grand Sultan. They are both early autumn varieties, the former ripening with the Duchess of Oldenburg, and the latter early in September. Both are handsome and excellent Apples; the Grand Sultan particularly so, being of the largest size, a bright green in colour, becoming a rich waxy yellow in ripening. The flavour is mild, the flesh very mellow and soft, something like the Maiden's Blush in quality. We shall watch with interest the coming into bearing of all these new sorts, hoping that among them may be found not only autumn but winter varieties, that will prove good and profitable in the colder sections of the State, says our contemporary of the Vermont "State Journal."—(*Boston Cultivator*.)

PREVENTION OF THE CARROT GRUB.—Make your drills in the usual way, only deeper and wider, and nearly fill them with

wood ashes. Sow the Carrot seed thereon, and cover with soil. Such was a friend's advice, and I am glad to say that from that time up to the present I have not had a grub in my Carrots.—C. M. McGrow, *The Gardens, Nash Court, near Faversham*.

### THE CHRYSANTHEMUMS IN THE INNER TEMPLE GARDENS.

ON no previous collection of this finest of autumn flowers, which has for many years been held in the Temple Gardens, has a larger amount of public attention been bestowed than this year. The Gardens are crowded with visitors each day, and will probably so continue to be for the next fortnight, during which time the plants will remain in good condition. The public appreciation of the display must be as gratifying to the Society of the Inner Temple as it is encouraging to their able gardener, Mr. Newton.

The collection includes 450 plants trained on single stems, each bearing from three to six blooms. The plants are plunged in the south border, and are protected by glass and canvas. An opaque background is needed to show the blooms to the greatest advantage, but as at present arranged the collection is worthy of a visit from all who can appreciate vigorously-grown plants, noble flowers, and rich healthy foliage. It is one of the finest of the many fine displays which have preceded it, and Mr. Newton is to be congratulated on the success of his efforts.

It is not possible for all the varieties to be at their greatest perfection on a given day, but most of the standard sorts are now in their prime.

The most striking features of the collection are the perfect blooms of White Beverley; these are particularly massive and possess fine form and high finish. George Glenny, the new sulphur-coloured flower, is in exceedingly good condition, and is evidently a valuable variety. Bismarck attracts a large share of popular attention; it is of a golden amber colour, very large, incurved, with loose petals, and not likely to be enduring. Refulgence is a new variety, not large, but exceedingly rich—surpassing Progne in its glowing velvety surface—it is reflexed, and of a bright crimson-claret colour. King of Denmark, rosy lilac with golden tips, is very effective; and Prince Alfred has immense and perfectly-formed blooms of rosy crimson. There are some grand blooms of Gloria Mundi, and fine examples of bronze and yellow Jardin des Plantes. Guernsey Nugget has blooms nearly 6 inches in diameter, and of the same size are those of Empress of India. Elaine, amongst the Japanese varieties, is conspicuous by its flowing outline and its bluish-white purity; Red Dragon in this section is also noticeable. Garibaldi, a bright chestnut colour, is very fine; and such varieties as Mrs. G. Rundle, Vesta, Prince of Wales, Pink Perfection, Golden Beverley, and Prince of Anemones are, as usual, constant and excellent.

The new edition (the fourth) of Mr. Newton's pamphlet on his mode of cultivating the plants is in great demand; his work recommending him as a sound guide and teacher.

In the Middle Temple Gardens Mr. Dale has also a small display, but owing to extensive building alterations his plants have had to be crowded together, and so have become drawn, and have had no chance to perfect blooms of their usual excellence.

### TREES AND SHRUBS FOR THE SEACOAST.

ON page 388 information is asked as to sea-spray-enduring trees or shrubs. Judging from my own observation of several years on this part of the Anglesey coast I give the first place to Evergreen Oak and Gorse both single and double-flowered. The Evergreen Oak is the finest of all trees for shelter within reach of spray from the sea. It is certainly of slow growth, but neither wind nor spray injures it. Amongst deciduous trees and shrubs of quick growth the best are Sea Buckthorn, Black and White Thorns, Sycamore, and Laburnums.

If I were planting close to the sea for shelter I should put an outer belt of Gorse and Sea Buckthorn intermixed with Blackthorn, followed by an inner belt of Evergreen Oaks. The rapid growth of the Buckthorn would form a useful shelter for the Evergreen Oaks, and enable them to start much stronger than if fully exposed in the first instance. Of Conifers the best is *Pinus insignis*, which is also the handsomest of all the Pinuses. *P. Laricio* is also very useful and of quick

growth, and both will stand a certain amount of spray, but they will not succeed where they "get well splashed with sea spray."—J. ELLAN, *Bodorgan, Anglesey.*

### CARRION FOR VINE BORDERS.

I ENTERED on my duties as foreman in the gardens of Polmaise, near Stirling, in November, 1859, where a range of new vineries and plant houses had been put up about a year previously, the borders being all new at the same time and the Vines one year planted. The borders were made of turf mixed with carrion and broken bones. The first year after planting the Vines seemed to have done fairly well, but I did not think the wood ripened so well as it ought to have done, being soft with a large amount of pith.

When top-dressing the borders in December I observed the roots that were near the surface to be large and fleshy, with strong white-looking points. Many of those roots seemed to be decaying or dying back, and I have no doubt this was the result of their fleshy condition, caused by too powerful a stimulant, being full of sap with no foliage at this time of year to take it up, and consequently being in the very worst condition for standing the winter. The second year after planting there was a little difficulty in inducing them to break evenly; they, however, set and ripened two and three bunches on each rod, averaging about 2 lbs. each.

I left this situation in November, 1860, and had an opportunity of seeing the Vines again in May, 1866, nearly six years after I left, and the Vines nearly eight years planted. At this period, in ordinary circumstances, they ought to have been in full vigour and carrying splendid crops; but I think it would be difficult to imagine Vines to be in a more completely deplorable condition—the young shoots being like good wheat straws, with bunches and berries quite in keeping with the wood and foliage, and this the result, I have no hesitation in saying, of the presence of the too powerful, unnatural, and loathsome stimulant of carrion in the borders.

I think it is well that "INQUIRER'S" employer yielded to his reasoning, notwithstanding that a gardener told him that carrion was a "good thing," and that "Vine roots would go half a mile to it." I certainly would let them have the opportunity of going half a mile to it by burying it that or any other considerable distance from Vine or other fruit tree borders.—J. FAIRWEATHER.

### SHREWSBURY POMOLOGICAL SOCIETY.

THE annual Exhibition in connection with this Society took place on October 17th, and was one of the most successful ever held. The present season has been unusually favourable for the cultivation of fruit, and the Society probably never held a Show where so much was shown and where such uniformity of excellence was apparent. There were altogether 840 dishes of Pears and Apples.

The following list shows how many dishes of fruit each exhibitor showed:—Mr. Wilson of Bletton (nurseryman) 35 dishes of Apples, 25 of Pears; Mr. Thomas Southam (amateur), 18 of Pears, 8 of Apples; Mr. Tomkiss, gardener at Ound Hall (a splendid collection), 50 dishes of Pears, 25 of Apples. Mr. John Wilson of Leaton Knolls showed a fine collection of Pears in 60 dishes, and 50 of Apples. Mr. Whittaker, gardener at Crewe Hall, sent 30 dishes of Pears, all in fine condition and very correctly named. Among the amateurs Mr. E. Cope of Beascham House carried off the palm, and with one dish of Pears certainly eclipsed most of the gardeners. The gardener from Attingham (Mr. Pearson) showed 45 dishes of Pears and 55 of Apples. Mr. Hoskins of Onslow sent a very choice collection, consisting of 28 Pears and 24 dishes of Apples. Mr. Jarvis, the gardener at Ondonover, sent one of the most choice collections in the Show, embracing 75 dishes of fruit. Mr. Stanton's gardener (Mr. Griffiths) showed 20 dishes of Pears and 6 of Apples. Mr. Jukes of The Mount also distinguished himself as an amateur, especially in Pears, of which he had fourteen dishes, and of Apples 7. Mr. Austin of Allscott, Wellington, showed a small but very choice collection of fruit, consisting of 8 dishes of Pears and 7 of Apples. Mr. Condé Howell of Rhieuport, Montgomeryshire, showed a splendid collection of Apples in 22 dishes. The great collection of the Show was that of the Messrs. Oldroyd & Son. It embraced 190 dishes of Pears and 180 of Apples. Every variety of well-known species were shown in splendid condition. We were particularly struck with the show of older Apples, of which there were 21 dishes.

**MONSTER APPLE.**—A fruit grown in a gentleman's garden at Leek, Staffordshire, in the open air on a cordon tree is

15 inches in circumference, and weighs 1 lb. 4 ozs. I believe the name is Lord Nelson.—T. B.

[It is probably Kirke's Lord Nelson.]

### ROYAL HORTICULTURAL SOCIETY.

WE have been requested to publish the following summary of the privileges of the Fellows for the year 1878:—

The privileges of a forty-guinea Life Fellow and Fellows paying four guineas a year with two guineas admission fee, which fee will be remitted in favour of the wives or husbands of deceased Fellows being themselves elected Fellows:—

1. To receive one ticket giving personal admission every day, and to all shows, fêtes, conversations, and promenades, both at Chiswick and South Kensington.
2. To receive two tickets on which shall be inscribed the name of his or her nominees, which shall give personal admission to such nominees every day, and to all shows, fêtes, and promenades, except on such occasions as are specially reserved by the Council.
3. To purchase for members of his or her own household, at the price of £1 1s. each, non-transferable tickets, which entitle the persons whose names are inscribed thereon to all the privileges of personal admission that Fellows themselves possess, except that of admission on specially reserved occasions.
4. To purchase for £2 2s. a garden ticket which will admit all the children of the Fellow who are under twelve years of age, and who must be accompanied by not more than one attendant to every three children.
5. To purchase for £1 1s. each books containing twenty-one orders of admission to the Saturday promenades (for admission to which no money shall, in future, be taken at the gates).
6. To admit, by personal introduction, two friends to the gardens at South Kensington on Sundays.
7. The power of admitting friends daily (Sundays excepted), by written order to the garden at Chiswick.
8. The right of purchasing, previous to the day of the shows or promenades, tickets at reduced prices.
9. The right of obtaining upon application such seeds, plants, and cuttings as the Society may have in sufficient numbers to meet the Fellows' applications.
10. The right of purchasing the flowers, fruit, &c., grown at Chiswick which may not be required by the Council for scientific purposes.
11. To receive, on application in writing, a copy of the publications of the Society.
12. The right of voting at all meetings of the Society.
13. The right, on giving notice in writing, of being relieved from the yearly payments while resident abroad.
14. Free admission to the reading-room and Lindley library.

The privileges of a twenty-guinea Life Fellow and Fellows paying two guineas a year with two guineas admission fee, which fee will be remitted in favour of the wives or husbands of deceased Fellows being themselves elected Fellows:—

15. Entitled to one yearly ticket, not transferable, admitting the Fellow every day, and to all shows, fêtes, conversations, and promenades, both at Chiswick and South Kensington.
16. Entitled to the privileges mentioned in Nos. 5, 7, 8, 10, 11, 12, 13, and 14.
17. To half the privileges mentioned in No. 9.
18. To admit by personal introduction, one friend on Sundays to the gardens at South Kensington.

Tickets at £1 1s. per annum admitting to all shows, scientific meetings, and lectures of the Society (but not to Promenades), and to the Chiswick Gardens on week days, will be issued to *bona fide* gardeners recommended by two Fellows.

All former Fellows of the Society who withdrew therefrom (after having paid all subscriptions due from them to it), will not be required to pay a fresh entrance fee if they shall be re-elected in the year 1876.

### GARDEN SCISSORS—CARROT AND ONION GRUBS.

THE *sécateur*, or French pruning shears, is no doubt "a very handy little instrument," but I think the old pruning scissors are much more "handy." The length of the *sécateur* which I have is a little more than 7 inches, but the opening of the cutting part being so nearly wedge-shaped the branches pass along it to near the point before being severed, consequently there is much less leverage, and more power is required to cut them off. The old pruning scissors which I have are a little more than 6 inches long, but the opening for cutting being more crescent-shaped or hooked, and much nearer the rivet or screw, has a much greater leverage. I find them much easier to work, and they will cut off much thicker shoots than will

the *secateur*. With these instruments the operator will do more work, but they are not equal to the knife for a clean cut. The knife does not crush the bark and wood as pruning scissors and all such-like pinching instruments must of necessity do.

A few words about "grubs," which have been written about in late numbers of the Journal. Several years ago our Carrots were very much eaten by them. In November of last year they were so eaten that I gave the ground intended for Carrots the following season a good dressing with quicklime, scattering it in the trenches as it was dug. At the time of sowing, after drawing the drills and sowing the seed, I sowed a mixture of soot and wood ashes in the drills, and the Carrots are this year perfectly clean, scarcely a grub-eaten one to be found in the bed. I consider soot and wood ashes (or the ashes made of burnt garden rubbish of any kind) one of the best things that can be used. I invariably mix it with the soil in which I sow Broccoli and such-like seeds, also where I prick them out, and do not have one clubbed plant in a hundred.

I would recommend those who are troubled with the Onion maggot to trench their Onion ground 18 inches deep as early in January as possible, putting in plenty of fresh manure, if direct from the stables so much the better; if pig-dung can be procured it is to be preferred to all others. Dig over the surface of the ground 3 or 4 inches deep a few times in dry weather during the spring; do not sow too early; keep a sharp look-out for the maggot, and if it should make its appearance at once sift some rather fine coal ashes all over the beds about half an inch thick; water with liquid manure twice a-week unless it is a very wet season, then I think there will not be many Onions eaten by the maggot.—D. WALKER, Gardener to B. H. Collins, Esq., Duncormick.

### NOTES AND GLEANINGS.

THE GREAT SHOW OF FRUIT AND CHRYSANTHEMUMS to be opened at South Kensington on the 10th inst. is expected to be a great success. The decision of the Council to keep the Show open for two days, to light the conservatory and arcades with gas, and to admit the public from 6 to 8 P.M. on the first day, and from ten to four o'clock on the second day, on payment of 1s., is a step which can hardly fail to meet with public appreciation. The prizes are all to be paid without any rebate on this occasion, and thus the utmost encouragement is given to exhibitors as well as to the public to inspect their productions.

THE USUAL MONTHLY DINNER of the Horticultural Club will be held at the club house, Adelphi Terrace, on Wednesday, November 10th, at 6.15, the day on which the great Fruit and Chrysanthemum Show of the Royal Horticultural Society will be held.

THE following gentlemen have consented to act as JUDGES at Messrs. Suttons' forthcoming ROYAL BERKSHIRE ROOT SHOW:—Professor WRIGHTSON, Professor of Agriculture at the Royal Agricultural College, Cirencester; W. Scott Hayward, Esq., V.P. of the Kingseote Farmers' Club; W. Brinshaw, Esq., Her Majesty's Royal Bagshot Farm; H. Simmonds, Esq., Steward to John Walter, Esq., M.P.; and for vegetables and Potatoes, Mr. Daniels, The Gardens, Swyncombe; and Mr. Lees, The Gardens, Whiteknights.

WE are informed that M. Ed. André is about to depart on a VOYAGE OF BOTANICAL DISCOVERY in South America, and will visit Colombo, Ecuador, Peru, and Brazil. From the labours of such an excellent and energetic botanist the gardens of Europe may hope to secure many valuable additions.

THE Queen has accepted from Mr. Francis George Heath a copy of his new work, "THE FERN PARADISE: a Plea for the Culture of Ferns."

"MARTIN DOYLE," one of the earliest writers who aided us a quarter of a century since, is dead. The Rev. WILLIAM HICKEY, Rector of Mulranee, near Wexford, in Ireland, died on the 24th of October, aged eighty-eight. Besides contributing to our columns and those of other periodicals, he was the author of many useful cheap volumes on subjects connected with the cultivation of the soil and domestic economy. No one has written more home to the needs of the small farmers and peasantry of Ireland.

THE *Irish Farmers' Gazette* announces the death of WILLIAM PLANT, Esq., M.D., at his residence, Plantation, Monkstown, on the 23rd ult. Few names were more familiar to florists than that of Dr. Plant, associated as it has been for more than half a century with the most successful cultivation of his three specialities—namely, Auriculas, Carnations, and

Tulips. As a grower of the first-named he had no superior. To see his Auricula frames, and, above all, his marvellous Tulip beds, in their flowering season, was a sight worth going a long way to see. Roses, also, he was fond of, and grew them successfully; but the Auricula, Carnation, and Tulip were his *passion*. Dr. Plant was, we believe, at his death the oldest member of the Royal Horticultural Society of Ireland, and was for more than forty-five years a member of its Council. He had arrived at the age of eighty-five years.

BATH AND WEST OF ENGLAND SOCIETY.—The usual Council Meeting of this Society was held at the Grand Hotel, Bristol, on the 26th of October, under the presidency of the Right Hon. the Earl of Ducie. The Council resolved that the meeting (Hereford, 1876) shall commence on Whit-Monday, June 5th, and extend over that and four following days; they also settled the stock and poultry prize sheets and implement regulations, but they were ordered not to be published until after the November meeting of the Council, in order that any special prizes offered by the Local Committee may be published simultaneously with those offered by the Society.

### WHAT IS A BUNCH OF GRAPES?

I CONSIDER a bunch, or cluster, of Grapes must proceed from one eye, no matter what form it takes after its exit from the eye—fasciated, elongated, or any form, provided it proceeds from one eye. One may just as well expect two seedling trees from one seed as expect two bunches of Grapes from one Vine eye. Believing this to be the true and simple definition of a bunch of Grapes, I say, unbiassed in any way, that the Eskbank bunch of Grapes was decidedly one bunch. You may call it a big bunch, a monstrous bunch, a beautiful bunch, or an ugly bunch, yet it is simply one bunch or cluster of Grapes.—HENRY KNIGHT, *Floors*.

I THINK there is only one way of deciding the difference between a single and a double bunch of Grapes. I maintain that a single bunch is one that has one clear stem from the wood, and if that stem be only half an inch long and is round and perfect it is really a single bunch, let it have as many shoulders as it may below that. But, on the other hand, if there are two stems issuing distinctly from the wood without being united into one stem they are two bunches; and if Mr. Curror's bunch of Grapes at Edinburgh had, as Mr. Loudon and Mr. Ingram state, quite 1½ or 2 inches clear space between the stems, it seems quite clear that it was two bunches, and as such I should have felt justified in judging them.—THOMAS RECORD.

THE substantial testimony furnished by Mr. Dickson in support of his case has now removed the subject of dispute out of the region of mere assertion. If the Edinburgh Society, or those who may be responsible in the matter, now condone by their silence and inaction what the public must at present regard as a gross miscarriage of justice, they will court a not very enviable reputation among horticulturists. It is not now a controversy between two rival growers, but is a question of public importance, which has increased in magnitude by official silence. Are those who are responsible waiting and wishing the fire to burn itself out, after being a nine-days wonder? As the case stands at present such surmises are at least excusable. I hope, however, the subject will not be allowed to drop.—A GRAPE-GROWER.

A BUNCH of Grapes should grow from a single eye on the rod of last year's growth, and hang by a single stem when exhibited; but if from a double eye there will be two distinct stems, which to all intents and purposes constitute two bunches—alias twins or monstrosities.—W. McPHERSON, *Sneeton Hall Gardens, Ashbourne*.

[All good authorities agreeing in the definition, no more need be inserted upon the subject.—EDS.]

WE do not recollect any subject which has absorbed so completely the attention of the gardening world as has the discussion which has grown out of the Great Exhibition of fruit at Edinburgh. The letters which we have published from some of the first Grape-growers and most able gardeners of the day, together with others which we have received on the same subject, are a sufficient testimony of the state of the horticultural mind on this question.

It is not for us to express an opinion as to the correctness or otherwise of the awards in the class for the heaviest bunch

of Grapes, for it seems to us that the Judges must, as regards that Show, be the sole authorities. It must be remembered that they were invested with full discriminatory and judicial powers. They constituted the highest tribunal of the Royal Caledonian Horticultural Society in determining the legitimacy, so to speak, of the products of every competitor, and were gentlemen of ability and integrity. They, according to rule 6 of the schedule, had power to "withhold" or "modify" the prizes, and from their decision there is no appeal. We must in the matter at issue assume that they have seen no sufficient ground to warrant them in "modifying" their decision in the award of class 26 of the schedule. The official stipulation was for "one heaviest bunch of white Grapes," and the official award was made to the bunch which was beyond all doubt the heaviest when weighed by them. The competing bunches were weighed by the same officials, with the same scales, and at the same time, and one was found to weigh over 26 lbs. and the other under 26 lbs. The Judges had no other object than to do justice, and they awarded the prize to the heaviest bunch. Their decision was called in question, and the justice of it was disputed. But considering the case calmly and without bias—holding the balance perfectly evenly—we are bound to ask that if they had awarded the prize to the bunch which weighed under 26 lbs. instead of the one which weighed over 26 lbs., would their decision have received general approval? We think not. They would have been taunted on the standing

existed will be established, and none can regret that the matter has been fully ventilated. So long as the judging of a bunch of Grapes was left to individual interpretation, so long must suspicion lurk in many minds, but if once an accepted standard can be arrived at a great cause of doubt and dispute will be removed.

We submit the accompanying figures as illustrating what a bunch of Grapes should and should not be.

Fig. 84 is a cluster of fruit springing from two distinct axes, and constitutes undoubtedly two distinct bunches, and should be unhesitatingly disqualified when offered in competition as "a bunch of Grapes."

Fig. 85 is a cluster of fruit springing from the same eye,.

Fig. 84.

authority of weights and scales, and the wording of the schedule, in awarding the prize to the lightest bunch.

But then comes the objection that the bunch was not a bunch, or that it was more than a bunch. But to what authority could the Judges or anyone else turn? to what standard could they appeal? on what written law or definition could they base their authority in proof or disproof of the exhibit being legitimate? There was no law on the subject, and they made one on the spot. They could not turn to any recorded definition, so they relied on their own judgment and the decision of scales and weights.

There was not a written decision to guide them, simply because there had not been a necessity for such a record; yet, as the sequel has proved, there was an accepted reasonable standard which has now found utterance, and that utterance we shall attempt to define.

It is the unanimous opinion of men who are capable of comprehending a given subject that enables a standard to be arrived at which ought to be accepted and respected. We are in possession of authorities sufficient to define what, according to the professional and practical mind, is the standard for judging a bunch of Grapes. We submit that standard for future guidance—we submit it until something else expresses a better reflex of the horticultural mind as the condensed convictions of British Grape-growers.

In the controversy which may now fittingly close nothing has been expressed which should in any way mar the good feeling which should exist between competitors; but, on the contrary, if an accepted standard can be arrived at for judging "a bunch of Grapes," greater confidence than has previously

Fig. 85.

which in reality contains two axes of growth or bunch bases, and the cluster is a twin-bunch, and it cannot be legitimately regarded as "a single bunch of Grapes;" it must also be disqualified.

Fig. 86 is a true single bunch of Grapes as the distinct growth from a definable point of the axis, having a distinct

Fig. 86.

simple peduncle between the lateral and the shoulders, and afterwards dividing into shoulders and other branches. No matter how many branches it may afterwards assume, provided it breaks from the lateral with one simple peduncle, it is a legitimate single bunch of Grapes.

#### OSMASTON MANOR,

THE HEAT OF J. WRIGHT, ESQ.—No. 1.

"G." HAS been revelling in his researches amongst the antediluvians—those who were before the Flood, the flood of

antiquity. I was in the flood—the modern deluge, which submerged the country for miles, converting the roads into rivers and the fields into lakes, uprooting garden crops and washing away the fruit from the orchards. That is a portion of what I saw in my route through the midlands.

Ashbourne, at the foot of the Derbyshire hills, is the railway station for Osmaston. The rain on the day of my visit poured in torrents, and the streets were 8 feet deep in water, the people battling the flood with boards and clay to keep it out of their dwellings. After a watery journey of three miles and a half I reached my destination, and my readers may think of me as faintly illustrating the unenviable position of that familiar comparison a "drowned rat." I cannot bear personal testimony of the efficacy of Mr. Marshall Hall's system of restoring persons apparently drowned, but I can that of Mr. and Mrs. Booth, and I shall always think of the gardener's cottage at Osmaston as the hospitable Ararat of my watery midland tour.

Osmaston—its mansion, grounds, and scenery—is one of the finest of the Derbyshire demesnes, and is, perhaps, second only to the ducal seat of Chatsworth in extent, picturesque position, diversity of attractions, and good keeping. The mansion is of recent erection; it was commenced in 1846, and completed in about ten years by the late F. Wright, Esq., a gentleman who had a just claim to a trio of greatness—great wealth, great taste, and great benevolence. He was a patron of all that was good, a friend to all who needed the hand of friendship. In building his mansion he did not consider his own luxuries only, but he erected at the same time a church and, I think, a parsonage (one amongst many), also a village. The church at Osmaston is a massive and imposing structure, and the village is a model village. It is tenanted entirely by dependants on the estate, and the labourers are housed in semi-detached villas having good gardens and good—that is, low rents.

Mr. Wright left behind him an honoured name and qualities which are inherited by his sons. The present owner of Osmaston is the same kind master as his predecessor, and the same good landlord; he has the same disposition to improve his residence and grounds, and his admiration for and knowledge of trees and shrubs enables him to plant and project to good effect. Another son, whom I am honoured by knowing, has, in obedience to his benevolent nature, relinquished the quietude of a country parsonage and taken upon himself the more laborious duty of Honorary Secretary of the London Church Missionary Society, and thus devotes his means and ability to the public good. I name this as an instance of the power of example, the fruits of practical teaching.

For some years Mr. Booth had relinquished gardening; he had, however, a continual yearning for his old love, and this and another journal throughout these years were his cherished companions, keeping him abreast of gardening progress, and he started afresh, feeling no loss; and the state of the gardens at Osmaston at the present time afford sufficient testimony of his skill and the usefulness of the gardening press.

I will now glance at the place itself. The features which demand notice are the mansion, conservatory, aviary, gardens, rockery, and pleasure grounds.

First as to the MANSION. The engraving gives a very good view of this, but does not adequately show its size. It is a stone building of great solidity, and in appearance is plain, massive, and dignified. It has recently undergone considerable alterations. When the view was taken there were no chimneys, but all the smoke was taken away by the lofty shaft which is in the kitchen garden, and is seen on the left of the engraving. This shaft was a great work and ornamentally built, but the present owner, not liking its appearance, lowered it considerably. There was then not a sufficient "lift" for the smoke, and chimneys were erected on the mansion. The shaft is about 18 feet in diameter at the base. It is built on arches on a foundation of concrete 18 feet in depth. Beneath the arches are the boilers which heat the garden structures, and the shaft takes the smoke from the fires. It is ascended by a spiral staircase of cast iron, and the view from the top, in its now lowered state, is magnificent.

Beneath the mansion are cellars of no mean order. They are noteworthy as containing a railway for the conveyance of coals and other requirements. From these cellars to the different parts of the mansion are hydraulic lifts, so that everything can be conveyed into and from the different rooms with the greatest ease. Every room has, I believe, a connection with the cellars, and the lift will lift men as well as com-

modities. This statement will give an idea of the size and elaborate finish of this fine mansion. I come now to the

CONSERVATORY.—This is connected with the mansion by a museum and picture gallery, which is shown with the supporting arcades in our engraving. These arcades are now covered with Roses, Clematis, and other ornamental climbing plants. The picture gallery is on a level with the gallery which encircles the conservatory, and affords a lengthy and beautiful promenade. From the basement of the structure is also a spiral staircase leading to the gallery above.

The conservatory is a noble structure, lofty, and with a semicircular roof. It has a central promenade and two side walks. In the centre is a fountain surrounded by fine standard Orange trees in perfect health and sprinkled with fruit. The two beds on either side the central walk are planted with Camellias, Palms, Tree Ferns, &c., and are further ornamented with Agaves and other appropriate fine-foliaged plants. Flowering plants are also interspersed in considerable numbers. Azaleas are well and extensively cultivated, and all the usual decorative plants are grown and forced on a large scale. Solanums are much relied on for their bright-coloured fruits, Wetherill's hybrids being found the most effective of the scarlet-fruited section; and the Golden Gem of Messrs. Veitch and Sons being found by Mr. Booth to be the best of the yellow-fruited varieties. A thousand Hyacinths are forced annually, and other bulbs in proportion, and these, with the plants named and thousands which we cannot enumerate, create splendid displays during the winter and spring months. Camellias are also cultivated in pots, and with frequent top-dressings, copious waterings, and cleanliness are in fine health and condition.

I must not leave the conservatory without noticing the summary treatment to which a fine *Alsophila* has been subjected. It is well known that Tree Ferns will occasionally grow too tall for the structure in which they are planted. The specimen here was pressing against the roof, and its beauty was lost. Mr. Booth cut it down, took off about 6 feet from its stem, dug up the root, and planted the top as a cutting. Previous to putting in this gigantic cutting he denuded it of its fronds; he planted it firmly in good soil and kept it moist. Eventually the cutting pushed some abnormal growths, which were, however, followed by true fronds, and it is now a fine and well-rooted plant. The cutting was put-in in February of the present year, and was about 10 feet in length. It was a somewhat novel yet thoroughly successful experiment, and is worthy of record. In the conservatory was flowering a fine plant of *Hedychium Gardnerianum* which, Mr. Booth says, is admirably adapted for the subtropical garden: its light yellow flower spikes were very effective.

Adjoining the conservatory is a cool exotic fernery, the Ferns growing in niches in the walls, in baskets, and on rockwork. On the rockwork is planted that fine old variegated plant *Aspidistra lurida variegata*, which is in exceedingly good health and colour. I cannot dwell longer on this noble conservatory and its adjuncts, which was once heated by a mile of hot-water piping, but now the heating is improved by larger pipes and a better system of distributing their heat. Near to the conservatory is the

AVIARY.—I am not an ornithologist, but that is not necessary for the enjoyment of this beautiful enclosure. It is enclosed by massively built walls about 15 feet high, and has an arched wire roof. The centre of the ground has been excavated and formed into a rugged and precipitous dell. Bold rocks jut out at every conceivable angle and with delightful irregularity. Trickling streams form tiny rivulets and gather into a glassy pool at the bottom, where the Water Lily and kindred plants luxuriate. On the jutting rocks are alpine plants relieved by the rigid forms of Aloes and Yuccas. The banks of the dell are turfed and planted with shrubs, and near the water's edge the *Primula japonica* is exactly at home and throws up splendid whorls of flowers which cannot be approached by pot culture. This work has been recently done by Mr. Wright and his gardener, who are evidently adepts at this mode of ornamentation.

But besides the water, rocks, shrubs, and plants are "birds, birds everywhere." On the girders of the roof are long rows of brilliant plumage as bright as are the flowers below. In the nest niches of the walls they nestle, and the bushes are alive with their flustering gambols. There are birds of every colour; some rare and of great value, others more familiar, but all revelling in liberty, and their songs and their sportings bespeak them happy. This enclosure may be about 50 or

60 feet square. At the end is their feeding house, into which they pour at stated intervals through openings in the door. In the centre is their dining table, and the well-finished cases of drawers on one side are their larder; and on the other are, I suppose, their bedrooms—rows of separate cages, into which they retire at the proper time. Adjoining is the pigeonry and henery. The aviary and its connections at Osmaston demand more than this passing notice. For extent, cleanliness, and diversified attractions it is capable of affording enjoyment to all fancies and gratification to all tastes. I will now pass to a different and less ornate feature of Osmaston, and note briefly its

**GARDENS.**—I mean by these the kitchen, fruit, and forcing gardens. There are two walled gardens—one being devoted almost entirely to fruit culture, the other to vegetable-growing. There are also strips of ground outside the walls, making the amount devoted to culinary purposes about six acres. The

walls are very strongly built and finished with cast-iron copings which project about 6 inches. But I will first glance at the glass structures. These comprise eighteen houses. Six are devoted to the cultivation of Peaches and other fruits, four to Grapes, an equal number to plants, with erections for Cucumbers, Melons, and general forcing purposes.

My previous remarks have been of rather a glowing nature, but I must now draw a veil. If justice in some departments has demanded of me to write freely and approvingly, truth in another branch compels me to write soberly. Well, there are no Grapes at Osmaston. A fine garden like this without Grapes sounds like a misnomer, but the late owner of Osmaston appears to have thought more of plants than Grapes. He had a rich and valuable collection of plants, and the Vines appear to have been grown only, or principally, for affording shade to the specimen Orchids. These valuable plants have been sold, and in their stead the present owner is hoping to have Grapes.

Fig. 59.—OSMASTON MANOR—THE TERRACE FRONT.

New vineries have been erected, one 18 feet wide and 40 feet long for Black Hamburgs, another of the same dimensions for Muscat of Alexandria, and others of similar size for new varieties. The front walls are built on arches, and the borders are 16 feet in width. They are concreted, and have a sharp fall from the ridge in the centre where the Vines are planted. Drain pipes are laid at 4-foot distances, and are connected with an outfall or catch-water drain running parallel with but below the borders. The beds have 18 inches of drainage, and about 3 feet of soil, composed of good sound turf and a liberal admixture of bones. Provision is, therefore, abundant for taking water out of the borders, and it becomes consequently a primary question of pouring it in. Borders so constructed cannot easily have too much water given them; a fact to which Mr. Booth is fully alive, and he is provided accordingly, for he has only to turn a valve and he can flood them to repletion. It is just possible that more mistakes have been made in making Vine borders too dry than too wet, and it cannot be too well remembered that where a complete system of drainage is effected a proportionately full supply of water must be provided. This is the case here, and good Grapes are as certain to follow as night follows day. Fruit is already foreshadowed, for the Vines which were planted in April of the present year have made canes 22 feet in length after having been three

times stopped. The canes are stout, short-jointed, and well ripened, and will carry good Grapes next year.

The Vines are planted closely, every alternate one being intended to be borne heavily, and subsequently taken out, resting the permanent canes which are about 4 feet apart. Mr. Booth is, however, not quite comfortable as to leaving the dead roots of the nursing Vines in the border lest they should engender fungus, and he is almost inclined to preserve the whole of the Vines, cutting every alternate one down annually, and cropping them on the long-rod system. If he carries out that idea it is probable that he will obtain more and finer fruits than he would secure by any other means. Experience as to the effects of dead roots in Vine borders is needed. Very many growers have planted Vines thickly with the object of removing the surplus canes, and they now hesitate to carry out their object for fear of inducing fungus on the dead roots, and which may spread to those of the permanent Vines. Mr. Peach opines there is no fear of danger on this score, and his extensive travels and careful observation enable him to speak with authority; still, some records of actual practice would be opportune and acceptable. Mr. Booth does not intend to plant any more surplus Vines in his permanent borders, but would prefer to fruit them in pots or tubs, a practice which is recommendable for its safety. His Vine borders now are sur-

faced with manure, and in a short time Ormston will be able to produce Grapes worthy of itself.

Other features of this garden, including the rockery, I will notice in a future number.—J. W.

## NOTES ON VILLA AND SUBURBAN GARDENING.

The summer bedding season may now be considered over, for from the late frosts we have had, together with much wet, the plants have become so shabby that no dressing and cleaning, if ever so particularly done, will revive the general class of bedding plants sufficiently to compensate for the labour bestowed upon them. They should therefore be cleared away as soon as possible, and more especially if it is required to fill the beds with other plants for winter and spring decoration. Spring gardening is particularly suitable for small villa residences, where, generally speaking, all surroundings are of an ornamental character. Besides bulbs there is no lack of inexpensive plants suitable for the purpose. They may not flower at the first outset so satisfactorily, but then as spring weather improves the plants improve also, so that at the least one may calculate upon three months' good bloom in addition to that afforded by the usual summer bedding plants. Surely this is worth trying for; and again, for the beds to be clothed in winter with foliage even without flowers, are better to look upon than the bare earth. Let me name a few plants that should be tried. In the first place, however, the beds should be dug deeply and made level. No manure need be added now, but leave this to be put on at the summer digging.

*Sempervivum californicum*, a perfectly hardy plant, makes capital edgings for all beds, and the *Pyrethrum Golden Feather* is also a good edging plant. For this to stand the winter well the seed should be sown about the middle of July; the plants then produce good foliage by November, and stand the wet without becoming unsightly, as do those from seed sown in March. We have the *Violas* in three colours—blue, white, and yellow, which make either edgings or good showy beds of themselves. Another useful plant is the *Stachys lanata*, which is a dwarf grower with large silvery foliage; it is a good edging plant to either beds or borders. Wallflowers, too, ought to be planted freely. There are some excellent colours from seedlings sown in June which bloom in early spring, and what can be more enjoyable than the perfume of Wallflowers? If necessary the plants are to be had in distinct colours, as dark red and bright yellow. We have *Polyanthuses*, too, in almost endless variety of colours, and they are all sure and profuse bloomers, as are the double and single *Primroses*, which are great favourites, and for spring gardening hold a prominent position. *Golden Thyme*, too, must not be forgotten; it comes a beautiful bright colour in spring, but for summer bedding it loses its colour and becomes green. There are also the red and white *Daisies*, which can be had in any quantity, and will do well particularly in heavy soil. Forget-me-nots, both white and blue, must be included, as well as *Cheiranthus Marshalli*, a dwarf, yellow, dense-flowering plant, and one of the most useful plants for spring decoration. *Alyssum saxatile*, *Arabis alba*, and *Aubrietia grandiflora* are also deservedly admitted into this list.

*Eucnymus radians variegatus*, a dwarf plant with white and green foliage, and perfectly hardy and easy to propagate, is effective in the winter and spring garden; and the Silver-leaved Grass, *Doctylis glomerata elegantissima*, which is quite hardy, makes a good edging for both winter and summer decoration. Next should be mentioned *Phlox subulata* and *subulata alba*, which produce a mass of rose and pure white flowers, having also a dense mass of green foliage. All the plants mentioned in the above list will bear moving and transplanting well.

To the above list may be added several annuals raised from seed, either by sowing in September or later on in cold frames, and planted-out in spring. These consist of *Silene pendula* and *alba*, *Lasthenia californica*, and purple and white *Candy-tuft*. *Nemophilas* are, perhaps, not so safely to be trusted outdoors, as frequently too much wet destroys them, but on dry sandy soils they will withstand both frost and wet tolerably well. To make safe they should either be sown where they can be protected outdoors, or sown in boxes and placed in a frame to be readily put out in the spring. Then there is the *Saponaria calabrica*, one of the most lovely spring-flowering plants known; *Virginian Stock*, *Limonanthus Douglasii*, *Godetias*, *Viscaria*, *Collinsias*, *Calandrinias*, and many others of great beauty. They should be planted thickly, keeping a few in reserve of each sort to fill-up vacancies.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

It is now time to take up the usual root crops. Some sorts, such as Parsnips, are perhaps as well in the ground during winter; but when all the roots, such as Carrots, Parsnips, Beet,

Salsify, Scorzoneria, Turnips, &c., are stored together in a cellar or cool shed it is much more convenient, especially as they are frequently wanted in wet or frosty weather. A good plan is to pack them closely in sand, and all the above-named roots will keep well all through the winter. It is necessary to be very careful at the time of lifting the roots so as to prevent them being bruised; the Beet is quite spoiled if the tap roots are injured in lifting. The roots ought to be placed carefully in a barrow or baskets by hand, and lifted out and stored with the same care.

We take the opportunity of every fine day to earth-up the Celery. It is quite necessary that the leaves and soil be dry when this is done. It is also a good plan to earth-up from both sides of the rows or beds at the same time, for when one man is earthing-up from one side only at a time he sometimes pushes the plants to the opposite side, and this is very injurious. The soil should be placed to the plants carefully, and not be allowed to fall into the centres. A good plan is to tie the leaves lightly together with a strip of matting before earthing-up. Artichokes must now be covered up. The best protecting material are leaves and stable litter: this should be placed round the plants to the depth of a foot or 9 inches, bringing it up close to the leaves, but not so close as to cover the centre of the plants, which should be open. The object of covering is to protect from frost, and this thickness will effectually do so. Spent tan has been recommended as a protective agent for Artichokes, but we have not seen it used.

We have just been able to place the Cauliflower plants in the hand-glasses; it is about two weeks later than they are usually planted out. The remainder of the plants that are not required for the handlights have been pricked-out in boxes; the plants are not over-large, and if sharp frosts do not set in there is nothing lost by late planting. When the plants are strong and are put out early many of the strongest are apt to button: this is not the case with the late plants. Those who planted out their plants two or three weeks ago must pay attention to them during this dull wet weather. All the air possible must be admitted, the soil between the plants be lightly forked over with a pointed stick, and all decaying leaves to be removed. Lettuce plants in frames should also be aired as freely as possible, the soil to be pricked over, and the plants be treated as advised for Cauliflowers.

### PINE HOUSES.

At this period of the year the old growers used to turn over their tan beds, adding either fresh tan or leaves to maintain a bottom heat for the winter; but they generally overdid it. The beds were deep, containing a great body of tan or oak leaves, and either of these when in quantity retained the heat for months. The result used to be that all the active rootlets perished during the winter months from the high temperature at which the roots were kept. At present the fruiting Pines—those intended to be started about the 1st of January—are kept in a temperature of 60° at night. During cold weather the minimum may be 55°. There is very little root action at this period, and about 75° or 80° is as high as the temperature of the bed ought to be; and as the plants are comparatively dry at the roots they will not throw up fruit until the house is started. There is nothing to be gained by unduly exciting suckers and succession Pines at this season. The suckers planted out or potted in August are now well rooted; but they are allowed to rest at present, and will not be hurried until February, when a good watering will be given them. The beds are turned over, and when the plants are fairly started they are potted into their fruiting pots. In the fruiting house there are a number of fruits swelling, and some of them are yet in the early stages only. With these it is necessary to keep the temperature up to 65°, or in mild weather to 70° as a minimum, taking advantage of sun heat to run it up to 85° or more. Fruit that is now ripe or ripening will keep best if it is cut just before it ripens and is removed to a cool room, and it seems to keep in good preservation longest if the room is rather close and dark.

### CUCUMBER HOUSE.

The most difficult period for obtaining Cucumbers is now drawing very near; but if the plants that were put out about the first week in September have not been cropped at all, or at least but very lightly, they will now come into bearing; but a succession of Cucumbers will not be obtained if the plants are not well treated. In the first place, the house must be light and in a position to receive the full benefit of the sun. It must also be well ventilated, for if fresh air is not judiciously admitted daily the plants will soon show the effects of impure air—the leaves will be wanting in substance, and the growths be too weak to produce fruit. In fine weather both front and top ventilators should be open at the same time for a few hours in the middle of the day. The night temperature should be 65°, with a proportionate rise in the daytime. Good substantial loam, to which has been added a fourth part of rotted stable manure, is a capital compost in which to grow the plants. A foot in depth of this is quite sufficient if it is placed over the drainage, and a temperature of 80° or 85° kept up in the bed

from hot-water pipes underneath. Many gardeners fancy a light compost is preferable for Cucumbers, and use large quantities of leaf mould or peat in the soil. But no one could grow better Cucumbers than Mr. Monro of Potter's Bar, his new variety Duke of Edinburgh having been repeatedly admired at the meetings at South Kensington during the winter months. The compost he uses to produce such excellent results is stiff clayey loam from the bottom of a pond. His success seems to arise from keeping up a high temperature—70° at night; and this, which would be thought much too high by some, does not injure the constitution of the plants.

#### PLANT STOVE AND ORCHID HOUSES.

It is now a good time when work is not pressing to look over any plants that may be infested with bug or scale. There is no better way to destroy either of these pests than to use rather warm moderately strong soapy water, and washing carefully by hand, using a soft sponge. Such work must be done very carefully. It is better to clean only one plant thoroughly than to run over half a dozen and leave the axils of leaves and branches full of larvae. The same plants ought to be looked over a week hence, and any bug or scale that may have been missed at the first washing can be removed. As the growth of most plants, Orchids included, have by this time become matured, it is not so dangerous to fumigate. This may be done cautiously as a deterrent to thrips and aphids of sorts. Thrips are the most difficult to destroy; but they cannot do much mischief if fumigation is persisted in.

At this season flowering plants are not very plentiful, and the facility with which Palms, Dracenas, Crotons, and other high-coloured foliage plants can be grown, and which last so very much longer in beauty than flowering plants, causes gardeners to be rather careless in the culture of those plants which last in perfection for a very short time only. Still no plant stove should be without flowering plants at any season; and they are now especially valuable when the "cheerless night of desolation reigns supreme" out of doors. *Aphelandra aurantiaca* and the variety *Roezlii* are exceedingly useful at this season. *Eucharis amazonica*, though it is now very common, cannot be dispensed with. It is now in full flower with us; the flowers are in great abundance, even more so than usual. The reason of this may be that the plants have taken a very long rest since they last flowered. The plants had been kept in a cooler house, and we were enabled to keep them much drier at the roots. Then what a beautiful contrast to the brilliant-coloured and pure white flowers are the handsome clusters of the mauve-coloured bracts of the *Bougainvillea glabra*. This is now in full beauty, and when the flowering period is over it will be removed to the greenhouse to rest, preparatory to a fresh start in March next year. *Allamanda Schottii* is also very nicely in flower. The plant has been encouraged to make a quantity of young wood since August, and the young growths are flowering freely. *Ixoras* can also be had very finely in flower at this season, or indeed at any time. The trusses of flowers are formed shortly after the growth is made, and if the minimum temperature is kept up at 65°, with a little bottom heat for the plants, the flowers are perfected even at midwinter. Other flowering plants may be named which may be induced to flower at this time, even if this is not the usual time for their flowering.

Amongst Orchids the *Calanthes* are now in flower, and these beautiful plants are so easily grown that no collection of stove plants should be without them. The most useful plants for us are those that are grown in small pots. Three bulbs are planted in 5-inch pots, the staple material being rich turfy loam, a little rotted manure and sand is added. We have pots this year in which the bulbs produced almost, if not quite, weigh as much as the compost in which they are grown. During the growing season they require plenty of water, but after flowering no more water is required until the bulbs start into growth late in February or early in March, when they are shaken out of the pots and repotted. Some persons pot a score or more bulbs in large pans, which is a matter of taste, or as better meeting the requirements of the owner.

*Dendrobium nobile* has been placed in heat, so that the plants may be in flower about Christmas. This useful and easily grown Orchid will succeed either in a high or low temperature; but being a native of China it does not require the heat of an East India house, and during the winter a temperature of 55° is sufficiently high. Those plants that are being kept back for late flowering are placed in the greenhouse, and they do not receive any water unless the growths show signs of shrivelling, when water is applied to prevent this. *Dendrobiums* such as *D. Farmeri*, *D. densiflorum*, *D. thyrsiflorum*, and others of this section having made their growth in the East India house, are now removed to a house where the minimum temperature ranges from 50° to 55°. These are also kept as dry at the roots as possible without allowing the growths to shrink in the least. In all houses where a high night temperature is kept up it is quite necessary to sprinkle water on the stages and paths to obtain atmospheric moisture; but it is not desirable to syringe

the plants after this unless an isolated specimen should become infested with red spider, when the plant should be laid on its side and thoroughly syringed. Let air be admitted daily and freely on all favourable occasions. Many of the best Orchid growers admit air night and day both in the summer and winter months.—J. DOUGLAS.

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

JERSEY (Chrysanthemums).—November 10th. Major Howell, Spring Grove, St. Lawrence, Hon. Sec.

LOUGHBOROUGH.—November 16th and 16th. Mr. W. Pallett, 55, Baxtergate, Sec.

NORTHAMPTON (Chrysanthemums).—November 16th and 17th. Mr. N. Gutteridge, 61, Denmark Road Sec.

#### TRADE CATALOGUES RECEIVED.

Ewing & Co., Eaton and Cringleford, Norwich.—*Catalogue of Roses and General Nursery Catalogue.*

Ch. Huber & Cie. à Hyères (var) France.—*General Autumn and Spring Catalogue of Seeds and Plants.*

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

POTTING SOIL (T. C.).—The mixture of cow dung and cement, which is now crumbly, would do for mixing with other materials to form a potting compost for plants not objecting to calcareous matter.

FRUIT TREES IN POTS (T. H. C.).—Pearson's "Hints on Orchard Houses" will aid you. You can have it free by post if you enclose nineteen postage stamps.

KITCHEN GARDEN PATHS (E. B.).—If made of the following composition they are always dry and free from weeds:—Take two parts of very dry lime rubbish, and one part coal ashes, also very dry, and both sifted fine. In a dry place, on a dry day, mix them, and leave a hole in the middle of the heap as bricklayers do when making mortar. Into this pour boiling hot coal tar, mix, and when as stiff as mortar put it 8 inches thick where the walk is to be. The ground should be dry and beaten smooth. Sprinkle over it coarse sand. When cold pass a light roller over it, and in a few days the walk will be solid and waterproof.

SCARLET PRIMULAS (A. L. M.).—The flowers are bright and good, but they should have been packed in damp moss to preserve them unwithered.

FRUITS FOR HOT SOUTH WALL (C. W. F.).—You cannot have more worthy fruits than Peaches, Nectarines, and Apricots.

PEARS (T. M., Sarbiton).—They must have been very dissimilar for us to conclude they were six varieties. Are not more than one variety grafted on the stock? Send us other specimens, and put a note with them to recall our attention.

BACK NUMBERS (E. Webb).—If you enclose twenty-one postage stamps, restate the numbers you need, and send your address, they will be posted to you.

JERSEY HORTICULTURAL SOCIETY'S RULE.—"Audi Alteram Partem" informs us that the rule 8 only applies to plants grown in pots, and he encloses a printed form which Mr. D. De Faye signed; that form has this clause:—"I hereby certify that all the objects above described (fruits) and contained on the other side are of my growth." This disqualifies Mr. De Faye's specimens.

MEALY BUG ON CAMELLIAS (B.).—The spray sent is slightly infested with both mealy bug and white scale. Dissolve 8 oz. of soft soap in a gallon of water, and brush the solution carefully round the buds with a hard tooth-brush, using also a pointed stick to loosen the scale. The solution should be used at a temperature of 100°.

OVAL BED (Ignoramus).—Mark out two circles to form the ends of the oval of the size you need; then fix on one side a peg exactly opposite the middle of the space between the two circles, and at such a distance as that with a piece of string fixed to the peg and a nail at the other end of the string you can mark the side of the oval. Then move the peg to the same position on the opposite side, and with the same length of string mark the other side of the oval.

GOOSEBERRIES.—"If Mr. W. Taylor, Longleaf, will grow White Warrington Gooseberries, he will find them exactly the same in everything but colour as the old Red Warrington.—Yours truly, J. MACKENZIE, M.D."

PEAR LEAVES BRONZE-COLOURED (S. F.).—The roots have descended into the cold clay subsoil, and do not supply sufficient sap either to the leaves or fruit, consequently the leaves are discoloured and the fruit cracks. The descending roots must be cut away, some of the clay subsoil burned and mixed with the soil of the surface, a little well-decayed manure added, and the surface kept mulched to induce the roots to remain there.

HOSE-IN-HOSE POLYANTHUS (Old-fashioned Folks).—You are not old-fashioned gardeners, or you would know that the "Hose-in-Hose" is one

growing from the centre of another, and is one of the very oldest of the Polyanthus varieties.

**BEDDING DELPHINIUM.**—"M. H." says "I have used the common blue Larkspur Delphinium consolida as a bedding plant. With care and pegging-down it proves a very effectual plant to those of limited means."

**BUYING GARRISON (C. Princep).**—You are quite right in recommending the carcasses of animals to be sold, and less offensive manures to be purchased. Reducing them by decomposition, sulphuric acid, &c., is a process very few amateurs or gardeners would endorse.

**VINE LEAVES BECOMING YELLOW PREMATURELY (J. A.).**—The Vine seems to have received a check in some way. You fancy the roots cannot get into an outside border; if so, perhaps the fault is to be found in insufficient root action. You should examine the roots; the leaves sent are not diseased.

**FRUIT TREES FOR POULTRY RUN (Subscriber).**—The wall will not practically be of use, as from the standard trees you propose planting it would be shaded by them to an extent that no satisfactory results could be expected; and the fowls, were you to plant the trees so as not to shade the wall, would peck at the fruit they would produce fully half the height of a 6-foot wall, and the wall facing north is not suitable for the better kinds, but is only available for Morillo Cherries. We should have two rows of trees lengthwise of the plot, 15 feet from each side and 80 feet between the rows, and plant in the rows 30 feet apart, which will give a dozen trees, and these may be—*Pears*: Jargonelle, Marie Louise, and Bourré Dial. *Plums*: Oullins Golden Gage, Prince Englebert, and Victoria, with Onatser or Crittenden Damsen. *Apples*: Blenheim Orange, Dutch Mignonne, Lady Henniker, Cox's Pomona, and Tower of Glamis. If you level the ground at all trench it and throw it level as the work proceeds, and manure on the surface, sowing with grass seed in April.

**KITCHEN GARDEN ARRANGEMENTS (Idem).**—It will answer as you propose, but the fruit trees must not be on the side of the wall next the wall, but on the opposite one, and about 3 feet from it. Pyramid or espalier Pears and Apples would succeed admirably on the dwarfing stock, and the wall could be utilised for fruit trees. The Asparagus is quite old enough for transplanting. It may be moved now or in March.

**STORING PEARS, APPLES, AND POTATOES (Idem).**—The cellar will be suitable, only the pipes would probably give out too much heat, the fruit ripening too quickly, and the Potatoes being started into growth prematurely; but this you may obviate by enclosing the pipes in brickwork, with iron sliding ventilators to let out or confine the heat as may be required. The cooler the room, provided that frost be excluded, the better. Shelves of planed deal laths with spaces of about an inch between each will answer perfectly.

**HEATING SMALL GREENHOUSE (J. E.).**—You will see in our advertising columns an apparatus or stove which consumes oil, and it may be suitable for your purpose, but with hot water in a sufficient quantity of piping we do not see the necessity of an auxiliary.

**POTTING LILIUM AURATUM TO FLOWER IN AUGUST (Idem).**—Pot it 6 bulbs now, and keep the soil in a rather dry state through the winter and from frost. In spring place outdoors with the pots plunged to the rim in a sheltered position, and they will flower at the time you require, removing under glass if they are too backward, which we hardly think they will.

**POTTING GERANIUM AND PELARGONIUM CUTTINGS (R. H. T.).**—We can only account for the cuttings going off from being kept too moist. The plants require to be lifted carefully, preserving the roots with some soil adhering, and pot singly in 8-inch pots in moderately moist soil, watering sparingly until fresh growth is made, by which you may know the plants are rooting freely.

**VINES INFESTED WITH MEALY BUG (Mealy Bug).**—You must thoroughly cleanse the house as well as the Vines. The woodwork ought to be thoroughly cleaned with a brush and soft soap and water, the walls whitewashed, and the glass washed with clear water; but preparatory to this we should syringe every part of the house with the ammoniacal liquor of the gasworks diluted with six times its volume of water, and after having stripped the Vines of all the loose bark dress them with a composition formed of very finely powdered thoroughly-dried clay with an equal quantity by measure of gas or coal tar, and bring it into a proper consistency for using with a brush by adding eight times the quantity of the tar and clay combined of water at a temperature of 140°, so that to make nine quarts of composition you will require a pint each of powdered clay and gas tar, with a gallon of soft water. Apply with a brush, reaching every angle, crack, or crevice, taking care not to injure the eyes. It would be well to finish with twice painting the woodwork, and not being sparing of turpentine, which with the house closed afterwards will from its volatility fill the house, and which no existing bug can breathe and live. The border inside we should make quite yellow by sprinkling over it guano, and top-dress with clear compost. Nothing is better for syringing the Vines after starting than clear rain water, and if you continue this until the Grapes change colour the bug will not make such headway during the ripening as to cause any damage to the Grapes. We also recommend sprinkling the border over with guano and wash-in with water about every fortnight. It is beneficial to the Vines and good against mealy bug. The house must be clear of plants during the cleansing.

**SOLUTION FOR PLANTS INFESTED WITH MEALY BUG (Idem).**—Make a solution of soft soap 1 lb. to a gallon of water, and add a wineglassful of spirits of turpentine, and apply at a temperature of 120° with a brush to the stems, and to the leaves with a sponge. It must be used upon plants with smooth leaves only, as Crotons, Dracenas, Stephanotis, and Gardenias; and not those with soft hairy leaves, as Conocliniums, Thyracanthus, and Ferns. Mix the solution thoroughly.

**TREATMENT OF MARSHAL NIEL ROSE IN GREENHOUSE (A Constant Reader).**—The shoots being now the length you desire them you should stop them, and induce the ripening of the wood by keeping rather dry at the roots. The temperature of 45°, if from fire heat, is too high, as it will induce the plant to continue in growth, but that you may check by keeping dry. Do not prune more than to remove any soft unripe wood, and from every eye of the firm ripe wood you may calculate upon having a flowering shoot. The temperature is not, however, too high for Chinese Primroses (*Primula sinensis*). The flower stems as they rise should be removed until Christmas, as you require the plants to flower in March. Keep the plants near the glass, and carefully watered, encouraging after Christmas with freer watering, and giving weak liquid manure at every alternate watering.

**CREEPER FOR NORTH WALL (F. J.).**—The Virginian and Veitch's Creeper (*Ampelopsis Veitchii*) would answer, and are handsome, especially in autumn. The finest species, however, for a north wall are the *lyvia*, and for a wall of the height of 9 to 10 feet we should plant the smaller-leaved kinds, as *Hedera Donnelliana* and *H. taurica* of the green-leaved, and *H. elegantissima* and

*H. tricolor* of the variegated sorts, the green and variegated-leaved kinds together having a pretty effect.

**GRAFTING APPLES ON PEAR STOCKS (Idem).**—It has been done, but the grafts only lived a short time, and the practice is not therefore desirable. The trees so grafted never, that we know, lived long enough to produce fruit. Graft the stocks with Pears if you wish to change the kinds.

**PLANTS NOT THRIVING IN CONSERVATORY (J. R. S.).**—The shading with perforated zinc is sufficient to account for the plants doing so indifferently; and though it might not make the house too gloomy when the Camellias were making fresh growth, they, from being placed outdoors after the growth was made and the buds set in a vinery, would, unless hardened-off, receive such a check as to cause the buds to fall now, the check being given at an earlier stage. There is no need to remove Camellias from a conservatory at any time, and since we abandoned placing them in heat to make growth and form buds, with the resting outdoors, we have not had a noticeable dropping of buds. The chilling consequent upon the changing of plants from various positions cannot act otherwise than prejudicially, as shown by the casting of their flower buds. The consumption of gas in the house on party nights will not do the plants any good, but if only practised occasionally, and for a short period each time, would not materially injure them, but it is an evil, and often highly prejudicial from an escape of gas, and would be better replaced by oil lamps. In the green paint we see no occasion to look for injury to the plants, as after it is thoroughly dry there could not be given out any injurious vapour. The shading and gas, in our opinion, are the sources of the evils. A shading of tiffany inside put up early in April and removed at the close of September would give you all the shade required; and if there is an objection to the tiffany shading, brush the inside of the glass with a wash of whiting brought to the consistency of limewash by adding skim milk. It may be washed off at any time, or renewed if necessary.

**GRAPEES FOR LATE VINERY (W. G. C.).**—Either you must decide upon the late kinds, or those which are classed as late, and which will hang in good condition to Christmas. There is, however, generally such a glut of Grapes in autumn from not keeping and other circumstances, that we do not advise growing kinds that will not keep until March or later. Kinds of this description are Alicante, Lady Downe's Seedling, and Mrs. Pince, with Gros Guillaume, which, however, is a shy bearer in most places on its own roots, but on the Muscat of Alexandria stock it is found to do better, and is one of the finest of late Grapes. Those we recommend, but they would not succeed upon the Black Hamburg stock, and we should root them all out and plant with the late kinds. Madresfield Court is fine in the autumn, but does not hang long, and Black Muscat colours so badly as always to stand at a disadvantage with well-coloured kinds as Alicante and Lady Downe's.

**GREENHOUSE GRAPEES SHOWN AS OUTDOOR GRAPEES.**—"A person exhibits Grapes grown in a greenhouse as outdoor Grapes, and tries to satisfy the Committee that they are grown out of doors as the lights have been open for some time. How should the Committee act in such a case?" Refuse to allow them to compete as outdoor Grapes, or if a prize has been awarded refuse to pay it.

**NAMES OF FRUITS (J. Green).**—The large one is *Mère de Ménage*, the other we do not know. (*Connaught Subscriber*).—*Pears*: 1, Gansell's Bergamot; the others are not known. *Apple*: 2, Golden Basset. (*John Jeffries & Sons*).—1, Summer Strawberry; 2, Adams' Pearmain. (*A. H. M.*).—Nectarine Pear. (*Onward*).—We do not know the Apple. (*Mrs. J. C. Edwards*).—*Pears*: 1, Fondante du Comice; 2, Duncrore; 3, Marie Louise. *Apples*: 1, Scarlet Nonpareil; 2, Braddick's Nonpareil; 3, Farry's Pearmain. (*W. G. C.*).—*Pears*: 1, Bourré Bance; 2, Ne Plus Meuris. The Apples are not known. (*Beest Hill*).—A, quite rotten; B, Thompson's; C, Kerry Pippin; D, Collini; E, not known. (*Somerset*).—1, Doyenné d'Alençon; 2, Verulam; 3, Easter Bourré; 4, Winter Nellis; 5, Bourré d'Arenberg; 6, Broomepark. (*Stuart and Meiss*).—17, Collini; 24, Damsel's Seedling; 4, Norfolk Seedling; 11, Hawthornden; 2, Manx Codlin; 5, Yorkshire Greening. (*A Subscriber, Fife*).—*Grapes*: 1, Black Alicante; 2, Morocco Prince. (*J. Chappell, Hull*).—Both are Emperor Alexander. The larger one marked No. 2 may be Grand Duke Constantine, which is very similar to Emperor Alexander, but considerably later in ripening, and keeps longer. (*G. T. Hall*).—1, Verulam; 2 and 3, undoubtedly Scarlet Nonpareil; 4, not Duke of Devonshire, not known; 5, Golden Basset; 6, Lewis's Incomparable. (*Lyndhurst*).—1, Blenheim Pippin; 2, Franklin's Golden Pippin; 3, Cooke Pippin; 4, Court Pendu Plat; 5, Reineette du Canada.

**NAMES OF PLANTS (S.).**—Specimen too immature to name. It looks like a seedling form of the common Male Fern, *Lastrea Filix-mas*. (*V. B. Down*).—The "plant" is *Sedum Sieboldi*. The Ferns are without numbers. (*G. S.*).—1, perhaps *Aster multiflorus*; 2, a *Lyperis*, probably *L. crassicaulis*. (*A Subscriber*).—1, *Centaurea montana*; 2, *Clematis Flammula*; 3, an *Anemone*, but we cannot determine the species from the insufficient material sent. (*S. B. and J. B. S.*).—We cannot identify plants by their leaves.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LES BASSES-COURS DE L'ANGLETERRE.

#### CHAPTER V.—BASCHURCH.

THE poultry establishment at Little Ness has only just attained full swing, for Mr. Darby had to leave Bridgnorth and pitch his camp at Baschurch after rather short notice, consequently when he came the runs were not ready, the houses were not built, and nothing was in working order. This threw him back a good deal last season; but now the warm corners have been found, and the sheltered runs discovered, and the establishment is in full operation once more. Even now Mr. Darby has much to make way against, for the place is exposed, and cold winds blow over it. The soil, too, does not seem over-advantageous for rearing chickens, the birds taking a long time to mature and to moult in the autumn, and the country round teems with foxes, which have made several inroads and carried off valuable birds.

Little Ness is famous for prize-bred live stock of all kinds, for on entering the yard we find a pack of useful fox terriers of the

most approved strains, living in a set of substantial kennels; and there are, too, "Royal" winners in the stable, and silver-cup foals in the fields, and highly-bred cattle of all kinds in the stalls, while a first-prize Crystal Palace cat is found in the harness-room. But we must turn to the poultry yards.

The farmyard here is what a farmyard should be—long rows of shedding for feeding cattle, barns and granaries of huge dimensions, and such stacks! No little round dumping affairs, or brick-loaf-looking erections, but rows of stacks like miniature mountains, covering we dare not venture to say how much space, and all raised up on iron stands; consequently the dry runs under them are quite grand, and chickens should really do wonders. But it was October when we were there, and we found this fine farmyard given up to a miscellaneous collection of birds, consisting principally of Buff Cochins, Spanish, and Dorking hens. These birds should moult out well here and come in useful, for they had everything in their favour.

Coming from this stackyard we pass through a little gate and enter the poultry field where the long row of runs are. We can safely say we never saw such a grand row of poultry pens. They were built regardless of cost, and we will try to describe them. They comprise twelve or fourteen houses, built in one long row. The whole range is thatched, the roof being very deep and thick, which keeps the temperature perfect. Each house is about 16 feet square, and is fitted with a large dust bath and all necessary poultry furniture. Each house has a huge run laid down in grass and planted with shrubs. The pens are boarded up to about 4 feet, and then have 6 feet of wire netting, while there is at the bottom of each yard a small door to let the inmates of the pen into the field at any time. Iron guttering runs along the whole roof, and each door has spring hinges, in fact it is the most complete range of houses we ever saw. It is impossible to give any fair conception of them on paper.

But to pass to the inmates. In No. 1 we found half a dozen Buff cocks moulting well, one or two especially of great promise. In the next we found a lot of Silkies, many of them perfect and fit to win. In the third was a grand old coloured Dorking hero coming on well in his solitary retirement. In the next was a fine White-crested Poland cock also doing well. In the fifth were half a dozen Black Cochins, one of which while we were there was sent off to Edenbridge Show, and brought home the first-prize card. In the next were Cochins, and here we paused some time, for many of them were of great merit. Two Buffs and a White were immensely taken with, and shall expect to hear of their doing great things. In the seventh pen was a beautiful old Spanish cock, good in face and promising well. In the next were White-Crested Poland chickens, one of them the grand pullet that so much has been said about. We found adult Polish in the next, and so on throughout the whole range, while Pigeons flew about everywhere, and built their nests in any of the houses at pleasure.

From this field we passed on to a very pretty spot. It was to our mind the nicest of the runs, for it was sheltered on all sides, and had a little pool of water close to it. The grass here was kept short and well rolled, for it was, as well, the lawn tennis ground. Here were the Cochins cockerels, and a very good lot they were. Among them we saw the Aylesbury and Oswestry winning Buffs and the Blacks which won at Aylesbury, Edenbridge, Alexandra Palace, &c. The Palace cup cockerel was one of the best Blacks we ever saw, and we prophesy a good career for him. All the birds were in beautiful condition and in perfect bloom.

We had now seen all the birds which were up at Little Ness, and walked on to Vale Wood, a charming spot about a mile off, covered with fine oaks and beeches, under which grass and ferns grew in wild luxuriance. On our way we passed a paddock with a big poultry house in a corner, and here were cockerels of all ages—Dorkings, Cochins, and Spaniards—all living together in perfect harmony, and many of them very promising; in fact, we believe since we saw them one or two have come to the front in the prize lists.

It is at Vale Wood that the foxes trouble Mr. Darby so much, but we found here a most ingenious contrivance of Martin's the manager: a space 100 yards square had been cleared round the poultry houses, in each corner a strong post had been sunk into the ground, and a stout wire strained from post to post. In each corner was a dog kennel, and each dog had a chain which was fastened to the wire by a ring. By this means each dog had to guard 100 yards, and he could run up and down this space at pleasure, so keeping off all intruders, whether two-legged or four-legged, from this square which contained the houses and roosting sheds.

We found here Coloured Dorking hens, rose-combed and single—great-bodied birds, and most of them well through the moult. We were shown many a champion here, and very grand they looked. Here, too, were troops of Game Bantams, a grand rose-combed Dorking cock, some splendid White Dorking hens, a good Coloured Dorking pullet or two, besides a miscellaneous collection of young growing stock which had nothing to do but

to grow, basking lazily in the thick bracken, and picking about under those fine forest trees.

Opposite the manager's house was a little paddock with a nice thatched shed in the corner. Here were the Cochins pullets—Buffs, Blacks, and Whites. The former were very good, two or three of them being in colour equal to any we have seen this season, and we since have learned that one of them was the pullet so much admired at the Aston Park Show. These pullets, especially the Buffs and Blacks, must come to the front sooner or later.

As we walked back we passed some cottages where a nice Game cock or two were out at walk, and when we once more reached Little Ness we went to the poultry room, where in small straw-littered pens we found various old cocks in process of changing their summer clothing. We took a great fancy to a Black cock, and a White bird was coming out a good colour, and will make a winner we should think. We only had to see the Spanish now, and then we had finished the whole yard. These we found in a large covered-in manure-yard, and a capital collection they seemed to be, nearly fifty of them, hens, pullets, and cockerels. We thought the place warm and singularly adapted for bringing out their faces and developing their combs.

This, then, was the Baschurch establishment. We have had to go over it rapidly, as it is large and the number of birds great; but we have given, we hope, some idea of the place, and leave it wishing Mr. Darby every success, for he is a genuine fancier and an honest one, and well deserves every card his birds bring home.—W.

### ALEXANDRA PALACE POULTRY SHOW.

YOUR contributor says that Mr. Billett had the birds speedily packed at the close of the Show. We are at a loss to know whence the information was derived, for Mr. Billett had nothing whatever to do with repacking the birds, which was done by the Secretaries and a numerous staff of assistants; and with about a dozen exceptions every bird was in the hands of the railway people before four o'clock on Friday morning. We may add that Mr. Billett executed his contract for the pens in an eminently satisfactory manner.

The next misstatement in your report is that the birds while at the Show were fed by the Messrs. Spratt & Co. On the contrary, the birds were fed and attended to during the Show by Mr. H. Brown and several feeders; and with the exception of two or three cwt. of Spratt's meal the whole of the food stuff was supplied by Mr. R. Pratt.

We cannot help remarking also that in the report on the Pigeon Show your reporter should have altogether ignored such important varieties as Carriers, Pouters, and Dragons, which all had large and well-filled classes, and we think were deserving of some notice.—W. J. NICHOLS, P. H. JONES, *Secs.*

[The only reason that no comments on the Carriers, Pouters, and Dragons were published is, that the report on them was confided to a gentleman who did not send his notes.—EDS.]

### MALAYS.

IN your report of Alexandra Palace Show I see you have favoured the Malay fancy with fuller notes on this class than is generally the case with other papers that devote space for poultry matters. I am led to believe, like more of the fancy, that Malays are a breed which few know how to describe, not knowing their true character. You specially name the Green colour, as if they ought to be either White or Pile. Now as there is no standard colour for Malay hens, I maintain that colour should not have too much weight, but style and size, and the neck or hackle coat of feathers, with plenty of lag.—R. HAWKINS, *Seaham.*

### THE FRENCH CLASSES.

IT shows the increasing popularity of these breeds, especially of the Houdans, that in a season so confessedly bad for chickens such birds could have been brought together as at the Alexandra Palace Show; and those who like myself have watched the progress of the breeders must admire the energy and intelligence by which they have effected so vast an improvement—an improvement which would, I believe, make our neighbours open their eyes as wide as did the rose-growers when they saw the magnificent pot roses at the Great International Exhibition. Not merely the size, but the quality of the birds was wonderful. But must not some people give great latitude to the interpretation of chickens? I saw pullets with scaly legs, and in all my breeding experience I have never met with that in birds under twelve months.

Of the four classes I think the Houdan cockerels were the weakest in point of quality, and there was hardly a bird in it with which some fault might not be found. The cup bird, which belonged to my friend Mr. Dring, was a very large fine bird, good in colour, but with too scanty a crest; legs light in colour,

but the comb was not what is now recognised as the true Houdan comb as distinguished from the Crève. Second-prize bird was worthy of the position he took; but he had a fine crest, and legs were very light. 627 a fine bird, but he had too small a comb and wattles to suit my ideas of a thoroughly good bird. 626 a good bird, but too dark. 630 would have been a fine bird but for his having a squirrel tail, which made him look as if the sickle feathers had been pulled out and stuck in again. 610 a good bird. 617 a large bird, very dark, bad shape, and with an exaggerated leaf comb. 618 good, but too small.

The pullets were a very fine class, and when one looks at the prize list and sees that out of thirty-four entries nineteen, or more than one-half, were noticed, it is evident the Judges thought so too. The first-prize bird (651) did Mr. Wood great credit; she had a very fine crest, was good in colour and shape—quite a model of what a Houdan ought to be. The second (635, Mr. Dring) was a very fine bird; in fact, he had four there altogether which were excellent, and I am not sure but I should have preferred the highly commended bird (684) to that which obtained second. The third was good, and so was 553, fourth prize (Mr. Quibell). Amongst the highly commended birds I like 642 (Mr. Hibbert) quite as well as some of those which obtained prizes; but I can quite understand the difficulties the Judges must have experienced, and I thought to myself how very little I should have cared to have judged such a class.

The Crève-Cœurs were remarkable not less for their excellence, but also for the manner in which, in racing parlance, the favourites were nowhere, and outsiders came to the front. Messrs. Dring, Outlack, Crabtree, Wood, and Ewbank were distinguished by such new exhibitors as the Rev. J. G. B. Knight, Mr. Upsher, and Mr. D. Faye, and unquestionably their birds were very fine. The first and second-prize cockerels were grand birds, brilliant in colour, rich glossy black, rather too upright in comb. 676, third prize (Mr. Malden), was a fine bird, but lacking the brilliancy of colour of the first and second. 685 (Mr. Dring) was a good bird—true Crève-looking bird, and I could quite imagine his owner thinking he could not be beaten before he brought him up.

Pullets were a splendid lot, the first-and-cup bird in all respects first-rate. The second, a Jersey bird, was very nearly equal to it, and the size was something wonderful. I liked 696 (Mr. Dring) very much, a well-shaped fine-coloured bird. Mr. Knight, who showed cockerels so well, was nowhere in pullets, only coming in for commendation for 685. 686 was curious, a perfect White Crève, but I should hardly think desirable, certainly not for appearance, and I question if it would not betray a delicacy of constitution. Altogether the Show was a very wonderful one. What may we not expect at the Crystal Palace, when to young birds are added old birds also? "May we be there to see."—D., Deal.

### OXFORD POULTRY SHOW.

THE whole Show was a very great success, and reflects the highest credit on the Hon. Secretary Mr. King. We had feared the Alexandra meeting, so nearly clashing with it, would damage the entries here, but the poultry world has realised that the Oxford Poultry Show is firmly established. When we think that the Alexandra Palace was on the single-bird system, that its Pigeon schedule was one of the most comprehensive ever issued, that the Palace itself had insinuating powers, we quite come to the conclusion that the Oxford people must have thoroughly won the confidence of exhibitors to have the grand display they had last week. The Judges were—for poultry, Messrs. Teebay and Hewitt, the former gentleman taking the Game, Hamburgs, French, Game Bantams, Variety classes, and some of the Sale classes, while the latter judged the remainder; Messrs. P. H. Jones and Esquilant taking the Pigeons together. We thought the judging in most classes very good, and though in many instances the Alexandra awards were much altered, still we must remember that the birds were here in pairs, and many of the champion single birds of the Palace had here not nearly worthy mates enough to let them occupy the old positions. The feeding was good, and every bird had a sod of grass given it in the morning, and other green food in the afternoon. The pens were Billett's, and were well covered with chaff, and had as well a little grit. Every pen of birds by 12.30 on the Friday was in the railways' hands, except in one instance where a mistake arose about a duplicate number, but this we believe was speedily set right.

The sales were numerous, and the new tender plan was found to answer admirably. Among the most important sales we may mention that the cup Houdans realised £10 10s.; the first-prize White Pouter hen, £18; the cup Silver-spangled Hamburgs, £7; the first-prize Black Bantams, £30; the winning Gold Pheasants, £5 5s.; the third-prize Orpingtons, £6 6s.; a highly commended Polish cockerel, £6 15s.; second-prize Carolinas, £4 4s.; Mr. Copplestone's very highly commended Rouens, £5 5s.; the first-prize Black Cochins, £5 5s., and very many other pens at good prices. We must mention, too, the great

excellence of the local specimens; in many cases they were admirable, and this shows us in a most marked way that the Society is bearing fruit, for the great number of new county names and improvement in their exhibits is well worthy of comment.

The catalogues, which were ready when the Show opened with the awards in the margin, were nicely prepared. *Dorkings* were first, and a grand collection they were of sixty-five pens. In the Coloured, as in many other classes, we found several good birds but no very perfect pair; for instance, the cup pullet was a beauty, so was the third, and so was Mr. Walker's; while in cockerels the second, fourth, and highly commended pens of Messrs. Burnell and Hamilton were very good birds. On the whole, however, we thought the judging good, though we confess all through the Show we had a fancy for Mr. Burnell's cockerel in pen 8. Silvers were splendid, and here the champion cup went for Dorkings, and quite deservedly, as it should have done, too, in 1874. This year the cup pen, though very beautiful and perfect, was not to our mind quite equal to last year's first-prize pen of Silvers. Second were a nice pen, and about right; while the third were very young but of great promise. We thought it an admirable class and well judged. Whites were good, but we liked the second-prize pen best, for here the cockerel was equal to or better than the winner, and the pullet certainly superior. Third were a fair pair; the cockerel looked smart and fresh. In Cuckoos the winners were good. We note a great improvement in the tails of this breed, but not much extra size. The winners were well placed, the second going to a very nice pen of single-combed birds.

*Spanish* were a large class, but the quality disappointing. On the whole the winners seemed well placed. The cockerel in the second-prize pen was immense in face, but coarse. The pullets in 69 (Wilkinson) and 72 (Walker) were very nice and promising birds.

Buff *Cochins* were very fine; the prize pens and the second very highly commended pens were very even. We almost think we should have placed Mrs. Tindal first and second, as Mrs. Allsopp's second-prize pen had a very old and poor pullet—in fact, this lady must have penned her pullets, we should say, wrongly, for her best pullet was with her worst cockerel. The third-prize pen contained a lovely pullet—the same bird, we believe, that we noticed in our Alexandra report of last week with a young but soundly-coloured cockerel. Blacks were few and good. The second-prize pen must have closely pressed the winners, as it contained the best cockerel we have yet seen in Blacks for colour, comb, and shape. The third were right. 115 contained the Palace Black pullet, and a poor bird she is for a show specimen. Whites were a large class, and there were here many individual birds good, but with faulty companions. The winning cockerel was red on his wings, and the second-prize pullet looked as old as the hills, while the third-prize lady was almost stockless. Taking them as they were, our choice was for Mr. Faulkner's pen in spite of their very heavy hooks. Partridges were grand, and the winners well placed.

*Brahmas* were good, and the judging very nearly perfect in the Darks; for though something could be said, perhaps, against every pen, still they were well selected. Mrs. Baillie-Hamilton's bird has a nasty tumour on his breast, or else as a cockerel he was, perhaps, the best. After the winners we liked Mr. Bircho's pen and the pullet in 144 (Bennett). Lights were capital, but here, too, we saw several grand birds, but no very splendid pairs. Perhaps we liked the fourth-prize pen as well as any, but here the cockerel had a hideous comb. The second were stylish chickens, the same pair as won first at Edenbridge. 175 (Saville) had a nice pullet, so had 186 (Petter), while 178 (Haines) had a very fair cockerel; but the class was a difficult one to judge on account of the non-matching of the birds in their pens—in fact, the whole Show was remarkable for this.

*Game* were on the single-bird system, but the quality was disappointing though the numbers were good. Black Red cockerels were not a grand lot, and the only bird of any style or promise was the third, which will in time make a good one. Pullets were better; Mr. Dutton's pens were as good as any, but all the birds seemed backward. In Brown Red cockerels the winner was well to the front. It was a much better class, and the noticed chickens were all birds of good stamp and style. The Brown Red pullets, too, were a pretty lot of birds, and the winners nicely selected; we know the Judge took an immense deal of trouble over them. In the other two classes Duckwings carried off most of the prizes. We liked the cup bird immensely, and thought he merited his place, though we should have placed third over the second-prize pen. In pullets the winner was a good, and the second a fair Duckwing, third going to a pretty Pile. 309 (Forssyth) a nice Duckwing pullet. We thought the local Game entries exceedingly good and the birds well shown—much above the local average.

*Hamburgs* were wonderfully good, and the entries numerous. Golden-pencils made a fine class. We almost liked the second pen best, the cup cockerel somehow not being quite our fancy, though a fine chicken. Third were fair birds. Mr. Cresswell's

pen (819) were well marked, and 822 (Clayton) had a capital pullet. Silver-pencils were fair, and the winners properly placed. 849 (Hansor) a smart cockerel. Gold-spangles were a fine lot, and here we understand was a complete *bouleversement* of the Alexandra winners. The prize birds were good, and the cockerel in Messrs. Duckworth's pen and Mr. Long's pullet certainly were capital specimens. Silver-spangles were a beautiful lot, and winning difficult. We liked the second-prize pen as well as any, though the cockerel here was not worthy of his pullet. The third pair were good, and deserved their place easily. 882 (Hallam) were good, and 892 (Beldon) contained a very smart pullet. Blacks were very fine. The winning pair splendid in bloom and points, and properly the cup-winners. The second-prize cockerel was too high in tail, but his pullet capital; third, too, was a nice pen. 897 (Hoyle) had a smart cockerel, and 402 (Long) a finely-coloured pullet.

*Polands* were admirable. Blacks came to the front wall. The quality was very even, and it must have been almost a toss-up which of the three prize pens was to be first. Mr. Fearnley's cockerel was perhaps the best cockerel in the class, but his pullet very poor in crest. In the other class Mr. Adkin's Silvers were charming, being really good in crests and markings. These won first and third, a fine pen of Golds taking the intervening place. Mr. Beldon's pen was a grand pair, and Mr. Galloway's pen (424) were of great promise, and soon found a new home for £3 8s.

*Houdans* were a grand lot, and the judging exceedingly difficult, for the type of birds in so many pens was very different. We thought the best pen won, the crests being splendid, and the markings of each bird matching well; second and third were good pens. The fourth we did not like; they had nothing in common, and we infinitely preferred 448 (Dring), 459 (Wood), or 468 (Handley); in fact we think the first-mentioned might safely have been placed higher still. *Crèves* were a capital lot, and the winners perhaps well placed on the whole, though we liked either of Mr. Knight's pens or Mr. Wood's as well as the third-prize pair; first and second being very good.

*Of Malays* there were very few. The winners were good, though all the highly commended pens closely pressed on them. The only White pen were large and good in points, but horrible in colour.

*Americans* were two capital classes. We should think as layers they will be appreciated. We confess our *penchant* is for the Whites; we have seen them on a green run, where they certainly look very elegant. But the Brown is the hardy variety, we hear, and we think will soon make themselves known as useful fowls. We did not care for the cup Browns, and thought Mr. Kitchen should have had it, though the third-prize pullet was very pretty. In Whites we liked 526, or even 527 (Fowler) as well as any pen. The third went to Plymouth Rocks.

*Silkie*s were a charming class, but we could not agree with the awards: crests, colour, combs, all had to give way to leg feather. This we think positively ridiculous, for the latter is easy enough to obtain, while the former points are very difficult. But we hope to publish in this Journal soon one or two articles on this breed, when we will state our views on the matter, as perhaps we have given as much time and trouble to the variety as anyone. As it was, undoubtedly the best pen in the class was Mr. Stephen's, and perhaps next to it Mr. Cresswell's; Mr. Nicholl's pen (539) had a comb like a Hamburg's, and several pens had visible proofs of vulture hocks, which should at once be condemned.

The Variety class was good; a splendid pen of Sultans were first, Black Minorcas second, and Scotch Dummies third; good Sultans, Minorcas, and Scotch Greys coming in for high commendations.

*Bantams* were exceedingly good, the Game especially so, but the Black Bantams were the cream of the lot; every noticed pen was good, and many others as well. Sebrights were beautiful, exquisite Silvers winning first easily. We were glad to see the quality here so good. In the Variety class Pekins were first, and White Rose-combs second and third. There were several good pens of White-booted also, and we think a class here would pay well. Mr. Bloodworth's pen of White Rose-combs were the Palace winners, but the cock had his tail pulled out *en route* to the Show, or they would have been most probably near winning.

*Ducks* were grand. We wonder if a better Aylesbury drake than the winner was ever shown; his colour, size, and shape are simply wonderful. Rouens were good, and judged by weight we believe. Fancy Ducks made a most attractive class where Mandarin, Carolinas, and Spotted Bills drew the winning cards. Blacks were lovely, and in a perfect light. The winners were well chosen, and the awards most favourably received. Mr. Sainsbury has good colour and small size this season. Calls only mustered three pens, all good; but this class will die a natural death we may as well state here, unless eight entries are guaranteed in 1876, at least so we hear.

*Geese* and *Turkeys* were wonderfully fine, and the Aylesbury

pair again scored another triumph in the former class. Every pen in the Turkey class was noticed, and the quality was exceedingly good throughout.

The Selling classes were very large, and many pens changed hands. We noticed here several pens of Buff Cochins of more than ordinary merit. The second-prize Buff pullets realised £5 5s. by tender. We are assured Cochins are generally looking up and are in great demand. We are glad to hear of it, for we owe a great deal of the mania to the first-introduced Cochins, which set the market going and created such a *furor* in by-gone years.

#### PIGEONS.

The Pigeons are always a great feature at the Oxford Show, and well they may be when sixteen silver cups are offered for them. They were charmingly shown in the Town Hall, out of the general noise of the Poultry Show, and we must say that we rejoice in still seeing here and there the smaller varieties shown in pairs. Even for Oxford the Show this year was a remarkable one, and we heard that the Judge considered the classes of Blue and Silver Turbits and of English Owls the best he had ever seen.

Carriers headed the list with six classes. Blue or Silver had two classes. The cup went to Mr. Hammock's bird, a Blue of immense length and fine form and skull; apparently not an old bird, for his wattles were not yet much developed. Second cock a Blue also, without the length of the first, but a good bird, excellent in tail and wattles. Third, another Blue in good and sleek condition. The hens were a fair class, the first a Silver Dun with somewhat watery eyes; second a long and fine-headed Blue, not in first-rate condition; third a fair Blue. In the two classes for Any other colour the cup went to Mr. Fulton's noble Black cock, a grand bird in all points; second in cocks was a Dun, but slightly his inferior in head and wattle, belonging to the same exhibitor; third a Black with long fine form. The first local prize went to a creditable Dun, which we saw was claimed at £7. In the class for hens Mr. Fulton repeated his victory, taking first with a Black and second with a Dun. Young birds had two classes and two cups. That for Blue was carried off by Mr. Stretch with a bird of great promise, his head and wattle will some day be magnificent; second was also a very stylish bird. In the other class, Mr. Simpson's cup bird was a Black in a bloom of condition which it is delightful to see; second was another Black, running him hard; third a Dun of peculiarly rich colour and striking form. Col. Hassard showed a good Dun, deservedly very highly commended, though not equal to the third-prize bird. Pouters had two classes for Whites, which were beautifully filled, and two for Any other colour. Mr. Heath's first-prize White hen was a most remarkable bird, and though entered at twelve guineas was claimed. The first-prize White cock was a bird of extraordinary limb. If we mistake not a cock or two passed for hens in the class assigned to the weaker sex. In the two classes for Any other colour the cup went to a Black-pied cock, a fine bird but a little looser in crop than we like; the second cock was a Red; the third a Blue, particularly good in colour. In the class for hens first and third were Blacks, the third not equal to the first in points, but excellent in colour; second was a Yellow. Barbs.—The cup for the best pair of Barbs or Tumblers was awarded to the first pair of adult Barbs, magnificent Duns; second were Blacks; third Duns in beautiful bloom and condition, though not equal to their wondrous predecessors in head. In the class for birds of the year, first were Blacks, which we did not think remarkable; second promising Duns; and third nice Yellows. Owls were a splendid collection—in fact, we suppose the Owls, Turbits, and Magpies were as good classes of the kinds as have ever been seen in one show. In English Owls the winners were all good, but we thought Mr. Allen's hardly had justice done to them; but the cream of the two classes was the cup pen, they were perfect gems and a show of themselves. Rants only came four pens strong, and Nuns only five, but the quality was good, and we wonder the former variety especially does not muster more supporters. Turbits were truly grand. We liked one or two pens quite as well as the winners. 1215 (Hardy) had a splendid bird. In the other class exquisite Blacks were first, really a pair of gems. In the second-prize pen of Reds the hen is a wonder, perhaps the best in the fancy. Third good shell-crested Blacks. Mr. Cresswell's birds are all so extremely good in gullet. Fantails were good, and we should think two classes would pay here another year. Mr. Serjeantson's were wonderfully nice. We noticed a nice pen of Blacks and another of Blues, but the whole class was very fine. Jacobins were a nice lot, beautiful Yellows first and second, and third good Reds and Whites; the latter pen perhaps the best. 1256 (Cresswell), a nice pair of Reds. Trumpeters, six pens, but Mr. Schweitzer's and Mr. Lederer's pens were empty. The winners were all Russians, all good, and all Black. Magpies were, as we said above, two beautiful classes. The first-prize Blacks were quite exquisite and admirably shown. The other class was also admirable, and Mr. Baker's winners well selected, the second Yellows, however, coming near to them.

the result is a coldness when they meet, or, worse, absolutely avoiding each other. I have heard of even worse still—viz., that a difference about a feather, or the shape or colour of a bird, has broken a former friendship. This is deplorable. Soon the great gathering of fanciers will take place at the Crystal Palace Show, and I hope when it comes, so near Christmas too, that no fancier's hand will be given or taken other than kindly, and not one will look into the pens in order to avoid looking at a former friend.

Having finished my little homily on "brotherly kindness," I will say a word about the Jacobins. I see there is a point—an artistic point I may call it—in the dark thighs which I had not noticed, as they give a balance to the eye, which takes in profile the whole frill, and this Pigeon should be long and boat-shaped. As to the low cut, I mean only just a little low, the white coming in a narrow line below the back, which prevents what has to me a kind of choked appearance.

By what I hear we shall see some splendid Jacobins in colour and points at the Crystal Palace Show.—WILKINSON BROTHERS.

### NORWICH BIRD SHOW.

THE Norwich Alliance and East Anglian Ornithological Association held their third grand annual Exhibition of Canaries, Mules, and British and foreign cage and song birds (open for competition to the United Kingdom, in St Andrew's Hall, Norwich, on Friday, Saturday, and Monday, October 20th and 21st, and November 1st, 1876. The Exhibition was tastefully arranged with plants and shrubs kindly lent for the occasion by the Messrs. Ewing of the Royal Norfolk Nurseries, Baken. The Show was a capital one, more than nine hundred birds having been entered for competition and sale. Messrs. Mackley of Norwich won two silver cups and an electro-plated teapot and mustard-pot. Mr. Fairbairn of Canterbury won a silver cup, as did also Mr. J. Theobald of Bristford, and Mr. E. Hawkins of Leicester Square, London. Mr. W. A. Blakston judged.

**NOVEMBER.—Clear Yellow.**—1, G. & J. Mackley, 2, Burwell & Wright, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Tinted, Unusually-marked, and Variegated Yellow.**—1 and 2, G. & J. Mackley, 3, J. Adams, 4, J. Theobald, 5, J. Adams, 6, E. Moller, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Marked Crested Yellow.**—1 and 2, G. & J. Mackley, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Yellow, with Clear, Grey, or Dark Crest.**—1, F. Woodward, 2 and 3, G. & J. Mackley, 4, C. J. Bell, 5, J. Adams, 6, J. Theobald, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Clear, Tinted, and Variegated Yellow.**—1, Mrs. J. Horn, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Golden-spangled, with Broken Cap or Pied Wings or Tail.**—1 and 2, T. W. W. Fairbairn, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Golden-spangled, with Broken Cap or Pied Wings or Tail.**—1, E. Ritchie, 2 and 3, T. W. W. Fairbairn, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Clear Yellow.**—1 and 2, J. Theobald, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Variegated Yellow.**—1 and 2, J. Theobald, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Yellow Moustache.**—1, G. & J. Mackley, 2 and 3, E. Fleming, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Yellow Moustache.**—1, J. Theobald, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Yellow.**—1, J. Adams, 2 and 3, J. Caplin, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Yellow.**—1, J. Adams, 2 and 3, J. Caplin, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

**NOVEMBER.—Yellow.**—1, J. Adams, 2 and 3, J. Caplin, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

(Champion and Males and Canary). 2, W. Carrich (Greenback), 3, E. Chapman (Lancet), 4, G. Cook (Dark Lancer), 5, E. Hawkins (Main between Champion and Canary), 6, W. & C. Burdison, 7, J. Manton (Brown Lancer and Goldfinch), 8, G. & J. Mackley (Lancet Male) (2).

### GROUPS.

1.—Irrespective of colour.—1 and 2, G. & J. Mackley 3. 1.—Three Yellows and Three Reds.—1, A. Palmer, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

### BRITISH BIRDS.

1.—Three Yellows and Three Reds.—1 and 2, G. & J. Mackley 3. 1.—Three Yellows and Three Reds.—1, A. Palmer, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

### FOREIGN BIRDS.

1.—Three Yellows and Three Reds.—1 and 2, G. & J. Mackley 3. 1.—Three Yellows and Three Reds.—1, A. Palmer, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

1.—Three Yellows and Three Reds.—1 and 2, G. & J. Mackley 3. 1.—Three Yellows and Three Reds.—1, A. Palmer, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

1.—Three Yellows and Three Reds.—1 and 2, G. & J. Mackley 3. 1.—Three Yellows and Three Reds.—1, A. Palmer, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

1.—Three Yellows and Three Reds.—1 and 2, G. & J. Mackley 3. 1.—Three Yellows and Three Reds.—1, A. Palmer, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

1.—Three Yellows and Three Reds.—1 and 2, G. & J. Mackley 3. 1.—Three Yellows and Three Reds.—1, A. Palmer, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

1.—Three Yellows and Three Reds.—1 and 2, G. & J. Mackley 3. 1.—Three Yellows and Three Reds.—1, A. Palmer, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

have made the rash assertion of allotting worker bees nine months as their span of life. Why, at this rate a May swarm whose queen lays two thousand eggs per day would increase her subjects in the three summer months to 212,000! Allowing one-third deaths by casualties, would still give about 28 lbs. weight of bees and brood as the inhabitants of the hive! I believe I have stated that in summer, when bees work hard, six or eight weeks is the limit of their days. Mr. Pettigrew doubtless refers to me as the writer who is responsible for this statement; I accept the responsibility, and I even believe that one or two weeks may be deducted from that short span.

The substitution of an Italian queen for a common English one has now become one of the commonest of all apian operations. I venture to say the experiment has been repeated five hundred times during the season just past, and where three months have elapsed, and the queen proved fertile, none of the black workers remained. In the case of a Ligurian queen being now introduced when breeding has almost ceased, black workers will be found in April, but not after the May sun has warmed the bees to activity. Where a stock is queenless over the winter, the workers having no work to do will live longer, but certainly not nine months under any circumstances whatever. Idleness prolongs life in the worker and queenlessness in the drones, some of which I last season kept from September till April, when the last disappeared. I cannot find who has said the young destroy the old bees and push them out of the hive. This is not my statement or experience.

Many of our best apianists now use nine with 8-16th perforations as adapters between hive and super. I have never heard of an instance of brood being found in the latter when such were used. Can Mr. Pettigrew say it is an uncommon occurrence when admission is given through a large aperture?—JOHN HUNTER, *Eaton Rice, Basing.*

#### BRITISH BEE-KEEPERS' ASSOCIATION.

THE Committee at their last meeting practically reversed the Judges' decision in regard to Mr. G. Fox's splendid super, by expressing their belief in the *bona fides* of Mr. Fox's statement, regret at the Judges' award, and voting to Mr. Fox the silver medal of the Association in acknowledgment of the exhibitor's skill as a bee-master. The Committee may be congratulated in making all the amend in their power in regard to this unfortunate occurrence.

#### HIVE COVERS.

IN answer to the request of "CAROLUS" I have to say, that though hives are often well protected from the weather by close wooden bee-houses, I have never seen one that I considered convenient. I have seen some very ornamental and costly, and some very rustic and ancient. The best I ever saw was a large

sooner done when they stand singly and separately. [All my hives stand singly on three posts, and are covered with roofing felt for the outer covering, and old carpets or cocoa-nut matting under the felt. The felt is waterproof, portable, convenient, and durable. By warming it at a fire when first used it becomes as soft as flannel, and in this state it should be fitted on. Nest straw covers are more pleasing to the eye, and are excellent protectors both in winter and summer, but they are not so durable and portable.]

Fig. 89.

On paying a visit to Mr. Bagshaw, Longnor, Buxton, some three years ago, I found his hives standing about 6 feet apart, and securely protected from the weather, each hive being placed in a neat ornamental wooden house wall painted. Eighteen of these small ornamental houses standing in three rows greatly improved the appearance of his garden. These houses are about 2 feet deep and 2 feet wide, with moveable overhanging covers. The covers or lids are as easily moved as felt, and the hives as easily lifted for examination and replaced. Neither wind nor rain can touch the hives inside. The houses are wide enough to hold some warm materials between their sides and the hives, and are deep enough to admit supers being placed on them. If a prize were offered for the best covers, I think

Fig. 88.

round wooden house, about 11 feet wide and 10 feet high, with two shelves running round it; one shelf about 8 feet above the other. So far as protection from the weather goes nothing could be better, but they are inconvenient in many respects—indeed, all the bee-houses I have seen are inconvenient (in the way) when the bee-master wants to examine the hives they contain. I examine my bees frequently during the summer, by turning them up to see how they are working and progressing. In this way I ascertain when the hives should be swarmed, supered, and eked. The work is much easier and

Fig. 90.

Mr. Bagshaw's would easily gain it. At all events I have seen nothing equal to his for completeness, convenience, and durability. The square houses or boxes complete cost 15s. each, and the octagonal boxes 20s. each, made and painted at Longnor. They cost more at Sale, wages being higher there. The woodcuts will give "CAROLUS" and others some idea of what I have been writing about.—A. PETTIGREW.

I find nothing so neat as ferns. If these are cut dry at this season they have a rustic appearance, and are quite as durable as straw. I take a bundle about the size of a wheat-sheaf, and tie the bottom ends together; then open the sheaf in halves, and place it firmly on the top of the hive; then arrange the fronds regularly round the hive. I tie them round the hive with willow bands, and clip the ends below the floorboard.—R. H. D.

### ANOTHER YEAR'S EXPERIENCE.

A GENTLEMAN in Ireland asks what effect or impression has been made on my mind by the use of large hives since the 'Handy-Book of Bees' was first published. He is evidently a little distrustful of what has been said in their favour. Our own opinions as to their value and superiority have been pretty strong and well established for thirty years, but every year's experience furnishes us with incentives and encouragements to do what we can to enlighten public opinion on the question.

From all parts of the country we hear of successes from the use of large hives of simple construction that were never dreamed of before their introduction. And all who give them a fair trial in a good season become inspired with confidence in them.

The logic of facts, and outside pressure, may, perhaps, induce the Managing Committee of the Bee-keepers' Association to offer prizes for the heaviest swarms, and the greatest results in honey and comb from one stock hive managed on any system. If this be done we shall probably find results approaching 3 cwt. of honey and combs exhibited as the produce of one stock hive and its swarms. Last year we suggested the offering of prizes for heavy hives and their swarms. We shall be pleased if one or two gentlemen offer a handsome prize next year for such hives and swarms.

Even this year, which has not been favourable for bees, some stock hives rose in weight to 90 lbs.; first swarms to above 100 lbs., and second swarms, or turn-outs, to 90 lbs. If the British Bee-keepers' Association continue to seek novelties and "fancy goods" (as the Hon. and Rev. Mr. Bligh calls them), instead of seeking the best results produced in England, it will, we think, become the apirians of this country to do what they can to induce the Royal Agricultural Society of England to take bee-culture under its fostering wing, for honey is as much a product of the soil as milk or meat.

**SWARMING AND NON-SWARMING.**—On this point, too, history repeats itself in favour of the swarming system of management. In good seasons for honey swarms become heavier than stocks that never swarm at all, and the mother hives and second swarms rise to 70, 80, and 90 lbs. each. No such results can be obtained on the non-swarming mode of management. Besides, on the swarming system the apiary may be kept full of hives filled with young sweet combs, and possess young queens; on the non-swarming system queens become old, combs become black, tough, and ugly, often pollen-bound and distempered with foul brood. Bee-farmers especially find it to their interest to let their bees swarm. Honey run out of the comb is more saleable here and in many other places than honeycomb. Our object, then, is to obtain the greatest weight of honey, and we obtain this more certainly from two or three colonies of forty thousand bees each than from one of no greater strength.

Another year's experience urges us to recommend swarming in preference to non-swarming, but both may be practised in one apiary. This year we obtained an unusual amount of pure virgin honeycomb, not from supers, but from the hives of swarms. In emptying these the pure comb was placed on dishes and in clean hives on one side, and the darker combs containing honey were placed on the other side. From some of these hives we had as much pure virgin combs as would have filled three ordinary-sized supers. Though most of the run honey is sold, we have great heaps of beautiful comb on hand. To be sure we have an order from a distant city for all we have at our own price, but as it is not in supers we fear it would not carry well so far. These things are mentioned to let amateurs know that with large hives managed on the swarming principle they may always have a good supply of honeycomb.

Another year's experience has tended to open our eyes to the importance of spring-feeding if the weather be unfavourable. Slow continuous feeding, say a halfpenny worth of sugar given to a hive daily during the spring months, whether it has honey or not, encourages the bees to breed, and greatly tends to health and prosperity. Great assistance, too, is afforded to swarms after they are hived by feeding when the weather is unkindly.

Keeping hives warm and dry during the winter and spring months is a matter of greater moment than most apirians think. Bees are easily chilled into helplessness. Hard frost and severe winters try them sorely. Life in winter, while the mercury indicates 20° of frost, is one of suffering to bees. The winter of 1859 or 1860, which brought down the mercury to zero, destroyed thousands of hives. All hives should have their doors contracted now, and be well protected by coverings of some kind. An additional under garment is often a great comfort and protection to the human frame in cold weather; and

bee hives in the open air cannot be too warmly covered. Soft dry hay and woollen rags well stuffed beneath the outer covering of hives afford great comfort to bees. Even three or four large newspapers wrapped around hives protect their inmates much. The outer coverings should be sufficient to shed every drop of rain that falls on them.—A. PATTISON.

### OUR LETTER BOX.

**ADDRESS (W. H.).**—We cannot reveal the address of correspondents. If you will enclose a letter in a stamped envelope we will forward it.

**HEN'S VENT TUMOURED (A. B. C.).**—Cut away all the clogged feathers, and with warm water wash and cleanse thoroughly the affected part; afterwards anoint thoroughly with goose grease or lard the skin and flesh all round the vent, and repeat the dressing daily while necessary. If the bird seem heated or feverish in the skin give a strong dose of castor oil. Plenty of green food should be given daily.

**BELGIAN MODE OF RABBIT-KEEPING (J. M. Derby).**—The Belgians keep their Rabbits very much the same as we do, but they have time and a great choice of food at a very small cost. The breeding adults are kept in small pens or boxes in half darkness, and the young when weaned are turned into large cages or pens to fatten for the table. We think the very small cost of produce has more to do with the amount of profit than any particular system followed. There was formerly a large establishment for rearing them at Nieuport, about ten miles from Ostend.

**WATERPROOFING CANVAS (A Subscriber).**—Paint one side of the canvas with coal tar in which a small quantity of fat is dissolved, and powder over the tarred canvas some slaked lime.

**VENTILABLE PARCHMENT (F. E. S.).**—We believe it is made by applying sulphuric acid to paper, but how or in what proportion we do not know.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

27th.—Cold and damp all day.  
28th.—Fair, but dull, and at times very dark all through the day.  
29th.—Cloudy and dull all day, but without rain.  
30th.—Fair all day, but cloudy and cold.  
31st.—Hazy early, soon clearing off; a fine though cold day; very bright about 3 P.M.  
Nov. 1st.—Fair and pleasant all day; but at no time bright.  
2nd.—Another fair but dull day; slight rain at night.  
A very cloudy dull week, almost without either sun or rain. The mean temperature generally about 5° lower than that of last week; the mean maximum in sun was more than 17° below that of the preceding week.—G. J. SIMONS.

### COVENT GARDEN MARKET.—NOVEMBER 3.

THERE is very little alteration to quote this week, and with trade still quiet prices remain much the same.

From observations taken near London during forty-three years, the average day temperature of the week is 49.2°; and its night temperature 84.1°.

### THE ROSE ELECTION. DECLARATION OF THE POLL.

**I**N giving to the readers of our Journal the result of the election of the newer varieties of our national flower I must commence by regretting that the declaration of the poll has not been delivered in the past month. This was my full intention, but "circumstances," to use a common but trite saying, "over which I had no control" have given me but scant time for entering into this election as fully as I desired, and have compelled me to defer the result. The difficulties are probably greater than most persons imagine. The necessary correspondence is great; rarely is one exchange of letter sufficient for each elector; there is a difference of opinion as to the age of a Rose, or too many Roses are named when a limited number is asked for—in fact a variety of circumstances which necessitate the interference of the returning officer to render the returns complete and reliable.

Then some reply, *Cui bono?* The best answer to such a question is the fact, that one firm in the north advertised last year the fifty best Roses as brought out by the 1874 election, simply altering two Roses that did not suit the northern elements; whilst another eminent rosarian in the trade advertised week after week the twelve best new Roses as brought out by the 1875 election, which election he had positively declined to assist! I smiled at the advertisement, thinking it a curious corollary to the refusal. These are, I may say, public avowals of the utility of the election. Private letters equally attest

the fact that the returns are looked forward to with interest; whilst a paragraph like the following speaks for itself—"I have ordered every Rose not in the fifty to be discarded." It is indeed tolerably clear that, although the electors are not infallible guides and are all liable to crotchety notions here and there, yet the general *résumé* of the whole election is a fair index of the value of a Rose. Indeed, the wish expressed by some writers in our Journal that this kind of election should be extended to other flowers and fruits, is in itself an admission that the election is of value.

In the present election of the newer Roses—that is, those introduced since 1869, including that year, there is the difficulty of the age of each candidate. I have before expressed the wish that some enterprising rosarian in the trade would give us a catalogue with the age of the Roses attached. Some of the electors have expressed to me the same thought. I believe such a catalogue would be warmly appreciated. This very point makes this election of the newer Roses a greater difficulty than it would otherwise be; and there are some Roses in the lists that appear to me to take copy by some of us mortals and profess to be younger than they really are. Roses, not being equine, have no teeth on which to pin our verdict. I have my doubts as to Emilie Hausberg and Dupuy-Jamain, even though a leaf of a catalogue was sent me in which both were marked as Roses of 1869. Had they been so, I cannot but think that somebody in the election of 1875 must have named these two beautiful Roses, but they were on that occasion voteless. This would hardly have been possible; the names, however, stand. With this introduction I lay the declaration of the poll before our readers.

The columns, &c., are as heretofore: First, the No. denoting the position of the Rose, then the name, age, and kind of Rose. Letters A, B, and C represent the amateurs' votes, the same letters with an asterisk (\*) the nurserymen's. The last column is that which decides the position of the Rose, the gross total. A and A\* denote each the number of first-class votes—viz., in the first twelve each Rose has received; B and B\* the number of second-class votes; C and C\* the totals of amateurs' and nurserymen's votes respectively.

Thirteen Roses received three votes each, a like number only two votes; the remainder had but a solitary champion

to express partiality for them. Altogether, by the twenty-four electors, 107 Roses were named in the twenty-five

and, very curiously, fifty-four, or a fraction over half that number, were named as in the best twelve, no less than nine of these having only a solitary vote.

One of the most valued contributors amongst the amateurs has suggested that the election of newer Roses should be confined to the three previous years. There is something to be said for this proposal. I, with all deference, think there is more to be said against it. The proposal will suit those to whom money is no object, who will buy the highly-vaunted candidates for English money, *coute qui coute*, and if they turn out worthless dispatch them to make room for others. But our Journal does not write for this class alone, but has always striven to help those who looked at both sides of a shilling before spending the same in Rose-flesh or otherwise. Now to these it is sometimes a matter of doubt whether it may not pay better to have a newer Rose at 8s. rather than two at 1s. 6d. Now the present election is a case in point. There is a recent introduction comparatively, *Capitaine Christy*, an 1878 Rose, running close up for the premiership, losing it in fact only by "the skin of the thorns," the only teeth a Rose has. Better still, there are two 1874 Roses, *Perle des Jardins* and *Marie Guillot*, that are also instances—cases, in fact, where an intending purchaser might decide to lay out the larger sum on account of the position of these Roses; but this position could hardly be so manifest if only the last three years were taken. Then, again, to me it adds considerably to the interest of the election to mark how old friends hold their ground. In this respect I think the election of 1878 as compared with the present offers marks both of interest and utility. For example, in 1878 several Roses were placed highly which are in this election wholly out of the running—viz., *President Thiers*, No. 11; *Lyonnaise*, 13; *Madame Lef. Bernard*, 15; and *André Dunand*, 16. Now, where are these Roses in 1878, when, be it remembered, we have twenty-five Roses named instead of twelve, as in 1873? One alone appears in the return, although forty-six Roses are named instead of twenty-six! and this Rose, *André Dunand*, has only four votes, *Lyonnaise* has only three votes, and *Thiers* but two. What a fall is here! These Roses appear, in fact, to deteriorate. On the other hand some, as *Marie Van Houtte*, *Madame Hippolyte Jamin*, and *Belle Lyonnaise*, have greatly improved their position. Such comparisons I fancy have their value.

In the election of 1878 I ventured to remark that *François Michelon* would probably run *Etienne Levet* very closely for the premiership of their year. They have now an equality of votes, the latter having slightly the better class of votes. *Catherine Mermet*, too, though standing well in 1878, has very deservedly risen; few Roses are more lovely, and she enjoys a harder character than many of her class. Of *Madame Lacharme*, for and against whom so much has been said, the verdict is favourable, two-thirds of the voters naming her, but mostly in the second division. Under glass there is no doubt that she can be beautiful, but in the open she can be coy in exposing her charms.

I hope in a fortnight's time to publish the result of the Roses as tried by the noses; meanwhile I desire to express my grateful thanks to all those who have kindly contributed to make the present return of any value by sending in voting papers. Without them the election would indeed be null and void.—JOSEPH HINTON, *Warminster*.

### RASPBERRY CULTURE.

WITH reference to the difficulties of "A LADY GARDENER" in growing Raspberries, I would advise her to have the ground where she is intending to grow her plants well trenched, and after all is in readiness and the ground not too wet, have pits taken out where the plants are to be placed sufficiently large to hold one good barrowful of thoroughly decayed vegetable refuse, and incorporate it well with the soil before planting, and to fork-in a liberal dressing of the same material every year round the roots and all over the ground. If she adopts this simple mode of treatment I think she will succeed.

I have seen the strongest canes and the best fruit I ever saw picked from plantations thus treated, and where every other kind of dressing had been tried and failed to produce satisfactory results. I invariably adopt this mode of cultivating the Raspberry, and I have not yet had any cause to change my practice. I have, however, not had the opportunity of seeing it tried in town gardens.

If "A LADY GARDENER" should try the plan she might

kindly give us the results of her experience, as, if she does succeed, her experience would be of benefit to others similarly situated.—JAMES FAIRWEATHER, *Halston, Orcestry*.

### SOIL AND CLIMATE IN RELATION TO PRACTICE.

I AM not unacquainted (see page 355) with the use of burnt clay, charcoal, charred rubbish, &c., having very early in my gardening career seen the benefits arising from their free use. This will be understood when I say that I received my first horticultural lessons at Shrubland, where Donald Beaton kept a man continually burning clay for the use of the gardens, and where he left on his retirement a legacy of some thousands of tons of it for the use of his successors. Although I had not the advantage of actually working under the directions of the good old man I was well acquainted with him, and commenced my employment in the gardens a few weeks after he left.

Now, to show that I have not forgotten my early lessons, I may say that if I do not use much burnt clay for reasons which I will presently explain, I use what is preferable in many ways—wood charcoal in large quantities.

For planting fruit trees, and also for growing plants of all sorts in pots, it is almost the only thing used for keeping the soil sweet and open. I have not used a ton of sand in six years. Hard burnt clay would also keep the soil sweet and open—I mean clay which was not smother-burnt, for very stiff clay cannot be burnt in that way. But charcoal does more than this. The plants have actually the power of dissolving and feeding on it, it therefore enriches the soil; most other things used for keeping it open impoverish it.

Rubbish of all sorts smother-burnt is invaluable for garden purposes, and advantage should always be taken when burning rubbish of any kind, after getting a good body of fire, to cover it up with soil and leave it to smoulder away without a great quantity of air reaching the fire. All this I have known and practised for a long time, and I thought I knew all about it as well as a good deal about drainage; but since I have been here I have found out that I do not know all about it yet.

Not all clays can be burned profitably. I had one experiment on rather a large scale. A quantity of drainage was wanted for fruit borders; stones and bricks were not forthcoming in sufficient quantities, and I determined to burn clay for the purpose. I had it burned and it made excellent drainage, and also provided me with many tons of small stuff for mixing with the heavy soil. Well, I dare not tell the cost of the experiment. I had an old practised hand to do the job who had done a good deal of the same sort of burning on railways. Both wood and small coals were used for fuel, as we could not keep the fire afloat with wood alone; and I will let out this much of the secret, that on reckoning up costs I found it would have been quite as cheap to have used the black diamonds themselves for the drainage and saved the trouble of carting the clay about. Let not this, however, prevent others from burning clay, for it can be burned both easily and profitably if it is not of too tenacious a nature. If I am obliged to burn any more here I shall take a lesson from the brickmakers and have my material cut and dried, and then piled up so that air can circulate between it, for certainly it cannot easily get into it. My surface soil which has been worked and aerated for generations would of course burn; but its quantity already is much too limited, and to burn it would be taking a lesson from the very learned man who a few months ago was advising people to burn all their manure before spreading it on the ground! I wonder if he ever tried the experiment of living on calcined beef.

Mr. Luckhurst would like to know what has been done and what is intended to be done to ameliorate the crudity of my soil. I will endeavour to explain. The garden is well drained all over, and it has a very sharp slope, so that there is no difficulty in getting rid of the water. Well, then, all borders for wall trees are dug out their full width—12 to 15 feet, down to the hard bottom, which is not far to seek. This is made to slope sharply to the front, where there is a drain tile lowered a few inches into the clay and connected with the main drains. The hard bottom of the border is then entirely covered with stones, clinkers, bricks, &c., at least 5 inches in depth; for Peaches it is 10 or 12 inches. Turf is placed on the drainage to protect it, and then soil to the depth of about 2 feet. This raises the border on the side near the wall a foot or 18 inches above the surrounding ground.

Of course the trees are not planted in the stiff clay to which I have alluded. The soil used is such as would grow Peaches

in any favourable climate. So my fruit trees are not uncared for: they have the best of drainage and the best of soil my skill can devise. It is not the soil with which the trees have actual contact that is in fault and that could make a climate good or bad. It is the soil and subsoil of the neighbourhood which helps to keep the temperature low and the atmosphere humid. Draining my Peach borders is but like a drop in the ocean; it will not prevent the *Polypodium* luxuriating on the branches of the neighbouring Oaks, nor the moss growing on the tops of the hedgerows. The fogs will still rise in the neighbouring valley, and the midsummer frosts defy our garden walls.

My trees are altogether isolated from the natural soil, but they are not isolated from the atmosphere for which the natural soil and subsoil in the neighbourhood are partially responsible. Where Peaches are so isolated, as with glass, they do remarkably well. This year I have been also wonderfully successful out of doors, but I do not yet know whether the credit belongs to myself or to the season. I have learned a great deal since I have been here, and I have materially altered my practice. Time alone will show whether I am more permanently successful than my predecessors. I trust I have said enough to show that Oldlands is not the worst place in the world to grow Peaches.—WM. TAYLOR.

### ABRUS PRECATORIUS.

THE above is the name of your ("OLD QUEEN") plant raised from seed received from the West Indies, and now "looking sickly." Its browned hue is but the natural tint of

which need rest need also support. The soil of all deciduous plants must be perceptibly moist throughout the winter, or the rest to which they are subjected may be the rest of death as it certainly will lead to impaired health. We mention this now as the period when errors in over-resting plants and trees may be made, thoughtlessly by some and systematically by others. With a low temperature and moisture in the soil plants have rest and at the same time support, but total dryness of the soil is an evil ever to be avoided alike with hardy trees and shrubs and tender plants.

Let your plants, therefore (a specimen of which we figure), have rest, but let that rest be reasonable. Keep the plant cool but in a not lower temperature than 55°. With an increase of heat in the spring it will start into growth, and may then have fresh soil given, taking the old soil away partially, but shaking-out the plant entirely. A mixture of equal parts of loam and peat with lumps of charcoal and a tenth part of silver sand will be a suitable compost. It is the Wild Liquorice, native of the West Indies; it is a pretty stove-climbing plant, its pale purple flowers being attractive and its foliage agreeable; it is of easy culture, and readily propagated from cuttings inserted in sand and placed under a bellglass in the spring. Its roots possess the same property as the Liquorice of commerce, but the seeds if eaten are apt to produce violent headache.

### ROYAL HORTICULTURAL SOCIETY.

THE following address from the Council of the Royal Horticultural Society has been issued to the Fellows along with the list of privileges for 1876 which we published last week.

The address sets forth very clearly the present state of the Society and the necessity there is for such arrangements as the Council have made for next year. The pernicious abuse of the transferable tickets which have hitherto been issued to the Fellows has very materially contributed to the reduction of the Society's income, by extending the privileges of the Society to those who did not contribute one farthing towards its maintenance. Notwithstanding the enormous increase of the neighbourhood during the last ten years in extent and population, the income of the Society from subscriptions is very much less now than it was ten years ago. The system of lending and borrowing tickets, which had become prevalent, had its natural consequence, and those who were benefited by it had no need to subscribe to the Society's funds. It is, therefore, against this abuse that the Council have been careful to provide in the new arrangements for 1876. All transferable tickets have been abolished, and every Fellow or Fellow's nominee will have to show their tickets on entering the garden as they would to any place of public entertainment.

To compensate for the loss of transferable tickets the Council have acted most liberally towards the Fellows. Every four-guinea Fellow will have three tickets, one for himself personally and the other two for his nominees. He will also have the privilege of procuring for each adult member of his family personal tickets at the rate of one guinea each, which will admit on all except specially reserved occasions; and a two-guinea ticket will admit all the junior members of his family under twelve. To illustrate this we will suppose the head of a family is a four-guinea Fellow. He receives one ticket for himself, one for his wife, and one for an adult member of his family, admitting three persons for four guineas. If he has three more adult members of his family, he can by the payment of one guinea each obtain three more tickets which will admit them also to full privileges. Thus by a payment of seven guineas six members of a household are admitted to all the benefits arising from the daily use of the gardens, admission to all shows, promenades, fêtes, and conversations. And where, it may be asked, is there in all the metropolis a fashionable suburb which has at its doors a resort and attractions which can be obtained on such terms?

Fig. 91.—*Abrus precatorius*.

autumn, for the plant is deciduous. It, like all other deciduous plants, must now be allowed a period of rest by withholding water as the foliage decays, yet not permitting the soil to become "dry as dust," which is a cause of injury to many plants during their resting period.

We have known such climbing plants as *Passiflora*, *Clerodendron*, *Clematis*, and *Stephanotis* to have been impaired in vigour by extreme dryness in the resting period. We have even known *Fuchsias*, *Roses*, *Deutzias*, and other leaf-shedding plants to have been dried so extremely in the winter as to almost refuse to break into growth in the spring. We have known also fruit trees and Vines to be greatly injured by the same cause—the former putting forth weak blossoms, and the latter breaking weakly and irregularly. It is sometimes forgotten that plants

THE Council of the Royal Horticultural Society have the pleasure of announcing to the Fellows that they have succeeded in making arrangements with Her Majesty's Commissioners of 1851, whereby the gardens are granted to them virtually rent free, but only upon the performance of one important condition—viz., that the annual income from subscriptions shall be raised to £10,000.

The present income from subscriptions amounts to £7700, a sum which experience has proved to be quite inadequate to maintain the gardens efficiently with regard either to their usefulness or their attractiveness.

The Council have been most desirous that the necessary ad-

dition to their income should be raised without undue interference with the privileges of their Fellows. They have carefully inquired into the causes why the income of the Society has not increased in proportion with the increase in the population, wealth, and importance of the neighbouring districts; and they are satisfied that this is due to the practice of transferring tickets, by which the use of the gardens is to a very large extent enjoyed by those who contribute nothing to its funds, and they are convinced that they cannot expect to obtain that enlarged revenue which is essential to their continued existence without putting an end to this practice.

It is upon this principle that the accompanying summary of the privileges of the Fellows has been framed.

Should the Council be—as they confidently hope they will be—successful in their appeal to existing Fellows and to the residents in the neighbourhood of the gardens, they will soon be in possession of funds which will enable them gradually to discharge the debts which have accrued in past times, greatly to improve the condition of the gardens, and to increase at once their usefulness and their beauty.

But they must not conceal the fact, that if this appeal should prove unsuccessful the failure would be most disastrous both to the interests of horticultural science and to those of the residents of that part of the metropolis who now enjoy the many benefits resulting from the existence of these spacious and beautiful gardens. The project so warmly supported by the late Prince Consort—so hopefully accepted by the public—of bringing home to greater numbers than heretofore the means of studying horticulture, would in that case be abandoned, and it would be for Her Majesty's Commissioners of 1861 to decide to what new and more profitable uses the twenty-two acres now occupied by the South Kensington Horticultural Gardens should be applied.

The Council believe that these calamitous results may be averted by measures which would have the effect of inducing those who now enjoy for themselves and their families most of the advantages of the gardens without paying for them, to contribute a fair and moderate annual sum towards their maintenance; and it is with that view that they have prepared the accompanying regulations, which will come into operation on the 1st January, 1876.

ABERDARE, President.

## ROYAL HORTICULTURAL SOCIETY—FRUIT AND CHRYSANTHEMUM SHOW.

NOVEMBER 10TH.

CHRYSANTHEMUMS being unusually good this year, and fruit unusually plentiful; the conditions of the Show, too, being unusually liberal both in the prompt payment of the prize money and in the facilities offered to the public; confidence also being restored and an union of sympathy established between horticulturists and the "powers that be," it would have been disappointing had not the Exhibition on this occasion been unusual also by its extent and excellence. The arrangement of the schedule was not, perhaps, all that could be desired, seeing that all the fruit classes were "open," and English growers certainly placed at a great disadvantage in being forced into competition with the more highly favoured Channel Islanders, in the classes for Pears for instance; still the proof of the arrangement lays in the results, and these we will so far as time permits proceed to notice. We know, too, that the restored confidence, though prompt, came too late to enable some growers to compete in the Chrysanthemum classes, for they had no time to prepare their plants after the "restoration." But we will not dwell on the past where all worked honestly and with the best motives, but will describe the good results of the present and hope for still greater successes in the future. The early morning of the Show will long be remembered by the competitors by the heavy downpour of rain, but as the morning advanced the clouds became exhausted.

The Exhibition, especially in the fruit classes, is truly a great one, even surpassing the most sanguine expectations. The plants of Chrysanthemums are, perhaps, generally small, but well grown. The out blooms are splendid. Thirty-five fine Pines are exhibited, and the Grapes are an excellent display. It is, however, the Pears and Apples that contribute the great feature of the Show, and assuredly not such a fine exhibition of these fruits have this year been exhibited. The vegetables, especially Potatoes, are also very good, and the miscellaneous groups of plants effective and fine.

For twelve large-flowered Chrysanthemums in pots (open), Mr. Turner, Slough, had plants in 9-inch pots, containing each from twelve to thirty fine blooms, the plants being 4 to 6 feet in height. Mr. G. Rundle, George Glenny, Elaine, Jardin des Plantes being very fine, and the varieties noticed in another column being very good. He had the first prize. In the amateurs' class for six plants there were four competitors. Mr. Hall, gardener to W. Stevens, Esq., Springfield, Tulsa Hill, had plants 8½ feet across and 2 feet high, each having over fifty fine blooms;

the sorts comprised Prince of Wales, Mr. Gladstone, G. Glenny, Lady Harding, Dr. Sharpe, and Mr. J. Rundle. Mr. Herrington, gardener to W. H. Soder, Esq., Clapham Park, had larger plants with better foliage; they were very massive. Mr. Brunlees, Prince of Wales, Lady Haliburton, and Lady Talfourd were very fine. Mr. Fox, gardener to O. Millington, Esq., East Combe, Old Charlton, had standard plants with 4 feet stems and compact heads 2 feet in diameter; small blooms. The prizes were awarded to Mr. Hall, Mr. Herrington, and Mr. Shepherd in the order named.

Twelve Pompons in pots (open).—Mr. Harding, gardener to Rev. W. Arthur, Clapham Common, had nice plants, some pyramidal, and some flat trained; Cedo Nulli and Antonius amongst the former, and Bob and Martha amongst the latter, being the most noticeable. Six Pompons in pots (amateurs).—In this class were five competitors, the plants varying greatly in habit and size. Mr. Fox had nice standard plants, healthy and well bloomed; Mr. Herrington, pyramids; Mr. Shepherd, small and densely-bloomed specimens; and Mr. Whittaker, large flat-trained plants. The prizes were awarded to Mr. Whittaker, Mr. Shepherd, and Mr. Herrington. The Cedo Nulli, Madame Martha, Bob, Brilliant, La Folie, Rose Trevenna, Salmon, and Andromeda were the best varieties in this class.

Single specimen large-flowered Chrysanthemums (nurserymen).—Mr. Turner, Slough, was the only exhibitor, and had the first prize for Mr. George Rundle with thirty perfect blooms, the plant being trained upright and 5 feet in height. (Amateurs).—Four competitors. Mr. Hall was placed first with a fine flat plant of Mr. Brunlees, having sixty blooms. Mr. Herrington had also Mr. Brunlees very fine, and had the second prize; third honours going to Mr. Whittaker, who staged a globular plant of Mrs. Sharpe. (Amateurs).—Three competitors. Mr. Herrington with Golden Cedo Nulli, 4 feet across; Mr. Whittaker, gardener to S. Williams, Esq., The Laurels, Putney, Arabella, 8 feet in diameter; and Mr. Shepherd with a small plant of Cedo Nulli being placed in the order named.

Cut Blooms.—Twenty-four large blooms (nurserymen), Japanese varieties excluded. Mr. Turner was the only exhibitor, and had the first prize with the standard varieties.

Twelve large-flowered Chrysanthemums (amateurs).—In this class were twelve competitors, and many of the blooms were exceedingly fine, others being small and irregular. Mr. O. Waters, gardener to A. Mongredien, Esq., Forest Hill; and Mr. Pearce, gardener to Professor Adams, Cambridge, had the largest blooms; but wonderfully compact examples came from Mr. Hall, gardener to W. Stevens, Esq. Mr. Hillier, 18, Priory Road, Wandsworth Road, and Mr. Smith, British House, Putney Heath, had admirably finished and compact blooms. The sorts comprise the standard varieties mentioned throughout our reports this week. The prizes were awarded to Mr. Waters, Mr. Hillier, and Mr. Smith in the order named.

Twelve Japanese varieties, distinct, open.—Mr. J. Hinnell, gardener to F. A. Davis, Esq., Anglesea House, Surbiton, had no competitors. He had the first prize for The Comet, The Daimio, Elaine, Red Dragon, Apollo, James Salter, The Sultan, Fair Maid of Guernsey, Bronze Dragon, Mrs. Goodlot, and Jane Salter.

Mr. Thomas Hobbs, Lower Eaton, Bristol, exhibited seedling Chrysanthemums from imported seed named Mrs. Naah, like Mr. G. Rundle.

Six Bonvardias (open).—Mr. Turner had the first prize with nice plants in 5-inch pots; the plants were about a foot in diameter, with very healthy foliage and fresh opening trusses. The sorts were Jasmine-flora, Hogarth, and Vreelandii. Second honours going to Mr. Aldous, Gloucester Road, South Kensington, who had less compact plants, but with fine blooms and trusses. Six Tree Carnations.—Mr. Turner, Slough, staged six hardy, healthy, decorative plants, in 5 to 7-inch pots. They were very clean and healthy, with handsome blooms. The sorts were Sir G. Wolseley, Amateur, Lord Dundreary, Herman Stanger, Jessica, and Balacava. They were awarded the first prize. Three pans of Roman Hyacinths, forced, the pans not to exceed 12 inches in diameter.—Mr. J. Aldous, Gloucester Road, South Kensington, was first with pans containing each about fifty spikes, and arranged in a pyramidal form; Mr. S. Lambert, gardener to H. W. Segelcke, Esq., Herne Hill, being placed second with smaller pans more thinly arranged, the spikes having very fine bells.

MISCELLANEOUS.—Messrs. Veitch & Sons' group of Chrysanthemums had remarkably fine blooms, with exuberant foliage; most striking were Grandiflorum, Apollo, The Cossack, and Fair Maid of Guernsey amongst the Japanese varieties. Mr. Turner had also a massive and fine group; he also exhibited his admirable collection of pyramidal Ivies.

Mr. B. S. Williams, Holloway, staged a beautiful group of medium-sized decorative plants comprising Cypripediums, Calanthes, Griffinia Blumenavia, Ferns, Palms, &c. Mr. Aldous also staged an attractive collection of flowering plants and Palms. Mr. H. B. Smith, Ealing, staged a group of Cyclamens, which were very good for the early period. Some of the dark colours

were very rich, and the lights pure. Mr. S. Ford, F.R.H.S., Leonardslee, Horsaam, exhibited a group of *Celosias*, very fine and brilliant in colour.

**PINES.**—Of these there is a noble display. For two Queens Mr. Scammell, gardener to C. Baily, Esq., The Priory, Tunbridge Wells, had the first honours for handsome fruits weighing 10 lbs. 6 oz.; Mr. O. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, being second with plump and well-ripened fruits; Mr. Harris being placed third for thinner fruits not fully ripe. For two Smooth-leaved *Cayennes* Mr. Jones, the Royal Gardens, Frogmore, had the first place with grand examples; Mr. Ward, gardener to T. R. Miller, Esq., Bishop Stortford, being second for fine fruits not fully ripe; and Mr. Rochford, market gardener, Tottenham, third for fine but also unripe fruits. For one fruit, any variety, Mr. Jones had the first award for a grand Smooth *Cayenne*; Mr. Scammell being second with a perfectly-ripened Queen weighing 5 lbs. 6 oz.; and Mr. Miles, gardener to Lord Carington, Wycombe Abbey, third for a handsome *Montserrat*. Mr. Jones also exhibited six splendid fruits of *Smooth Cayenne*.

**GRAPES.**—The exhibition of these is very fine. In Class 2, for three bunches of Black Hamburgs, Mr. Coleman, as usual, has the premier award for compact bunches and even and well-coloured berries; second honours going to Mr. Iggulder, gardener to C. B. Bingley, Esq., Stanhope Park, Greenford, for larger bunches, but not quite perfect in colour. Mr. Allward, gardener to T. G. Barclay, Esq., Lower Woodside, Hatfield, for nice bunches, fine berries, but not quite black, having the third prize.

In Class 19, for two bunches each of not more than ten kinds, Messrs. H. Lane & Sons, Berkhamstead, had the field to themselves, and won the gold medal with *Gros Colman*, *Foster's Seedling*, *Muscat Hamburg*, *Muscat of Alexandria*, *Gros Guillaume*, *Trebbiano*, *Alicante*, Mrs. Pines, and *Lady Downe's Seedling*, very fine in berry and colour. *Gros Colman* was fine in berry but not perfect in colour.

For three bunches of Black *Alicante* Messrs. Lane & Sons, Berkhamstead, had the first place for medium-sized bunches, with good and well-coloured berries; second prize going to Mr. Allward for larger examples; and third to Mr. Wattam, gardener to A. H. Longman, Esq., Shendish Gardens, Hemel Hempstead, also for large bunches. Mr. Munro, Potter's Bar, and Mr. Haycock, Barham Court, had handsome table fruit in this class. Twelve competitors.

For three bunches of any other kind the first prize was awarded to Mr. Wildsmith, gardener to Viscount Eversley, Eokfield Place, for very fine *Gros Colmans*; second honours going to Mr. Kniller, The Gardens, Malshanger Park, for really splendidly finished *Lady Downe's*, Mr. Coleman having the third prize for good examples of the same variety.

For three bunches of *Frontignan* or any other *Muscat-flavoured* round-berried kind Messrs. Lane & Sons had the premier prize for three fine full bunches of *Dr. Hogg*, having plump medium-sized berries.

For three bunches of *Muscat of Alexandria* Mr. Atkinson, Lookinge Gardens, Wantage, had the first place for bunches larger and almost as good in finish and quality as those of Mr. Wattam, who had the second place. Messrs. Lane & Son were placed third for good tapering bunches, but not perfect in colour.

For three bunches of any other white kind Mr. Wattam, gardener to A. H. Longman, Esq., had the first place for excellent examples of *Foster's Seedling*; Mr. Wildsmith being second for large bunches of *Trebbiano*, and Mr. Allward third for *Calabrian Raisin*.

For the heaviest bunch Mr. Wattam had the post of honour with a splendid bunch of *Alicante* weighing 10 lbs., the berries being fine and well coloured. Mr. Bannerman was second with *Gros Guillaume* weighing 7 lbs., Mr. Edwards having the third place with *Gros Guillaume* weighing 6 lbs. 8 oz. A good bunch with fine berries of *Waltham Cross* was exhibited weighing 8 lbs. 10 oz. Mr. Record exhibited fine outdoor *Grapes*, which worthily were awarded a prize.

**APPLES.**—The display here is extraordinarily large and fine. For six varieties of dessert Apples there were about thirty competitors. Mr. Bowles, gardener to W. Skinner, Esq., Maidstone, being first with *Cox's Orange Pippin*, *Count Pendu Plat*, *Warwickshire Pippin*, *King William*, *Ribston Pippin*, and a handsome *Russet* variety; Mr. Arnold, gardener to G. Wood, Esq., Rochford, Essex, being second, *Beauty of Wilts* and *Golden Pearmain* being very handsome; and Mr. Smith, Romford, Essex, third. For three varieties of dessert kind nearly forty competed; Mr. Jones, The Gardens, Elvetham Park, Winchfield, being placed first with *Almond Pippin*, *Ribston Pippin*, and *King of the Pippins*, the second prize going to Mr. Murrell, gardener to A. R. Allerton, Esq., Coleman's Lodge, Prittlewell; and third, Mr. Lumsden, Bloxholm Hall, Sleaford. For six fruit of *Cox's Orange Pippin* thirty-four competed. Mr. Miller, gardener to F. F. Friend, Esq., North Down, Margate, Mr. Holder, Springfield, Maidstone, and Mr. Coles, gardener to

A. Smee, Esq., Bridge, Wallington, being placed in the order named. Of this fine variety Mr. Turner exhibited a box of fruits of splendid colour and quality. For six fruits of *Golden Pippin* Mr. Farrow, gardener to G. Batters, Esq., Enfield, was placed first; Mr. Arnold, Rochford, being second; and Mr. Smith, Romford, Essex, third. Prizes were also offered for *Margil*, *Cockle Pippin*, *Ribston Pippin*, and *Court Pendu Plat*, for all of which there was good competition. The winners will be found in our advertising columns. For six fruit of any other dessert kind Mr. Haycock was placed first with splendid *King of the Pippins*; Mr. Head being second with the same sort, and Mr. Smith, Romford, third for *Cornish Gilliflower*.

For eighteen varieties of kitchen Apples there were twelve competitors, the first prize going to Mr. Ford, Leonardslee, for a grand and even collection; Mr. Haycock, Barham Court, being second; and Mr. Webb, Calcot, third. Nearly all these collections were of very great excellence. For six varieties there was also a grand display by about forty competitors, the first prize being won by Mr. Ford, Wrest Park, for splendid dishes of immense size and finish. Some of the prizes we were unable to ascertain, but they will be found in the official list.

**PEARS.**—In this section the display was remarkable by its extent, and from the immense Jersey specimens, and not less so for the superior examples of English-grown fruit. For eighteen dessert varieties there was good competition; many splendid dishes being exhibited. Mr. Pluck, 88, New Street, Jersey, had the first prize; Mr. Thomas, 23, Burrard Street, Jersey, being placed second; and Mr. Haycock, Barham Court, third. For six varieties there was also great competition, and many splendid dishes staged. Mr. Ford had *Pitmaston Duchess* in splendid condition, and *Beurré Clairgeau* was in grand form. Prizes were also awarded to separate dishes of *Louise Bonne of Jersey*, *Marie Louise*, *Glou Morceau*, *Duchesse d'Angoulême*, *Doyenné du Comice*, *Maréchal de Cour*, *Van Mons Leon Leclerc*, *Catillac*, and *Uvedale's St. Germain*; and many handsome dishes were staged. The awards for these, also for other classes, which we are unable to note in detail, are recorded in the advertised list.

Vegetables were well represented, and the liberal prizes offered by the enterprising firms of James Carter & Co., Holborn, and Sutton & Sons, Reading, brought out some excellent examples of culture creditable alike to growers and seedsmen. The prizes of Messrs. Hooper & Sons were not, we believe, awarded, but several piles of fine tubers were exhibited. Messrs. James Carter & Co. exhibited an imposing collection of sixty varieties of Cabbages and eight sorts of Potatoes. Mr. Ormson's new tubular boiler was exhibited, and attracted considerable notice.

The Exhibition closes this (Thursday) evening, and it is certainly worthy of extensive patronage.

**FRUIT COMMITTEE.**—Henry Webb, Esq., in the chair. A. Rawson, Esq., Bromley Common, sent a seedling Pear, which was too much decayed. Mr. Douglas, Loxford Hall, Essex, sent a seedling Apple of small size, conical shape, and smooth yellow skin, with a tinge of brown on one side. It was of excellent flavour. Mr. Bennett of Babley Gardens sent a seedling Apple somewhat like the *Blenheim Pippin*, which was not considered of sufficient merit to receive a certificate. Fountaine Walker, Esq., Ness Castle, Inverness, sent a fine fruit of *Physianthus albens*, and a vote of thanks was awarded. Sir William Hutt, Appley Towers, Ryde, sent fruit of *Diospyros Kaki*, a Japanese fruit of the size of an Orange, and a fine golden yellow colour. It was awarded a cultural commendation. M. B. Treeve, Esq., 29, Edwards Square, sent a seedling Apple called *Kensington Pippin*, a flattish yellow Apple narrowing to the crown. It was found to be unusually acid. Mr. M. G. Pragnell, Castle Gardens, Sherborne, sent a seedling Apple remarkable for its acidity. Mr. Woodford, Eastwall Park, sent a seedling Apple called *Kate Woodford*, which was not in good condition. Mr. Gilbert, Burghley Gardens, sent a seedling Apple called *Burghley Apple*, which was past its season. Mr. Matthews, Beddington, near Croydon, sent a seedling Apple of good flavour, but not of unusual excellence. Mr. Dancer of Little Sutton sent a fine dish of *Cox's Orange Pippin*, *Huyshe's Prince of Wales*, and *Beurré d'Arenberg*. Mr. Dancer also exhibited fruit of a seedling Pear raised by Mr. Wilmott of Isleworth from *Marie Louise*. It is of enormous size, and has a great deal of the appearance of *Marie Louise*; the flesh was very tender and buttery. Mr. Lock of Red Hill sent a seedling Apple which did not possess any unusual merit. Mr. Charles Turner of Slough sent fruit of *Oswego Beurré*, which was not in condition. The Hon. and Rev. J. T. Boscawen sent a box of *Cornish Gilliflower Apple* in very fine condition, which were much admired for the exceeding richness of flavour. W. E. Essington, Esq., of Bewdley, sent a seedling Pear of excellent flavour, which is somewhat similar to that of *Seckle*. It was much admired, but as all the specimens showed signs of decay at the core the Committee desired to see it another year. Mr. William Paul of Waltham Cross sent six dishes of Pears, including fine specimens of *Doyenné du Comice*, *Beurré Dumas*, and *Kingsessing*, to which a letter of thanks was

awarded. Mr. Gilbert sent specimens of his selected Brussels Sprouts which the Committee considered too large.

**FLORAL COMMITTEE.**—Dr. Kellock in the chair. The Council-room presented a very lively appearance from the fine collection of seedling hybrid *Dracenas* sent by Mr. Wills of the Anerley Road Nursery, Norwood. The plants are exceedingly creditable to the grower, and some of them are very distinct in character.

Messrs. Veitch sent a very fine collection of Orchids, and also a collection of plants, of which every one was a hybrid of their own raising. The collection of hybrids comprised six varieties of *Nepenthes*. The plants were splendidly grown and very distinct in character; they were *N. intermedia*, *N. Cheloni*, *N. Dominii*, *N. hybrida*, *N. hybrida maculata*, and *N. Sedeni*. *Calanthe Veitchii*, one of the most useful of winter-flowering Orchids, was shown in two varieties. There were also five varieties of hybrid *Rhododendrons*; *Princess Alexandra* has white flowers, *Princess Royal* delicate pink, and they contrast well with the brilliantly-coloured flowers of *Queen of Denmark* and *Princess of Wales*. *Dracena hybrida*, a cross between *D. magnifica* and *D. albicans*, has been shown previously, and well maintains its high character. *D. Taylori* was also exhibited; it has bold bronzy metallic foliage, and is very striking. Of hybrid Orchids there were *Cattleya exoniensis*, *C. Dominiana*, *Cypripedium Harrisonianum*, *C. Sedeni*, *C. Dominii*, *C. vexillarium*, *C. Marshallianum*, and *C. Arthurianum*. A fine plant of *Alocaasia Sedeni* completed the collection. This fine collection of plants were awarded the gold medal. Mr. Wills's *Dracenas* are noticed in another column, and to them the gold medal was also awarded.

The collection of Orchids from Messrs. Veitch comprised some fine winter-flowering species; amongst them was a splendid *Cattleya labiata*, the winter-flowering *Calanthes*, *Odontoglossums*, *Pleiones*, *Masdevallias*, &c., crowned with a fine *Vanda suavis*. A vote of thanks was awarded to this collection. Messrs. Veitch also sent *Cupressus Lawsoniana variegata*.

Mr. Charles Turner of Slough sent new perpetual-flowering Carnations. Sir Garnet Wolseley received a first-class certificate; a second-class award being voted to Mrs. Fowler, a fine rose-coloured flower. A beautiful golden sport of Mrs. G. Rundle *Chrysanthemum* was sent by Messrs. S. Dixon of the Amburst Nurseries, Hackney.

Mr. Denning, Londeborough Gardens, received a first-class certificate for *Cattleya Minas*. A cultural certificate was awarded to Mr. Smith, gardener to — Chane, Esq., Henley-on-Thames, for a splendidly-flowered specimen of *Vanda cœrulea*. It had sixty-seven flowers on five spikes.

Mr. R. Dean, Ealing, received a vote of thanks for a collection of *Echeverias*, and to E. rotundifolia a first-class certificate was awarded. Mr. Oroucher, gardener to J. F. Peacock, Esq., Hammersmith, also received a first-class certificate for *Echeveria pachytoides*.

From the nurseries of Messrs. Wm. Paul & Son of Waltham Cross were sent a splendid collection of sprays out from hardy trees and shrubs to illustrate the autumnal tints; many were ornamented with berries. With them was sent a basket of *Euonymus flavescens*, a new golden winter-bedding plant. It is one well adapted for that purpose.

### TOBACCO.

THOUGH *Nicotiana rustica* is indigenous in Western Asia, yet it is considered indisputable that no tobacco was smoked in the Old World before the discovery of the New. It was, therefore, with great astonishment that I read, in a work of Bunsen's, a quotation from the sayings of Buddha, as printed in the Memoirs of the Academy of St. Petersburg, wherein that sage, who lived five centuries before the Christian era, speaks of a man smoking tobacco. As the matter deserved probing, and as the respectability of the source from which the assertion proceeded made the error, if such it were, only the more likely to obtain currency, I wrote to Max Müller, as the best living authority, requesting him to consult the original. He replied, "There is no trace of tobacco in the original, nor even of smoking, but simply of incense."—G. S.

**GRUBS IN CARROT AND ONION BEDS.**—We had an early visit from the grubs this year, and lost thousands of young Onions before they were noticed. As soon as they were seen the beds were covered over nearly half an inch thick with soot, then thoroughly watered, and I have seen no grubs since.—F. S. C. S.

### NOTES AND GLEANINGS.

ONE of the finest specimens of that excellent *PEAR DOYENNE DU COMICE* which we have ever seen has been sent to us by Mr. G. F. Wilson of Heatherbank, Weybridge Heath. It

was 11½ inches in its latitudinal circumference, and exactly a foot in its longitudinal. This was grown on one of Mr. Wilson's orchard-house trees, which during the blooming and setting period are kept in the orchard house, but the fruit was ripened out of doors in the open air. It was most delicious.

—We have received from Mr. George Haskell of Ipswich, Massachusetts, a collection of ten varieties of SEEDLING GRAPES, raised by crossing the native *Vitis riparia* with European varieties, and *vice versa*. These are very curious, and some of them are very excellent varieties. The influence of the cross is very apparent in all of them, and it is quite possible that in this way varieties may be raised that will ripen out of doors in this country. Even in this unfavourable season Admiral Hornby has ripened one of the American Grapes at the Cottage, Knowsley, and Mr. E. J. Beale has been equally successful at Twickenham. One or two varieties which have the Black Hamburg and White Chasselas for their male parents are very good indeed, and have a flavour which is quite peculiar.

—M. EDOUARD MORREN has published the third edition of his "CORRESPONDENCE BOTANIQUE," which is a list of the Botanical Gardens, Professorial Chairs, and Museums throughout the world. It is a valuable and useful aid to botanical correspondence, and is wonderfully correctly and carefully prepared.

—We have received from Messrs. William Maule & Son of Bristol a portion of JAM made from the fruit of *Pyrus Maulei*. We remarked the excellency of this new preserve when we tasted it the first year that the plant was exhibited at the Bath Show. Good as it was then, it is certainly better now, experience in the making of it having perfected the process. It is quite a new flavour, is rich without being cloying, and has a fine, brisk, acidulous smack, which will make it very acceptable for many purposes in domestic confectionery.

—We have the pleasure to announce that Mr. JOHN INGRAM, of the old-established firm of Wood & Ingram, nurserymen, Huntingdon, has been unanimously elected to the office of Mayor of Huntingdon for the coming year.

—AN American paper says—"I do not molest the birds; instead of shooting them or setting up scarecrows to frighten them away, I throw out every possible inducement for them to build their nest in my fruit trees. The birds capture a large share of the insects in the larval state. For the residue of the insects which infest my vegetable garden I find that the laboratory of the chemist furnishes materials fatal to them all, among which materials white hellebore and cayenne pepper are of the most utility; the bug or grub which cannot find vegetation unflavoured with these articles will seek its breakfast elsewhere, and leave my garden unmolested. A few drops of carbolic acid in a pint of water will clean house plants from lice in a very short time. If mosquitoes or other bloodsuckers infest our sleeping rooms at night, we uncork a bottle of the oil of Pennyroyal, and these insects leave in great haste, nor will they return so long as the air in the room is loaded with the fumes of that aromatic herb. If rats enter the cellar, a little powdered potash thrown into their holes, or mixed with meal and scattered in their runs, never fails to drive them away. Cayenne pepper will keep the buttery and storeroom free from ants and cockroaches. If a mouse makes an entrance into any part of your dwelling, saturate a rag with cayenne in solution and stuff it into the hole, which can then be repaired with either wood or mortar. No rat or mouse will eat the rag for the purpose of opening communications with a depot of supplies."

### CULTURE OF PHALÆNOPSIS.

THE culture of Orchids has been very much extended during the last ten years, and their management is more generally understood by gardeners and amateurs, so that these quaint, interesting, and beautiful flowers are to be seen and admired in most gardens, including many of very modest pretensions. Nearly the whole order is amenable to ordinary cultivation. There are, however, a few species, or even an entire genus, that will occasionally baffle the skill of the most ardent cultivators, but unless it is desirable to grow these difficult subjects to complete a selection, or for some other purpose, they are best let alone. There is no need to trouble about them, as there are hundreds of species and varieties of the greatest beauty that can be grown without any difficulty.

The cultivator must first ascertain what are the requirements of his plants, and their wants, which are few and simple, must be attended to at the right time. There are three degrees of temperature in which nearly all Orchids may be grown. The first and most simple is the cool house, in which an extensive and most beautiful section of Orchids may be cultivated. The minimum temperature of this house may be 45°, or it may fall to 40° during the winter months without any injury to the plants. The next is the Cattleya or Brazilian house with a minimum of 50° to 55° during winter; and the East Indian house with a minimum of 65°, or in cold weather 60°. The maximum temperature for the above is 5° to 10° higher.

One of the main elements of success in Orchid culture is the arrangement and efficiency of the ventilation; let the biting east wind blow for a few hours directly on even the hardiest species of the cool-house section, and the chances are that the plant will be utterly ruined. I have seen a *Masdevallia* cut over as if with a knife by the wind blowing directly upon it through a narrow opening. The plants require plenty of fresh air, but the ventilation must be arranged so that the currents of air pass on to the hot-water apparatus before being diffused through the house, and when this is the case air may be admitted every day even during winter; indeed, some of the best cultivators have small openings in the side walls, generally about a foot or 18 inches from the surface of the ground, an and day.

The genus *Phalænopsis* requires a house, and one thing greatly in that the plants occupy a very small space are produced in great abundance are now upwards of a score of genera, a few of them at least hybrids, and here Nature herself of the most experienced cultivator. Some of the most skilful Orchidists the different species of *Phalænopsis* time all their efforts have been worth while to notice all the very rare and likely to be so, nor a sort at all to be compared to common species.

The plant that I would place first, and of this there are several in the size and formation of the lip are purchased that have not Borneo with large leaves and flowers are the largest of all the *Phalænopsis* base or centre of the lip being conspicuously marked with yellow or orange. Next to the above comes the queen of Orchids, *P. amabilis*, from Manilla; the flowers differ from those of *P. grandiflora* in being smaller, and the lip instead of being stained with gold is marked with rose or pink. Next in order of merit is *P. Schilleriana*, another Manilla species. This is very distinct, and has large, handsomely variegated foliage. The leaves are olive green, barred and mottled with creamy white. It is also one of the most free-flowering. The flowers are produced on long branched spikes, as many as a hundred or more flowers having been produced on one spike. This species flowers earlier in the season than the two already named; indeed, all of them have a tendency to throw-up their flower spikes early in the year, but if the spikes of *P. grandiflora* and *P. amabilis* are pinched others will be formed later, and the flowering season is thus retarded.

It will not answer to stop the spikes of *P. Schilleriana*, as, unlike the others, this variety will not form a second spike, and a season would be lost. This would be one of the most selling exhibition plants but for its early-flowering propensity:

it is seldom to be seen in flower after May. The above-named species are by far the best for ordinary cultivators; they are easily grown, and are moderate in price.

A new species was introduced last year which is, no doubt, a natural hybrid between *P. Schilleriana* and *P. amabilis*. As I have seen it, it is certainly inferior to either of its parents. The leaves are slightly barred and mottled, as *P. Schilleriana*, and the flowers are between the two in size and colour. It has been named *P. leucorrhoda*. *P. intermedia* is also said to be a hybrid, and all of them are, no doubt, interesting and very pretty.

The mode of culture pursued by different growers is very

Fig. 92.—*Phalænopsis amabilis*.

different under the same circumstances. To be successful a high temperature must be kept-up, with plenty of atmospheric moisture, which is obtained in winter by sprinkling the paths and stages with water two or three times a-day, and in summer this is supplemented by having troughs filled with water placed over the hot-water pipes. The plants seem to thrive best when they are placed near the glass, and they also grow most freely if planted in baskets. These need not be described here, as a drawing and description of a suitable basket is given at page 339 of the present volume.

The manner of basketing the plants may be briefly described. A few large pots or sherds are placed on the bottom, then some pieces of a smaller size to fill the basket three parts of its depth, the remaining portion being filled-up with live chopped sphagnum and pots or sherds in equal proportions. The roots of the Orchid are just covered, and the plant is put-in in such a way that the leaves hang over the side of the basket. Until the roots make a start water is applied very sparingly,

only just enough being given to keep the sphagnum alive. The leaves during the summer may be lightly dewed over with a fine syringe every morning. When the plant has started into growth water may be freely applied with the syringe, and if the proper temperature has been kept up, and the atmospheric conditions are suitable, both sphagnum and plant will grow freely. The roots twine round and into the basket, and they cannot come into contact with decaying organic matter, which invariably causes decay. The baskets are suspended so that the plants are about 18 inches from the glass, and they also ought to be placed in the most shady part of the house.

Phalænopses cannot bear sunshine. The shading material, which ought to be made to run up and down, must be ready for use from March until the end of October. These plants are also adapted for pot culture; liberal drainage must be used, and the plants ought to be elevated above the rim of the pot. I have seen them do well with a compost of equal parts very fibry peat, sphagnum, and potsherds.—J. DOUGLAS.

### STRAWBERRIES.

I HAVE received to-day (November 6) seven fine and well-crowned plants of *La Constante* and five equally well-crowned plants of *Ne Plus Ultra* from Mr. Lovell, who explains that his plants are struck in June and planted out after the heat of summer is over. His land is evidently of a first-class nature, and I should say that such plants in favourable springs would bear a good crop of Strawberries. His mode of culture is good. I had *La Constante* and *Ne Plus Ultra* (*De Jonghe*) some years ago. The last is a fine cropper, good market sort, fair flavour, and often of conical shape. To the general public I recommend *Lucas* (*De Jonghe*) in preference to *La Constante*. *Lucas* is not, perhaps, quite equal to *La Constante*, but it has these points of superior excellence: it is a quicker rooter, stronger plant, does not suffer under sun, and is larger in the berry. It neither suffers from frost nor sun. *La Constante* is hardy as regards winter, but suffers under hot sun.—W. F. RADCLIFFE.

### CHRYSANTHEMUMS AT CHELSEA AND SLOUGH.

BESIDES the public exhibitions of this important autumn flower which are now being held there are private collections which demand notice by their excellence, and which are worthy of inspection by all who are interested in the cultivation of these plants. Two of these collections, amongst others which we know to be worthy of patronage, are those of Messrs. James Veitch & Sons, the Royal Nurseries, Chelsea, and Mr. Charles Turner, the Royal Nurseries, Slough. We first visited, therefore will first notice, the display of Messrs. VEITCH AND SONS. These consist of nearly 500 plants arranged in a spacious span-roofed house; and we know not which to admire most, the sturdy vigour of the plants with foliage fresh down to the pots, or their noble blooms. The plants are in 10 to 12-inch pots, grown on single stems, each plant having three to six flowers which are just approaching perfection, and which will be in good condition for the next ten days. We note a few of the best and which may be considered as standard varieties—those that are uniformly good, and which may be grown with confidence as possessing sterling merit.

White Globe and Empress of India are splendid, the blooms being of unusual depth and substance, and there are immense blooms of Alfred Salter, Prince of Wales, and Beethoven, Fingal has perhaps never been finer, and Bronze and Yellow Jardin des Plantes are remarkably effective. Mr. George Rundle and its fine sulphur-coloured sport George Glenny are, if not the largest, two of the most perfect and constant varieties, and which are very finely finished. The Beverleys—yellow and white—Pink Perfection, White Venus, Guernsey Nugget, Nil Desperandum, Gloria Mundi, are also very fine; and equally good but smaller are Aurea Multiflora, Duke of Roxburgh, John Salter, and Abbé Passaglio.

Some of the Japanese varieties are also particularly gay. Elaine, however, is fading, but its place as a white is well filled by Fair Maid of Guernsey, which is fully as long in the petals, although somewhat looser than the above-named variety. Cry-Kung, bright mauve, is very attractive, as also is Red Dragon. Gold Thread, the new Japanese sort, is not yet expanded, but The Cassack is very gay in its garb of crimson scarlet.

There are also several nice standard plants of Pompons, one of which, Acme of Perfection, is as perfect in the blooms as

it is chaste in colour. As a variety for affording out bloom it is invaluable, while it is equally suitable as a decorative plant. The blooms are exceedingly double, and each petal of rosy pink is margined with white. Altogether the collection is very good, the plants being stout and short-jointed, and the foliage to the eye of the practical grower is as attractive as the bloom.

Besides the Chrysanthemums several beautiful Orchids are in bloom, as Vandas, Cattleyas, Pleiones, Calanthes, &c., and these with other collections of ornamental plants, and the perfect order and cleanliness which pervades the establishment, renders a visit "to Veitch's" at the present time particularly enjoyable.

Very different in character but not less imposing, is the collection of Mr. TURNER at Slough. The display here occupies a house 100 feet in length and 12 in width, which is filled to repletion by all the best varieties. These plants are not grown specially to bring out the individual size of the blooms by limiting their number to two or three on a plant, but some of the plants have each over twenty flowers; and these, considering their numbers and the smallness of the pots employed, are evidence of superior skill in culture, and are splendid examples of decorative plants where numbers are combined with quality.

Mr. George Rundle and George Glenny are here in grand form, and Nil Desperandum for size and symmetry would be difficult to excel. Elaine by its flowing fleecy purity is most attractive, and such plants as are grown here would be a great acquisition to any conservatory. In striking contrast to the whites mentioned is Dr. Sharpe, maroon, and not less effective are the bright crimson masses of Julie Lagraviers, which, although the flowers are flat and small, is yet one of the most useful sorts, by its high colour and free-flowering properties affording a fine supply of out blooms. Bifeman, St. Patrick, Prince Alfred, and Empress of India have perfected noble blooms, and the other standard sorts enumerated above are in admirable condition.

A striking feature in this collection is the smallness of the pots in which most of the plants are grown. Many plants there are containing half a dozen blooms, full, deep, and perfect, which are grown in 6 or 7-inch pots; and how handy and useful such plants are all know whose duty it is to provide ornamental groups for conservatory and other purposes of decoration. By rich feeding and unremitting attention to watering Mr. Turner has well shown the resources of the Chrysanthemum, and has evidently succeeded in obtaining a maximum amount of beauty out of a minimum bulk of soil. The collection is highly worthy of inspection, as are other specialities of this nursery.

The Carnations, of course, are not in bloom, but what a forest of fine layers are now being potted! This work alone will occupy some weeks. Surely there must (as there should) be an increasing demand for these beautiful florists' flowers, and evidently their constant patron is determined to keep pace with it. It is now tree, shrub, and Rose time here, but it would be superfluous to detail the condition of the stock; but it is impossible to pass by unnoticed the fine breadth of the Caucasian Laurel (*Cerasus caucasica*). It is richer, denser, deeper, and hardier than the common Laurel, and must shortly supersede it in all shrubbery plantations. To denote the general condition of the nursery would be to repeat the "old, old story;" it can be summed-up in one word—"Turner's."

A notice of the display at the Pine Apple Place Nursery is postponed until next week.

### A POTATO GRAFTED WITH THE NIGHTSHADE.

A VERY interesting experiment has been made by Mr. Alex. Maule of Bristol, for the purpose of ascertaining what effect a transfusion of the essence of the native *Solanum nigrum* into the constitution of the Potato by grafting would have in preventing the Potato disease. The common Nightshade, it is well known, resists the disease. Mr. Maule conceived that by getting the foliage of the European plant on the Potato that the latter would escape the disease, and he found by experiment his expectation realised. He grafted the one on the other, and the result is before us in an excellent photograph which shows the perfect union of the two species, and the stock plant furnished with a large tuber.

Now Mr. Maule does not intend from this experiment that the whole Potato crop is to be grafted in this fashion. His experiment was intended merely as a test to solve a theory

which was floating in his own mind, and it was a successful one. But it may be pushed a little farther than Mr. Maule has carried it. We all know that in many instances the scion influences the stock as greatly as the stock does the scion; and we see no reason why there may not be a graft-hybrid produced in this case as in many others which would have the power of resisting the disease. The transfusion of the essences of distinct plants is not conveyed exclusively by the pollen grains; and we believe it quite possible, by frequent repetition of the grafting experiment, to change in some important respect the constitution of the cultivated Potato so as to render it more disease-resisting.

It will be very interesting to know what the result of this experiment of Mr. Maule's turns out. We hope Mr. Maule has preserved the tuber with the intention of planting it next season. It would be well to cut it into sets and graft some of the plants produced from these with *Solanum nigrum*, leaving others in their normal condition.

### OPEN STANDARD OR BUSH PEACH AND NECTARINE TREES.

ALLUSION having been made to the growing of Peaches and Nectarines on open standard, or rather bush trees, and cases mentioned where fruit has ripened during the past season on such trees, it would be well to take a retrospect of the past and ascertain what has been attempted in this way in years gone by, and we may possibly be able to form a tolerable correct judgment of what is likely to be accomplished in the future.

Fine warm summers, which now and then occur, favouring the growth and maturing the fruit of many things that do not generally approach that condition in ordinary years, usually tempt the inexperienced into the belief that because they have ripened Grapes against a wall and Peaches on open standards these fruit can always be done so. This is a mistake. These fruits require more sun than the average temperature which our summers afford, and it is only on those very warm seasons that they really ripen well, and it is questionable if they are in reality as likely to do so in a general way as they were a century or more ago. An occasional hot summer or two following each other may be adduced as evidence against this; but two or three years is not sufficient to found a conclusion upon. I well remember the dry sunny seasons of 1857, 1858, and 1859, the last two especially being thought half-tropical, and it was imagined that many fruits and plants would flourish in the open air that are but rarely met with under that mode of culture. Pine Apples were tried in more places than one and reported favourably of, and some sanguine spirits went the length of asserting that England might be independent of foreign countries in the matter of the port and sherry consumed; while Sorghum and other half-tropical green foods were to take the place of those in common use amongst farmers, and certainly some very fine growths of the latter plant in the summer of 1859 did promise well of it; but, alas! the cold wet season of 1860 set aside all expectation of this and other plants becoming generally useful, and the ripening of Peaches and Grapes was out of the question altogether. For some years after this ungenial summer it was urged that Peaches could not be depended on anywhere except under glass, and an impetus was given to the erection of orchard houses, and we have since heard but little of standard trees of the kinds named until the present fine autumn has in a measure revived the subject again by some fairly good fruit having been produced on such trees in favourable situations. Although the cultivation of the Peach as an open standard tree has been recommended I would hardly advise anyone planting a whole orchard of such trees, for the seasons in which they succeed will come so seldom that I fear the disappointments would far exceed the successes.

I think it was about 1858 or 1859 that Mr. Ilman, a nurseryman at Strood near Rochester, ripened Peaches and Nectarines on open standards in his nursery, and pyramid Peach trees for gardens as well as for lawns were strongly recommended at that time. In the latter position they were expected to be equally ornamental in spring while in flower, as they would be useful later on when ripe fruit greeted the eyes of the owner or visitor. But somehow they have never become popular, and I believe what few were planted have produced but little fruit, and have fallen short of the ornamental character expected of them, the growth being irregular and at times ram-

phant, while the difficulties in protecting the fruit blossom from the spring frosts was so great that comparatively little reached the ripening period, and that little has been small and undersized; that there is certainly but slight encouragement to embark extensively in planting many trees of the character named, although by way of experiment, and in a favourable site, the practice is worth trying on a limited scale.

While on this subject I may ask, What success has attended the cultivation of two other fruits of different habits, but each requiring something different to the treatment given to our ordinary hardy fruits—namely, Figs and Apricots? Many years ago—I think it was about 1856—I planted several young Apricot trees in what I thought was a favourable situation, and they grew and flowered very fairly, but I never obtained much fruit from them. About that same period I ceased pruning or doing anything but now and then fastening up a large limb against the wall of two large Fig trees, and they now straggle across the border, and in favourable years produce good fruit; that near the ground on the branches resting upon it being as good as on the top of the trees. I should be glad if those who have been successful in the growth of these two fruits to be good enough to give us the particulars of their practice, more especially if they have succeeded in perfecting them without the aid of walls.—J. BOBSON.

### THE POMEGRANATE OUT OF DOORS.

In an interesting article on the above in your issue for October 14th, page 388, it is stated that this plant does not produce fruit in this country. Perhaps, therefore, it may interest you as well as others to know that a plant of the *Punica granatum* bears fruit annually here, which in some favourable seasons fairly ripens.

I have forwarded you some specimens of this season's growth, but I would mention that those sent are not nearly so ripe as we usually have them, in fact all the fruit that is on the plant has set since the third week in August; neither has the fruit been so plentiful nor the flowers so abundant as in former years, which can be accounted for by the excessive fall of rain we have experienced here this season. The growth of this plant, or what I will term the breastwood, in ordinary seasons is from 9 inches to a foot in length, whereas this season it is more than double that length, and much stronger than usual.

The plant in question is growing against the kitchen wall, which has a south-west aspect, and is well sheltered. The soil is a light sandy loam, which no doubt is greatly impoverished by its close proximity to some large Hollies and other shrubs. The subsoil is sand. It has grown to the height of 52 feet, and covers the wall 24 feet in width. On the highest part the largest quantity of flowers are produced, and only at the extreme points fruit is perfected.

This plant fully corroborates all that you have stated as to its requirements, which are a warm sheltered site, with a poor light well-drained soil.

At a short distance the Pomegranate has the appearance of a Myrtle, and I have heard many a visitor at first sight exclaim, "What an immense Myrtle you have here!" Such was the exclamation of one lady in particular last season; when a second rejoined, "Its great size is not its only novelty, as it actually bears scarlet flowers and fruit."—THOMAS FOOTE, Gardener to Sir Arthur Elton, Bt., Clevedon Court, Somerset.

[The specimens sent were small, but one was nearly ripe.—EDS.]

### HARTHAM PARK,

THE RESIDENCE OF WILLIAM HENRY POYNTER, ESQ.

If we pursue the Bath road for about three miles west of Chippenham it brings us into the parish of Corsham, a wide-extending parish embracing many hamlets, one of which all must pass through on their way to Bath—viz., Pickwick. I notice this to correct a very general but erroneous impression that Charles Dickens took the name of the hero of his first important work from this place. The tale goes that putting his head out of the window of the coach on his way to Bath he asked what was the name of this place, and received for answer "Pickwick," and that the jingling rhyme of the word caught his ear. This, however, is only a case of "as the story goes." The truth, according to Mr. Foster, is that Dickens saw in Pileadilly the Bath coach with the name of "Pickwick, proprietor," upon it, and that the name hit his fancy. Indeed, though Dickens visited Bath in later years almost annu-

ally to see Landor, he had, it is believed, never been in Bath until after he wrote *Pickwick*, and that the scene in that work descriptive of characters in the Assembly Rooms owed its origin not to personal experience, but to the force of imagination, which gathered the materials out of common rumour. But on the Bath road lies *Pickwick*.

Close by, turning off to the right, is Hartham Park, in the county of Wilts, owned by William Henry Poynder, Esq., Lord of the Manor of Hilmonton in the same county, one of a family long known and respected in North Wilts for their untiring efforts in doing good, and for munificence to the poor and needing. Some gentlemen of high position and wealth are respected—this is much; but there are a select few who attain to something higher—viz., who are loved as well as respected, and such is the most enviable position of the squire of Hartham.

The Hartham Park estate has passed through many hands,

as is the case with most properties. Hartham is mentioned in Domesday Book six times under the name of "Heartham." In about A.D. 1400 it belonged to Henry de Hartham; in 1640 it passed to the well-known Wiltshire families of Goddard and Duckett. The former owned the present Hartham Park and Rudlow, and their house stood on the site of the ~~present~~ mansion. The residence of the Ducketts, which stood near, close to the present stables of Hartham Park, was taken down some years ago. Lady James, widow of a Sir William James, a director of the E. I. Company, built the present mansion—that is, the older part. Hartham was purchased by the first Lord Methven, but sold afterwards to the late Mr. Thomas Poynder, who built so largely, making such considerable additions in 1860, that from simply a country gentleman's residence Hartham Park became a large and imposing-looking mansion. The interior contains pictures of great value, and the library is rich in rare copies of works splendidly bound.

Fig. 9A.—HARTHAM PARK—WEST-RED VIEW OF THE MANSION.

Hartham is somewhat connected with English literature. Thus, the Lady James mentioned was a friend and correspondent of Laurence Sterne; and Edmund Smith, a friend of Steele and Addison, author of "*Phædria and Hippolytus*," and translator of "*Longinus on the Sublime*," died at Hartham in 1709. The father of Lord Broughton, Sir Benjamin Hobhouse, lived at Hartham House. The readers of Lord Byron's works will remember Lord Broughton, then Sir John Cam Hobhouse, as a friend of the poet's. That amusing gossip, John Aubrey, has a word to say about Hartham, for he thus writes:—"It is said that the conigre (rabbit warren) here turns the breed of black conies white, and its pasture grounds make the breed of black cattle pied;" but he shrewdly adds, "Let him that knows this believe it," but goes on to say, "The rest of the country hereabouts is much inclined to pied cattle, but commonly the colour is black, or browne, or deepe red. The men and women strong, and something warme and well coloured, a drawing speech something heavy and melancholy, as under Saturn."

One fine afternoon this autumn found me on my way to Hartham Park. Leaving Corham Court on the left I soon turn to the right, and pass near to Hartham Episcopal Chapel, built by the late Mr. Thomas Poynder for the place of worship of his family and dependents, and the inhabitants near. This was a kind act, as Corham parish church lies too far off to benefit the aged and infirm. Oh, would that other large

owners would do the like! Entering the park gates and following the course of a well-planned meandering approach I am soon at the east or front entrance of the house, wondrously enlarged and improved since I knew it first. The view from the front door is somewhat blocked by a clump which was planted to screen the house from the road, and which has now grown over-large. This could easily be remedied, as a much lower screen would keep the road from view, and the noble Elms around would stand out in their full beauty. The Elm is well called by John Evelyn "the Wiltshire weed."

The head gardener, Mr. Thomas Carter, formerly under Mr. Fleming at Trentham, is at hand to show me, by Mr. Poynder's kind permission, everything that is to be seen. We pass to the flower garden on the south side of the house, a plan of which is engraved. This garden is somewhat sunk, and wisely, to avoid the strong westerly gales, and is overlooked by the drawing-room and library windows. The plan of the garden suits the house, and the planting shows Mr. Carter's good taste. Passing along this garden I ascend by steps to the terrace garden, a garden wholly on grass, from which the beds below tall wall. Ascending some more steps I come to the top lawn, a spacious smooth-shaven turf, out of which rise well-kept trees and shrubs. Two splendid Cedars of Lebanon cast their deep layers of shade around, making a fine contrast to the light and graceful Tulip Trees near, and with the hand-

some Horse Chestnuts grown naturally—that is, with their lower branches touching and lying on the grass. Those who only see these trees as usually grown can have no idea of the added beauty when the lowest boughs are as these are.

Besides the trees and shrubs on this extensive top lawn there is one object of particular interest, a copy of the famous Warwick vase cut in one solid piece of Box stone, which when hewn was over 10 tons in weight. This is unfortunately placed too much on one side; whereas, did it stand just in the middle where is now an old Ash it would overlook the two lower gardens, and would form a fine object to look up to, and serve as a connecting link to the eye with the house.

Passing, or rather strolling, along this fine lawn I come to the Beech walk, a very dangerous place indeed for young people to enter, being highly suggestive of engaged rings. Not far off is one of several summer houses, but this one I notice is on an artificial mound, placed there for the view. Where

stands the mound was a pit, which the late Mr. Poynder had filled up and the summer house put on its apex. I thought what a good thing such alterations are for the poor, as bringing to them many days of labour and labour's recompense—wages. How much good people of fortune often do by alterations, which give employment! how much more good is done in this way to the poor than by almsgiving! I now take my leave of the pleasure grounds, just observing in passing that as the finely-undulating and beautifully-wooded park is only separated from these by an iron paling, the idea of space is given, and all cramping quite avoided.

Next comes the kitchen garden, in which, in itself, is nothing remarkable, but in it stands the conservatory, which with the fernery is 70 feet long and 28 feet wide, and the height of the lantern 24 feet. The stove, conservatory, and fernery (one building) is in three compartments. This structure is very elegant. Up its slender pillars run various bright-coloured

Fig. 94.—FLOWER GARDEN AT HARTHAM PARK.

1. Blue Lobelia, edged with Mrs. Pollock.
2. Pelargonium Stella, edged with Golden Chain.
3. Pelargonium Tom Thomb, edged with Silver Chain.
4. Pelargonium Christina, edged with Silver Chain.
5. Alternanthera, edged with Golden Pyrethrum.

6. Centre Iresine, with white and purple Verbena, edged with Mesembryanthemum.
7. Pelargonium Rollison's Unique, edged with Golden Pyrethrum.
8. Grass. Centre vase.

creepers, and crossing high up from pillar to pillar they hang in festoons. Tacsonia Van-Volkemi was there in its beauty, and the Lapageria rosea with its gorgeous bells. There, too, were Bignonias and the Allamanda cathartica with its striking yellow flowers. The centre compartment is the conservatory, the other compartment the fernery. There was the Thunbergia Harriadi; the Golden Fern in its gorgeousness, with Adiantum Farleyense, and many others of magnificent growth. In this stove conservatory and fernery what particularly struck me was the healthiness of every plant and the admirable way in which all were kept. In the stove division I noticed a fine plant of Hibiscus splendens with its intense carmine-scarlet centre.

Next in order come the vineries. The length of the large vinery is 80 feet, its width 21 feet. The height of the back wall is 28 feet, with a half-lantern top. This is a grand vinery, and it was a pleasing thought to know that not only on its hospitable owner's table its beautiful Grapes appeared, but they reached many a poor invalid's lips, and their grateful moisture comforted those almost past earthly comfort. The vinery is in four compartments. The first contains Pope's Hamburg, Lady Downe's Seedling, and that troublesome Grape to grow in many soils, Mrs. Pinee. In the second compartment I found Muscats of Alexandria with splendid berries. This house is heated by six rows of 4-inch pipes. In the

third division again Muscat of Alexandria, in the fourth the Muscat Hamburg and Black Hamburg. Besides this large vinery is a small one 37 feet long, half-span roof, with eight rows of pipes. I saw, too, another kitchen garden chiefly devoted to fruit of about an acre in extent, with its Pear crop a sight to see.

I next come to a very noteworthy part of Hartham Park gardens—viz., the frames, with offices and sheds around it. I remember looking once through the house of a gentleman famous for giving good dinners, and being struck with the exceeding smallness and inconvenience of the kitchen and adjoining offices. I remarked upon this, and pitied the cook. So also in visiting some extensive and well-kept gardens I have often noticed that the offices for the gardener's use—tool houses, potting sheds, &c.—were like the small kitchen for the cook, and I pity the gardener. This, however, is not the case at Hartham Park, but quite the contrary. The gardeners' kitchens, so to speak, are on a grand scale. Imagine half an acre and more of an oblong form, with the centre made into a cold-frame yard, with offices, sheds, &c., on one side and end, the other side and end devoted to wall fruit and houses. Here I found half-span houses over 100 feet in length, divided into four compartments. First is the winter forcing house, second is devoted to Pines and Cucumbers, third to Cucumbers, fourth to greenhouse plants. Next is a Peach house 37 feet long, half-

span. The patent heating apparatus in this yard was the work of Messrs. Cubitt. The quarter of an acre of frames in the centre before mentioned are as to material of good workmanship, the wall plates of teak with galvanised sashes. The frames, as to use, can hardly be over-estimated. What grand feeders to a conservatory! What salads! What bedding stuff! What winter stuff! What Melons! What Strawberries! Why, the open storing shed at the end of the yard is about 80 feet long, in which everything not wanted can be placed at once; not a wheelbarrow need be left out in the wet, nor a disused frame left about looking untidy. Indeed, this yard and its buildings around would gladden any gardener's heart. On the side where the buildings are I find the Mushroom house, slate fronts on cast-iron pillars, and the bottom perforated tiles. I enter the boiler house, and Mr. Carter tells me that Cubitt's patent boilers answer perfectly, heating some thousands of feet of pipes. In the tool house I find perfect order. A notice is printed up, "A place for everything, and everything in its place," and that notice was evidently obeyed in letter and spirit. The potting shed was large enough for a school-room, and the arrangements of the fruit room seemed good, and the fruit in excellent condition. So of the seed room. Lastly, I peep into a second boiler house. The range of offices above described are, as to length, about 210 feet. Such is the frameyard and the buildings around. Instead of everything being old-fashioned and in a half-ruinous state, here was everything new, good, and built on the best principles, and reflecting great credit upon the architect, Mr. Hardwick. Mr. Carter tells me he has been at Hartham about ten years, and that he works with a staff of eight men under him. He has evidently his heart in his calling, and well knows what to do and how to have it done.

Having taken a general glance round I now turn my pony's head towards the Bath approach, and proceed onwards towards the entrance known as Budlow Gate. As I drive on for probably a couple of miles in the park I have a fine view of its undulations and timber, while far away the eye takes in a grand landscape, with what painters so much love, a telling middle distance, the country towards North Wraxall and Colerne standing out in bold relief.

Such is but a slight sketch of Hartham and its surroundings, and I will take leave to add a sincere hope that its kind and generous resident, who has become its possessor but recently, may be spared many years of health and happiness.—WILTSHIRE RECTOR.

### FROST IN LINCOLNSHIRE—WORMS IN FLOWER POTS.

THE remarks of "J. H." headed "Frost in Aberdeenshire" attracted my attention and caused me to refer to my weather diary, and strange to say the reading of the thermometer here on the 11th and 12th of October tallied exactly with the statement given by "J. H." (see page 877)—viz., 6° and 7° of frost. French Beans and Scarlet Runners were killed, and Dahlias and other tender plants partially destroyed.

Respecting soot for preventing worms entering flower pots, I can corroborate all Mr. Douglas has said on that point, as we have frequently used it for the same purpose with good results.—G. R. ALLIS.

### VINES AT OSMASTON MANOR.

YOUR correspondent "J. W." has either been wrongly informed or he is under a false impression with regard to the supply of Grapes and the uses to which the vinerias at Osmaston Manor were put in former years. Having known the place intimately from early in the year 1853 to the end of 1872, and, moreover, having had the management of it for ten years down to the latter date, I am in a position to speak of what was done during that time, and I emphatically deny that the Vines were grown only, or principally, to afford shade for the specimen Orchids. The primary use of the vinerias was to grow Grapes; and although from their peculiar proportions and construction those vinerias were difficult to manage, yet I can say without hesitation that the table of the late proprietor was invariably well supplied with Grapes seven months in the year, which was about as long as the supply would last, the demand being heavy and constant; and in my time I have cut scores of bunches of well-finished Hamburgs weighing from 2 lbs. to 4 lbs. 13 ozs., as well as smaller bunches.

Whether the late owner thought most of his Vines or his

plants would, perhaps, be a difficult point to decide now, but I know that he was as particular and as critical about his Grapes as he was about his plants or anything else; and the only specimen Orchid that was a permanent occupant of a vinery was a large plant of *Dendrobium speciosum*, which was too big to be conveniently moved in and out at the doorway. A few other Orchids were occasionally taken into one of the vinerias to rest when the Vines were in a dormant state—a practice which is far from uncommon. A number of Camellias and Azaleas also were grown under the Vines when the conditions of the vinerias were favourable to the growth of such plants; but this again is, I fancy, a common practice enough, and I repeat that the vinerias were used mainly and successfully for the growth of Grapes.—F. HARRISON, *Knowsley Gardens, Prescot.*

[We have submitted Mr. Harrison's letter to our correspondent, and he replies—"I have been both 'wrongly informed' and also under a 'false impression.' My information was from a gentleman whom I had reason to believe had knowledge of the matter, and not from any servant of the family. I bow, however, to Mr. Harrison's correction. My impression was formed on the structure of the houses and on the appearance of the Vines. Mr. Harrison supports me in the reasonableness of my assumption by admitting the houses to be 'peculiar' and 'difficult to manage.' As to the Vines, without disputing Mr. Harrison's statement, I can only say that they have worn out quickly."]

### ROSES FOR SMALL COLLECTIONS.

THE majority of Rose lovers being small growers, I am sure a word of warning just now at the buying season of the year will not be out of place.

Old growers will bear me out when I say that most new Roses are large, coarse, and without scent, and, moreover, do not last. For example, Mons. Noman as shown at the Crystal Palace some three or four years ago was splendid and unequalled as a light Rose, but it has never been good since its first appearance. This should act as a warning to amateurs not to buy untried sorts. The bulk of new Roses are not improvements. Raisers have yet to excel those three fine old purples Pierre Notting, Vicomte Vigier, and François Louvat, and yet in small gardens one seldom finds them. Why is this? Simply because buyers will buy Roses puffed by raisers instead of waiting and seeing them proved. I would say to small gardeners, Do not have a bad Rose in the place. Instead of buying, say, a hundred sorts, thirty of which are bad, order two or three of a sort. Big print, heavy charges, and vivid descriptions do not make good Roses.

The following may be added to the list I sent you a few weeks back, all being good:—Mdlle. Marie Finger, a darker, and Capitaine Christy, a lighter Mdlle. E. Verdier; Maxime de la Rocheterie, a fine dark purplish red; Comte de Serenye, a fine light blush; Hippolyte Jamin, an improved Countess of Oxford; and Madame V. Verdier left out in error.—AN OLD ROSE-GROWER.

### DR. PLANT.

THREE has just passed away at the ripe age of eighty-seven one of the most accomplished florists it has ever been my good fortune to know. It is a very long time since my love for florists' flowers was first developed, but even then, forty years ago, Dr. Plant was the leading florist in Ireland, and some of his achievements I have never seen excelled, or indeed equalled, in this country. We were some five or six years afterwards thrown together as competitors, and it was a white day in my floricultural calendar when I was enabled to beat "the doctor" in Auriculas. I never did it but once, but to do it once was something. At the period to which I allude Dr. Plant's cultures were the Carnation and Picotee, and the Auricula; he afterwards added the Tulip, and in later years (when it became so great a favourite) the Rose. One characteristic of his cultivation was that he managed plants which nobody else seemed to be able to do. I have never seen, for instance, amongst Auricula-growers such plants of Booth's Freedom as he used to grow and exhibit. I have seen it, and that not one plant only, but many, with six and seven pipes, each pip as large as a half-crown and without the slightest coarseness. Taylor's Glory, Page's Champion, and Hey's Apollo I have seen with him by the dozen. The latter flower, a very beautiful blue self, I have never seen elsewhere; with him it was a most effective flower.

His was the first place I ever saw a stage of blooms in a regular Auricula house, and I shall as long as memory lasts never forget the sight—all the plants models of growth, strong, but not "lissy," and with fine trusses of bloom of generally seven pipes; he never allowed more. He was most chary of introducing novelties, thinking the old better; but although he clung to them he was in later years obliged to confess that in such kinds as George Lightbody, Richard Heady, and others the old had been distanced; and when he introduced a new variety into his frames he very soon obtained a good stock of it. It was the same thing with Carnations. That wondrous rose flake, Burt's Flora's Garland, I have seen with him as one of the grandest flowers possible, but it has now almost passed away, and in very few (if any) lists is it now to be seen.

Of his Tulips it is impossible to speak too highly; they were all of grand strains, of great purity and size; and as he was a true florist he admitted nothing inferior into his collection; and although my memory goes back to Groom's grand collection at Clapham, and I have seen the Slough, Stapleford, and other beds in bloom, I have never seen beds of greater excellence than his were.

As I left Ireland nearly thirty years ago I have had of late years but few opportunities of seeing Dr. Plant and his collections, but I am sure he will be greatly missed in the horticultural world, especially in the Royal Horticultural Society of Ireland, of which he was the oldest member at the time of his death, having joined it forty-five years ago. I fear he leaves but few behind him to follow in his steps, and I am quite sure not one who can occupy the position he for so many years held.—D., Deal.

#### NEW DRACÆNAS AT THE ANERLEY PARK NURSERY.

Mr. WILLS is to be congratulated on the possession of a batch of seedling Dracænas which not only eclipse the few hybrids hitherto raised, but which effectually supersede all foreign introductions of this fine genus of stove plants. For these plants he is indebted to the skill and perseverance of his industrious foreman, the eminent hybridist, Mr. F. Bause. For this splendid achievement Mr. Bause is to be complimented by the whole nation of horticulturists, as he must be honoured and recompensed for his brilliant success. Only a few years ago Mr. Bause revolutionised the family of Coleuses, and unfolded new beauties which were not before dreamt of, and now he has revolutionised the Dracænas, and, as with the touch of the magician, he has brought out the hidden beauties of a family of infinitely greater value than the Coleuses. In three years the Coleuses by rapid propagation had become common; but in three times three years these fine Dracænas will be coveted by those who do not own them, and cherished by those who do.

A portion of these grand hybrids were exhibited yesterday in the Council-room of the Royal Horticultural Society, and it is gratifying to be the first to publish their names and give some description of them. We have also seen them at home, for on the invitation of Mr. Bause we hastened to Anerley to see his brilliant family, and we were fairly startled by their beauty, variety, and distinctness.

The vigour of these plants is wonderful, their habits excellent, and their colours such as have never been seen before in the family. The varieties where white predominates are not only pure and pearly, but the white is a solid white without any flimsy decaying edge. The magenta in their foliage are rich and glowing, the red full and deep, the pink and rose pure and decided, and there are tints of orange, salmon, and purple, with various shades of green and bronze as their staple or ground colours. Yet they are now only just breaking into beauty and character, each new leaf being brighter than the last; and what the plants must be when the tops are struck, and with, as we may reasonably expect, their colours intensified and preserved in the lower leaves, time can only tell. But if never more beautiful than now they are the most beautiful of all, and we take them and briefly describe them as they are.

The quickness with which these plants have been raised and grown is not much less remarkable than their intrinsic merit. Three years have not yet elapsed since Mr. Bause entered the service of Mr. Wills, and here are plants—hundreds of them, of great substance and vigour of from 2 to 3 feet in height. Mr. Bause found a few old stumps showing flower-spikes, and these were the parentage of this unequalled group. The seed was sown on August the 1st, 1874, and on November the 10th,

1875, these splendidly-grown plants were exhibited. Mr. Bause is therefore not only a hybridist of the first rank, but as a cultivator his skill must be equally acknowledged.

The group must be divided into three sections—broad, medium, and small-leaved. The former will be unrivalled for general decorative purposes, and the latter must have the front rank as dinner-table plants. We are able to give the names of about thirty-six varieties which have been selected out of a collection of 1700 seedlings, with their parentage; of the latter the variety first named having been the seed-bearing parent.

*Willisii* × *excelsa* and *Regina*.—Plant robust; leaves broadly oblong and gently curving; colour rich bronze flaked with magenta, some of them suffused with pink. Splendid.

*Bauseii* × *Chelsoni* and *Regina*.—Plant stout and vigorous; foliage broad, of great substance, and arched; colour deep bronze, distinctly edged with deep red, which is pure and constant. A grand variety.

*Victoria* × *concinnum* and *Regina*.—Plant strong, of sub-erect habit; leaves broadly oblong, tapering; colour, lower leaves green and the upper leaves almost pure ivory white, healthy, and with no signs of decay. Very effective.

*Anerleyensis* × *terminalis* and *Regina*.—Plant very robust; leaves long, broad, and sub-pendant; colour bronzy green, creamy, striped with deeper cream and suffused with rose. A bold and attractive variety.

*Versicolor*.—Parentage and character similar to the above, yet distinct. Plant not so robust, but colour richer. Effective.

*Fulgens* × *excelsa* and *terminalis*.—Plant massive; leaves broad and drooping; colour deep bronze with narrow rosy pink margin. Very fine and promising.

*Alba marginata* × *nigrescens* and *Regina*.—Plant robust, erect; leaves green marked with clear white. Distinct and good.

*Mastervii* × *nigrescens* and *Regina*.—Plant massive, dwarf; leaves very broad and drooping; colour light bronze with deep pink edge and a narrow dark midrib; habit very fine. A very promising variety.

*Tellingi* × *ferrea* and *Regina*.—Plant robust; habit sub-erect; leaves large; colour bronze and rose, but not yet fixed. A very effective and promising variety.

*Barroni* × *terminalis* and *Regina*.—Plant of robust dwarf habit; colour bronze, heavily marked with pink and cream. Very fine and effective.

*Leucocilia* × *Cooperi* and *Regina*.—Plant tall and free; colour green and clear white. Distinct and effective.

*Picturata* × *nigrescens* and *Regina*.—Plant very massive; leaves broad and fine; colour deep olive-green, with a margin of mottled pink and red, promising to be constant. Very fine.

*Salmonia* × *concinnum* and *Regina*.—Plant of free upright growth; leaves long and tapering; colour green suffused with salmon, which may possibly deepen and lead to a new colour. Interesting.

*Triumphans*.—Plant of the same parentage and character as *Picturata*, but not mottled, and colours lighter and brighter. Good.

*Renardii* × *Cooperi* and *Regina*.—Plant moderately robust and of excellent habit; colour green, the new leaves creamy suffused with rose. Very attractive.

*Scottii* × *concinnum* and *Regina*.—Plant vigorous and dwarf; habit good; leaves broad and drooping; colour rich bronze; the upper leaves creamy suffused with pink. A handsome and promising variety.

*Pendens* × *Cooperi* and *Regina*.—Plant vigorous; leaves broad and elegantly arched; colour deep green, edged with rose and cream. Very attractive and fine.

*Stricta alba*.—Parentage doubtful, possibly × *nigrescens* and *Regina*. Plant free, erect; colour green marked with clear white. Distinct and fine.

*Garolette* (Mrs. Wills) × *concinnum* and *Regina*.—Plant medium, dwarf; leaves narrow, 1½ inch broad; colour bronze and magenta. A brilliant and striking variety.

*Voluta* × *Cooperi* and *Regina*.—Plant robust and forming a perfect massive pyramid of arched foliage; colour dark, the upper leaves edged with cream and suffused with rose. Very distinct and promising.

*Venusta* × *concinnum* and *Regina*.—A rich-coloured drooping variety. Very promising.

*Elisabetha* × *Cooperi* and *Regina*.—Plant massive and of fine habit; colour bronze and red. A fine and promising variety.

*Terminalis alba* × *terminalis* and *Regina*.—Plant tall,

erect; leaves narrow and pointed; colour green, freely marked with ivory white. Very effective, and a fine decorative variety.

*Rebecca* × *Cooperi* and *Begonia*.—Plant vigorous; leaves broad and wavy; colour magenta, pink, and green. Very bright and effective.

*Mabilis*.—Plant of medium growth; colour very brilliant pink. A glowing decorative variety.

*Eximia* × *excoelsa* and *terminalis*.—Plant robust and of fine habit, with noble arched leaves; colour dark bronze with a distinct red margin. A fine variety.

*Cantrellii* × *ferrea* and *excoelsa*.—In the way of, yet distinct from the preceding, and also a fine variety.

*Thoma* × *terminalis* and *concinnum*.—Plant medium; leaves narrow; colour bronze and pink.

The following are narrow-leaved varieties, and will be unsurpassed for dinner-table decoration. We have seen them under artificial light, and can testify to their elegance of form and richness of colour:—

*Frederici* × *congesta* and *Chelsoni*.—Plant medium; leaves narrow, graceful, and nicely arched; colours bronze and red, suffused with a tint of orange. A bright and glowing variety.

*Amalie* (Mrs. Bause) × *congesta* and pollen of *Begonia* and *terminalis* mixed.—Plant medium dwarf; leaves narrow and graceful; colours bronze, red, and pink. Excellent.

*Bella* × *excoelsa* and *terminalis*.—Plant similar in habit to the preceding; colour bronze, distinctly edged with red. A chaste and effective variety.

*Violacea* × *congesta* and *nigricans*.—Habit same as preceding; colour purple bronze. Distinct and effective.

*Earnesti* × *congesta* and *terminalis*.—Habit similar to *Bella*; colours bronze and bright red. A distinct and fine variety.

*Sydneji* × *concinnum* and *Begonia*.—Plant tall, leaves narrow and sub-erect; colour purple bronze. Distinct and effective.

*Renardii* × *congesta* and *Begonia* and *terminalis*.—Plant compact, graceful; colours similar to *Amalie*. Very attractive.

*Jocunda* × *limbata* and *terminalis*.—Plant tall; leaves narrow and very dark. Distinct and good.

Such is a hasty description of these remarkable hybrids. The colours are given as affording a general idea of the plants, which are, however, changing every day and unfolding fresh tints. Their colours, in fact, are not yet fixed, and can hardly be finally determined until the plants are grown from cuttings. Two or three tops which have been taken off and struck have become richer in colour than on the seedling plants; and it is highly probable that others will follow the same rule.

It is remarkable that plants of the same parentage are widely different in habit and colours. It is also noticeable that in no instance has *Begonia* been a seed-bearing parent, but has been freely used as a pollen plant, and with decided effect.

A gentleman when inspecting the plants—himself one of the first of British horticulturists and a collector of plants—pertinently observed that "It is now hardly necessary to imperil the lives of collectors in hunting-out new *Dracenas* from the dangerous wilds of the tropics, when they can be created in such diversified beauty at home, for nothing as yet received from abroad can equal these grand English hybrids."

We congratulate Mr. Wills on his good fortune, and Mr. Bause on this splendid evidence of skill in hybridisation. He has now revolutionised two genera of plants, and merits substantial honour and reward. We do not hesitate to say that there is not to be found in the whole civilised and uncivilised world such a valuable collection of *Dracenas* in the same area of space as can be now seen in the little span-roofed house at Anerley.

## THE PLAGUE OF ANTS IN SOUTH KENSINGTON.

THE wail of distress from that ant-infested district increases rather than diminishes. The lady writes to say that she has tried to extract from the *Journal of Horticulture* some crumbs of comfort in her sufferings from the plague of obnoxious creeping things in her house, which have taken the place of wasps and gnats—those well-known enemies of her youth. "I have had," she says, "the offices well painted, and every hole filled with putty, but still the horrible ants swarm. I believe they breed in the walls in consequence of the bad materials employed in building; but from whence they contrive to emerge puzzles us all. Now we are trying the plan suggested by the *Journal of Horticulture*, and we are laying traps for

them—scraps of meat or bacon, which, my servants assure me, attract thousands, and they have the most lively satisfaction in boiling them. Still there seems to be no diminution. They almost realise the old saying, 'Kill one, and ten come to the funeral.' We have endless companions in misfortune.

"I think South Kensington is particularly infested with them. Lord —'s house, next door, is so possessed by them that the servants have the greatest difficulty in keeping their provisions from these vermin, which seems to be still more numerous than with me. Do think of my ants, if you know of any one learned in such plagues. We have found out that the little wretches bite. Can any of your correspondents suggest other remedies? How would it answer to sprinkle Calvert's carbolic powder on the ants and on their runs? Would the smell be injurious to the inhabitants? I suspect these pests breed in the summer in the Horticultural Gardens, and then migrate into the houses around during the winter, to the great annoyance of the inhabitants."—O. M.

## OSMASTON MANOR,

THE SEAT OF J. WRIGHT, ESQ.—No. 2.

I CONCLUDED my notes last week by noticing the Vines, and will now pass on to the other houses devoted to the cultivation of fruit.

Peaches are grown at Osmaston on an extensive scale. They have a period of use of six months, commencing in April and continuing until the middle of October. The houses in which the trees are grown are light, lengthy, and lofty. In some of them the trees are trained up the back wall, the front of the houses being occupied by trees in pots plunged in the border. These comprise Plums and Cherries as well as Peaches and Nectarines. In other houses the trees are trained on a low semicircular trellis as well as on the back walls. The pot trees are extremely well grown; they are heavily cropped and richly fed, it not being unusual to ripen from four to six dozen Peaches on a pot tree. The trained trees are also in excellent order. Some of them are large, and bear from three hundred to five hundred fruit on each tree annually. I have never seen trees in better bearing condition than are these. The wood is not strong, but the foliage possesses that rich Portugal-Laurel green hue indicative of sound health.

Mr. Booth's principal stimulant is cow dung. The pot trees are heavily dressed with it, and the borders have a thick covering of it annually lightly surfaced with soil. As soon as a tree shows signs of exuberant growth it is carefully lifted and root-pruned, and the roots are kept near the surface. The ground is, in fact, completely netted with them, and the wood by this system of culture is of medium strength, short-jointed, and fruitful. An unlimited supply of water is laid on, and is used freely, the trees being regularly drenched in the growing season; and in the resting period the borders are not suffered to become in any degree dry. By these continued washings and rich surface-dressings red spider is never seen in these houses. The Peaches most esteemed are *Grosse Mignonne*, *Belle Bause*, *Royal George*, *Diamond*, *Noblesse*, and, as the best late sort, *Barrington*; the Nectarines which are mainly relied on being *Pitmaston Orange*, *Pine Apple*, *Violette Hâtive*, and *Victoria*.

Besides the vineries and Peach houses there are three ranges of span-roofed forcing pits devoted mainly to the cultivation of Pines, Melons, and Cucumbers. Pines are not extensively but well grown, the plants being in excellent order. Melons have during the past season been both numerous and fine, 180 excellent fruits having been cut from the house 20 feet by 12; the sort principally relied on being a splendid variety raised at Osmaston, and which is to be distributed during the ensuing season. The crop of Cucumbers has also been extraordinarily prolific, and beyond all doubt Mr. Booth has raised a variety of great merit. From a house of the dimensions given above 1864 Cucumbers have been cut varying from 24 to 32 inches. These fruits have been sufficient to supply a house of thirty-five persons besides what have been given away, and over and above these the surplus has realised by sale £20. The variety is as fruitful as *Telegraph*, one of its parents, and is much longer; but its chief merit consists in its keeping properties. Fruits were hanging in October on plants which had lost their foliage by old age, and these fruits were as green as ever: they appear, indeed, to refuse to turn yellow. The flesh was quite firm, although they had been hanging for months. It is clearly a variety of great value, but scarcely any seed can be had from it, and it is perpetuated by

cuttings; yet Mr. Booth has succeeded in saving a few hundreds of seeds which are to be distributed in the spring.

In addition to the structures devoted to fruit culture are also some spacious plant houses. Two of these are 50 feet square with unusually flat ridge-and-furrow roofs, one of them being glazed with rough glass. These houses are admirably adapted for growing huge specimens, and it was in them that Mr. Harrison perfected the Orchids, Ferns, &c., for which Osmaston was once famed. In the houses are healthy and valuable, if comparatively small, plants, which are principally grown for decorative purposes, as the furnishing of rooms, &c. They comprise *Dracenas*, *Palms*, *Pandanuses*, *Ferns*, and other ornamental plants. Amongst the latter some plants of *Todea superba* are in splendid order, and *Dichotoma japonica variegata* is in a flourishing state. Another of Mr. B. S. Williams's new plants, *Anthurium variegatum*, is greatly valued as a table plant, being distinct, elegant, and of easy culture. *Calanthes* are well grown, and *Urocolina pendula* is extensively cultivated as a bright-coloured autumn-flowering plant which has been recently noticed by Mr. Abbey. Another house contains *Asaleas*, of which there is a large collection, with hundreds of *Primulas*, *Cinerarias*, *Solanums*, &c., for the conservatory. These are also useful ranges of brick pits, which with their contents I cannot here detail.

The walls of the garden are well covered with fruit trees, especially Pears, and the crop is exceedingly fine. There were probably many sacks of *Marie Louise* alone, and other standard sorts are grown on an extensive scale. A wire trellis on the French system, about 100 yards in length and 15 feet in height, is also covered with Apples and Pears, and the crop is very large. Sixty sorts of Apples are grown; one named *Spencer's Seedling* being remarkably handsome, prolific, and esteemed as a valuable kind. Fruits are grown also on bushes, which were laden with produce; and the excellent and complete fruit room was at the time of my visit being filled to repletion.

Strawberries are admirably grown at Osmaston, and I have never seen such fine fruit as has been produced at this place, especially of *President* and *Oscar*. *Grove End Scarlet* is grown for preserving, and for this purpose the old sort has still no equal. The plants are planted early in soil trenched 8 feet deep, and enriched with manure and bones. They produce fine crops of very large fruit the first year, and prodigious crops of smaller fruit the second season, and are then destroyed. The plants would continue to bear longer and bear well, but by no other mode can Mr. Booth obtain such a full return of fine fruit as on the two-years system. He therefore clears and plants a given space of ground every year, as being the most profitable practice in Strawberry culture.

Vegetable culture is also conducted with the same care as fruit and plants, and as an instance of attention in this department Mr. Booth saves his own seed of a few standard sorts of Peas, selecting only the finest pods, and he finds the very best results follow this mode of selection. He finds *William I.* the best of all early Peas, and *Hair's Dwarf Mammoth* the most valuable of all late kinds. Of Celery, which is largely grown, the most approved sort is *Leicester Red*. The arrangements and appointments of this garden are very complete, and the management is as good as the means.

I now in conclusion, and as briefly as possible, revert to the ornamental features of Osmaston. The lawns and pleasure grounds are about 50 acres in extent, and are rich in trees, shrubs, and Conifers. The terraces are extensive, the fountains attractive, and the surrounding scenery—the heavily-wooded hills and valleys of verdure, with a glimpse of water through every vista—imposing. But I will first proceed to the

ROCKERY.—Our route is by a fine Yew hedge, and we pass golden piles of Hollies and many a valuable Conifer. Eventually we see a solitary rock, as if bursting its prison house the earth, then another and another. Following their track amongst the shrubs we come to a cavernous entrance. We stoop instinctively, but there is no occasion for stooping, for the entrance is ample. On either side the stony passage are fissures—yawning rifts, as if torn asunder by some superhuman power; passing these we enter the rock-bound dell. The rockery at Osmaston is not a huge pyramid of stones which we walk round to admire, or wonder why they were so placed. It is an amphitheatre, and we stand still and wonder that it is really a work of art. In the centre of the enclosure is an irregular stream of water; at its edge are Sedges and water plants, massive boulders protrude through its sides covered with Lichens and half hidden by Ferns. On drier knolls are

*Pampas Grass*, and scattered about in apparent abandonment are mammoth stones, Heaths, Ferns, *Asaleas*, and Conifers.

The sides of the amphitheatre are rugged rocks, clothed with foliage and draped with Alpine plants in great variety. In one corner *Aralia Sieboldi* luxuriates, in another *Yuccas* protrude from the fissures. On a knoll is *Sciadopitys verticillata* in excellent health, and the distinct *Cephalotaxas* in variety partially hide with their rich foliage the ponderous walls of rocks. A variegated Maple is dotted in here and there to give light to a somewhat sombre scene, and warmth of colouring is imparted by the glowing crimson of *Ampelopsis Veitchii*. What a fiery plant is this when in its last autumn garb! As a trailing, climbing, pendant plant for rocks, roots, walls, or trees it has no equal as a summer covering plant, green in spring, and of glowing richness in autumn. On the rocks at Osmaston it was precisely at home. We ascended from the dell by rough stone steps, and to look down on the scene below—the cascades, rocks, and foliage chaotically intermingled, one is not surprised that Mr. Parham considers the work as one of his greatest triumphs, for this natural-looking and wild picture is entirely artificial. The rocks were moulded by Mr. Parham, and the plants planted and tended by Mr. Wright and his gardeners Mr. Harrison and Mr. Booth, and the work does credit to them all. The whole work is complete; it was projected and carried out skilfully, and is kept and tended tastefully.

From the rockery we pass to the terraces. There are three tiers of these, each extending about 100 yards. On the lawn portion of them are planted standard *Rhododendrons*, standard *Portugal Laurels*, very fine; also American and other ornamental plants. They are further graced with fountains, and here and there a few beds of flowers; but flowers are sparingly used, and wisely so, on this dignified frontage, with the bold nature of the adjacent scenery. The terrace wall is covered with climbing plants, and on the walls of the mansion are *Magnolias*, a yellow *Banksian Rose*, 30 feet high, which flowers freely, and an equally fine plant of *Maréchal Niel*.

Conifers at Osmaston are extensively planted, and many fine specimens are to be seen. Not only the lawn and pleasure grounds contiguous to the mansion, but even the more distant woods are rich in many valuable plants of this nature. Mr. Wright is a great patron of ornamental trees, and with a considerable knowledge of them, combined with sound taste, he is constantly adding to the ornamentation of his estate. *Wellingtonias* may be seen by hundreds, one specimen which I noticed being about 36 feet in height, and is 5 feet round the stem at 2 feet from the ground. It is perfectly furnished, and in robust health. That is only an example of many others. *Cryptomeria japonica* is of the same height, and exceedingly dense. It is a wonderfully fine specimen of this fine Conifer. *Pinus Morinda* is in grand condition and similarly fine. There are also fine examples of *P. Nordmanniana* and *Piceas nobilis*, *amabilis*, *pinsapo*, and others. *Thuopsis dolabrata variegata* is freely planted, and the well-furnished specimens 8 feet in height are very attractive. All the new and choice *Retinosporas* are included, and are growing freely, and there are perfect cones of *Irish Yews*. *Deodars* and *Cedars of Lebanon* are numerous and fine, many of these having been successfully removed by Mr. Booth when 20 to 30 feet high. Time, care, and fresh soil are insisted on, and no hurrying or rough handling of the trees and roots is permitted in the removal of large trees, and it is rare indeed that a specimen has failed to grow.

This is but a cursory glance at the ornamental grounds of Osmaston, which are full of fine views and features which space does not permit me to detail.

The exit from the grounds is through an avenue of *Limes* and *Wellingtonias*, of which the terminal landmark is the village church. But this Lime avenue is not quite satisfactory, and affords an instance of the soundness of the remarks of Mr. Allis when he recently urged the importance of having all the trees of the same variety, and recommended as the best *Tilia rubra*. The trees are not all of the same variety, and they consequently vary in size and outline, but whenever we come to the kind recommended, the tree is not only much larger than others of the same age, but is more handsome in shape and outline. It is certainly a matter of great importance in avenue-planting to have all the trees of the same variety, as securing the uniformity of growth which is so essential.

There are many trees and Conifers which I have not noted, but there is one which I did not see in the grounds which is

worthy of a place there—*Cupressus Lawsoniana erecta viridis*, and which I beg leave to recommend as worthy Mr. Wright's notice.

I leave this fine place with the impression that in planting and management it bears the impress of skill and taste on the part of the late Mr. Wright and Mr. Harrison (now at Knowsley), and certainly not in a less degree does it that of the present owner and his industrious and able gardener Mr. Booth.—J. W.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

**THE GREENHOUSE.**—There are many things to attend to in this structure now that plants have been or ought to have been housed. In the first place, avoid overcrowding, and those plants that have been standing outdoors for a length of time must not be kept in a too dry atmosphere, neither must it be heated in mild weather. I allude to Camellias, Azaleas, Heaths, and Epacrises, as well as many other hardwooded plants which an amateur may feel inclined to grow. This too sudden change from an outdoor temperature often causes Camellia buds to drop off, and if in an unhealthy state some of their leaves also. Too much water and with bad drainage will induce the same thing. For the present, therefore, an occasional syringing the foliage of all these plants will do good. They must not have too much of that even; they ought to be allowed to become dry occasionally, or Heaths will be liable to mildew, and too frequent syringings will induce Camellias to flower too early, and those that lose their buds would be likely to start into growth, which would be at the wrong time of the year. Watering at the root is a different matter, for though Azaleas may not require so much water in winter as in summer, yet it is necessary that they should have sufficient, for their fine hair-like roots will not bear drought. But when a plant of this kind is watered give it sufficient to go through the ball of earth and then have done with it. On the other hand, such plants as Cactuses may be kept dry until the fleshy leaves begin to shrivel, then give water; but there are not many plants that will bear this. Achimenes and Gloxinias may be best preserved in the pots in which they grow for the present, and if they could stand on a damp bottom would receive moisture sufficient. The Gloxinia being more fleshy might bear it longer, but then it will not bear the cold so well as the Achimenes; therefore place these in the warmest part of the house.

Ventilation is another nice point to attend to. Just through this month, or even up to Christmas, there is frequently a stagnant outdoor atmosphere for days together; then it is necessary that a little fire heat should be given, and the bottom as well as top ventilators opened, so as to promote a circulation, or mildew makes its appearance.

Lachenalias are easily-grown bulbs, and should be encouraged in the cold frames at present. Primulas and Cinerarias, too, must be encouraged in every possible way, for now is their best time, and a check would be injurious to them.

Look sharp after green fly, which soon makes its appearance upon plants in a genial atmosphere. Most people make it a rule to fumigate their plants several times after they are housed, because those parent aphides that are brought in with the plants if not killed would soon increase, and cause much trouble to eradicate.

Forward with all dispatch the growth of Calceolarias in pots. All successions of them should be shifted on. They, too, will do in cool frames for the present, but must have plenty of air while the weather will allow it. Lilliums, some of the most beautiful plants grown, should now be potted, putting three or four bulbs into a pot, and let the bulbs be covered with about 4 inches of soil. We used to do them this way. Use good-sized pots, drain them well, half-fill the pot moderately firm with soil, place the bulbs on it, and cover them over with 4 inches of soil; place them either in a cold frame or in one corner of the garden under a wall, cover them with litter so that no frost can reach them; examine them after being potted a considerable time, and remove them from this only when the shoots are pushing through the soil; then place them in a cool frame, and for a few days protect them from much light until they show signs of becoming green, when they may have more of it; then clear the top soil off and add a little fresh, and as they grow add more. When the weather gets warm enough for other plants to stand outdoors let them do the same, and there they may remain till they flower. They like plenty of water, and as they approach flowering weak guano water may be given twice or thrice a-week, and they will bloom admirably about August.—THOMAS RECORD.

#### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

##### HARDY FRUIT GARDEN.

VERY little can be done in this department now that all the fruit has been gathered and the trees are rapidly shedding their leaves. We are preparing a border to plant out a few Apple

trees, and it is on ground where some old Bullace trees have been grubbed out. It would be foolish to plant any other trees on this ground without trenching it well up. The way this is done is to take out an opening at one end of the border 2 or even 3 feet deep, according to the depth of the soil. In our case we cannot go more than 2 feet, as the soil is not deep enough. The ground is full of old roots, which are carefully picked out, and as the soil is poor some rotted manure is worked in, and two barrowloads of good rich loam to every three square yards. The loam we consider of more importance than the manure. We would rather have trenched the ground six weeks ago, but the crop has just been cleared from the trees. At planting some fresh loam will be placed under and over the roots, and in this way the trees will get a good start. Probably next autumn the trees will be lifted, and the ground trenched over again, and the trees be replanted in fresh loam. In ground such as ours, where there is much tendency to canker, this lifting and replanting keeps the roots near the surface, and they are further induced to work upwards by the trees being mulched over the roots in winter, the mulching not to be removed, but left on to be washed in by the rains and bleached by the summer's sun. The borders are so full of roots that it is not possible to fork the ground over without injuring them, but in light soils digging fruit borders is very questionable practice. Two varieties of Apples not so well known as they ought to be have been added to our collection this year; they are grown to great perfection in Mr. Thompson's orchard at Ilford. The first is known as Brownlee's Russet, this is grown in quantity, and is very highly esteemed; the other is The Mother, an introduction from America. It was growing on an espalier, and the tree was loaded with large, handsome, highly-coloured fruit; its appearance is all in its favour as a market variety, but it is also of very good flavour; the fruit is in use in October.

We have cut away the old spent Raspberry canes, pruned and tied the young canes of this year into their places. Owing to so much wet the Strawberry quarters are very full of weeds, mostly grass, and this has been introduced with the loam used in putting out the young plants. It will not be possible to subdue them by hoeing, and at the first opportunity they must be removed by hand. Strawberries in pots have not yet been removed to the orchard house where they are wintered.

The Chrysanthemums are in full flower, and if it was necessary to water other plants on the shelves the damp arising therefrom would do much injury to the large flowers by causing the petals to become mouldy.

We would just allude to the fruit room. It is necessary to look over all the fruit at least twice a-week, and to remove such as have decayed or any that show symptoms of decay. There is now an over-abundance of fine Pears. The best that we have in use at present are Marie Louise, Doyenné du Comice, and Maréchal de Cour; these three are very distinct both in appearance and flavour. There are many others in use, of which the best are Beurré Superfin, Zéphirin Gregoire, Triomphe de Jodoigne, and Van Mons Léon Leclerc. Thompson's is a very fine October Pear, but it is now over.

##### FRUIT AND FORCING HOUSES.

**Vineries.**—We have not yet started the early houses, and we have given full instructions as to previous preparation of borders, washing and painting Vines, and limewashing walls. It would be well if the woodwork could be painted about once in two years. The hot-water pipes may be painted every year with lampblack and linseed oil. We have discontinued making up a bed of fermenting material in the house for the last three years, but the Vines certainly start more strongly when the heat from the pipes is supplemented by the genial steam from a bed of manure or leaves, or a mixture of equal proportions of both. It is necessary to turn over the bed occasionally, at the same time adding fresh material to keep up the heat. In our case it is necessary to use stable manure as leaves cannot be obtained, but if fresh Oak leaves could be obtained they would be used in preference. When a good bed of fermenting material was made up in the house even at midwinter, it was not necessary to use any other heat until the buds were well advanced, which saved fuel, as the fires were not required for three weeks or a month later than usual. The work in the late houses, and other instructions, is the same as that given on page 387.

##### GREENHOUSE AND CONSERVATORY.

Chrysanthemums make a very beautiful display now where the cultivation of them has been attended to, as it ought to have been. At Loxford the large orchard house is quite filled with plants, a very large proportion being grown to produce large blooms for exhibition. These plants are arranged closely together, the tallest plants at the back, and those that have been trained for other purposes and Pompons about a foot or 18 inches high near the front, so that the eye catches the whole mass of flowers in a gradual incline from back to front. The earliest-set buds always produce the largest flowers. Empress, of India, Prince Alfred, Prince of Wales, Princess of Wales Beethoven, and a few others are unusually large this year. It is necessary to look over the flowers very frequently, and remove

any decaying petals. Those who intend to exhibit will be careful to see that their best flowers are not injured by inattention to this, as one decaying petal will do very much mischief in a few days if it is unobserved. Mildew is also very troublesome. The plants are most persistently attacked by this parasite towards the end of September, and the only way to keep it in check is to dust the plants with flowers of sulphur as soon as it is perceived; but as mildew always does attack them, it is best to use sulphur as a preventive. Just before the buds are formed, or, indeed, all through the growing period, the plants are also attacked by aphids, which cluster in the centre of the young growths, and would quite spoil the bloom if they were not destroyed. Dipping the shoots in soapy water wherein some tobacco liquor has been mixed, or dusting with Scotch snuff, will destroy them.

Specimen plants are being trained to neat sticks. It is not desirable to finish tying them until the buds are well expanded, as they increase in growth up to the time the buds are about fully opened. The small Pomponne varieties require but few sticks. The growths are trained into the proper shape early in the season; the main stems are fastened at that time to supports to bring the plant into the required shape. Further training is unnecessary except to regulate any after-growths that may grow out of the required bounds. The plants require large supplies of water, but it must be applied to the plants carefully, and not be spilled about in the house. Moisture is very injurious to the flowers, and the largest and best blooms suffer first.

The Hyacinths and Tulips have just been potted. Many persons pot their bulbs as soon as they are received in September, and they ought to be potted early if they are intended for early forcing. The largest proportion of ours will flower late in the spring, and for this the last week in October or the first in November is the best time to pot. The soil used must be rich, but not too rich; an over-rich compost rots the roots, and the bells do not open well. We were recommended to pot our bulbs, by one who had ample means of knowing about the culture of Hyacinths, in well-rotted cow manure, the manure to be reduced to mould by laying for years exposed to the atmosphere. We tried two or three bulbs in this rich stuff, but not a root ran into it, and the plants came to nothing. Our compost for Hyacinths is about equal parts of cow manure, loam, leaf mould, and sand. For Tulips it is a mixture, except that stable manure is used instead of the other. After potting the pots are plunged in cocoanut fibre refuse out of doors. Leaf mould answers quite as well as the fibre refuse. Ashes have been recommended very frequently, but we have not found them to answer so well. The bulbs should be plunged out of doors, and not be protected from the weather in any way. The plunging material should be about 4 inches over the pots.

Now is a good time to destroy any insect pests should the slightest trace of them be seen. There are few houses quite free from either thrips or green fly, and by fumigating now at intervals of two days the insects may be quite destroyed. It may be done three times, and then at an interval of ten days smoke again.

#### FLOWER GARDEN.

The weather has been fine for the last week, which gave us an opportunity to get all the Gladioluses out of the ground. The best plan is to dig them up with a fork and cut the stem off close to the bulb. At the same time the bulbs are spread out in a dry place, or if there be only a few roots of a sort the roots are placed in flower pots and left there until they are quite dry. If it is desirable to increase the stock of any particular variety all the spawn that clusters round the base of the roots is saved and potted, the spawn is potted at once, and the pots are plunged in a cold frame, or anywhere if they can be sheltered from too much rain. The roots are very large, and with few exceptions are perfectly sound; we took the precaution of pulling out all plants that were unhealthy at the time of flowering.

Carnations and Picotees that were potted a few weeks ago have been looked over and all decaying leaves removed. The pots are now plunged to the rim in cocoanut fibre refuse, the plants being only a few inches from the glass. The Pinks were planted out near the end of October, and will require no attention, except to press the plants firmly into the ground after frosts. Those who grow Pinks and have not yet planted out should do so at once; spring planting produces imperfectly-laced flowers. All the bedding-out plants have been removed and the ground made neat for the winter. These beds that are planted with spring-flowering plants are now being filled.—J. DOUGLAS.

**CHRYSANTHEMUMS.**—I was very much pleased with a collection I saw on the 2nd grown by Mr. Goff, an amateur, on the premises of the Waterworks, opposite St. George's Church, Campden Hill, Kensington, the whole of which are in pots. A few which I thought especially worthy of notice are Alfred Salter, light pink; Aurea Multiflora, yellow; Jardin des Plantes, bronze and yellow; Empress of India, white; Globe, white;

Helaine, large, white, very fine; Lady Margaret, white; George Sands, red with gold centre; Prince of Anemones, large lilac.—WILLIAM GARDINER.

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LOUGHBOROUGH.—November 15th and 16th. Mr. W. Pallett, 55, Baxtersgate, Sec.

NORTHAMPTON (Chrysanthemums).—November 16th and 17th. Mr. N. Gutteridge, 51, Denmark Road Sec.

#### TRADE CATALOGUES RECEIVED.

Thomas Bunyard & Sons, Ashford and Maidstone.—*Catalogue of Roses.*

Maurice Young, Milford Nurseries, Godalming, Surrey.—*Catalogue of Conifera, Rhododendrons, Forest Trees, Roses, &c.*

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

**NAMING PLANTS AND FRUITS.**—Some of our readers are aggrieved because the names are sometimes not promptly announced, but the delay is often unavoidable. It is no easy effort of memory to identify a specimen belonging to kinds having hundreds of kindred.

**BOOKS (E. S. T.).**—Our "Orchid Manual" and "Fern Manual" would suit you.

**GRAPES AT THE EDINBURGH SHOW.**—We are officially informed that Mr. Thomson of the Tweed Vineyard undertook to reply on the whole question for the Royal Caledonian Horticultural Society, both as one of the Managing Committee, and as a Judge at the late International Show. We have received several letters on the subject, half of them asserting and half denying that the prize was awarded to a double bunch. We cannot publish more on the subject.

**ROSES (E. S.).**—Why do you trouble yourself about standards? Unless on thoroughly good Rose soils they are generally troublesome and dwarf. On either the seedling Briar or Manetti Roses would be much more satisfactory. You procured the Briars lately, but October is much too early to dig them up, and although they may survive, which is very doubtful, if they fall you must not attribute their failure to being cut, but to their being taken up while the sap was still flowing. As to the sorts named, Capitaine Christy, Baron Bonstetten, Eugénie Verdier, Marie Comet, Mons. Noman, Etienne Levet, and Prince de Portia are good Roses, and good growers when grown on suitable stocks, Mdlle. Eugénie Verdier perhaps the most delicate of the lot.

**CROP OF GRAPES (R. Jordan).**—The crop of Black Hamburgs at the Rev Mr. Hayworth's was good, but there being nothing in the culture special there would be no instructive information if we published your letter.

**KITCHEN GARDEN WALKS (A. Dumbell).**—Gravel would do for facing instead of granite chippings.

**SUTTON'S IMPROVED READING ONION (Inquiring Tyro).**—We cannot inform you of the particulars you need. Write to Messrs. Sutton and ask them.

**THE BANKMAN MEDAL (Subscriber).**—The Royal Horticultural Society's medal was so named in honour and commemoration of Sir Joseph Banks.

**FRUITS FOR NORTH CAROLINA (H. H. F.).**—We cannot recommend tradesmen. Go to any nurseryman near you, and inform him what you need. Any of the Rhubarbs and Raspberries would succeed.

**EDWARDSIA MICROPHYLLA CULTURE (Amateur in Trouble).**—The spray sent is of the plant above named. It is an evergreen shrub with yellow flowers, which are produced in early summer outdoors against a south wall, and in April or May when grown in a cool greenhouse. It is a native of New Zealand. To flourish well in the open air it requires to be planted in front of a south wall, and its shoots trained thereto, planting in a compost of fibrous sandy peat and turfy loam in equal proportions, and after removing the soil from a semicircle drawn with a radius of 8 feet from where the shrub is to be planted 2 feet deep, place some rough material at the bottom, as charcoal or broken stones 6 inches deep, fill in with the compost above named, and introduce the shrub, planting it on a raised but flattened cone about 6 inches above the surrounding ground level, and give moderate watering. This we should advise to be done now, lifting carefully, securing the shoots to the wall. Water copiously during dry weather in summer, and syringe overhead in dry hot weather, but after the middle of September keep dry both overhead and at the roots. The shoots should be trained rather thinly, but so as to cover the wall.

**PEARS AND PLUMS FOR NORTH WALL (S. W.).**—The following Pears are likely to succeed:—Jargonelle, Williams's Bon Chrétien, Beurré de Capiaumont, Achan, Beurré Bachelier, and Knight's Monarch. Plums: Angelina Burdett, Aunt Ann (Guthrie's), Oullin's Golden Gage, Prince Englebert, Winesour, and Victoria. For the south wall of the dairy Marie Louise Pear will be suitable.

**OCTOBER-GROWING (Ipewich).**—In our "Kitchen Gardening," which you can have free by post if you enclose five postage stamps with your address, you will find full directions. Our "Orchid Manual" you can have in the same way if you enclose thirty-two postage stamps.

**PRELARGIUM LOSING COLOUR (G. B.).**—It is due to want of light, and want of heat and moisture, so as to secure free growth. The plant will not recover its high leaf-colouring until spring, when with fresh growth the colours will be good. Keep rather dry during the winter, and repot in spring.

**ILLUSTRATIONS OF PLUMIERIA ALBA AND BICOLOR (Idem).**—*P. bicolor* is a synonyme of *P. alba*, which is figured in Jacquin's "*Stirpium Americanum*." *Plumieria tricolor* in the "*Botanical Register*," pl. 510. The specimens had no number.

**RANUNCULUS AND ANEMONES PLANTING (F. H.).**—The Turbans should be planted between now and January, and the Persian varieties of *Ranunculus* from January, and *Anemones* from now to February, just as you wish for an early or late bloom. With fine named varieties the latter-mentioned date is preferable.

**HEATING WITH PEAT (W. W.).**—We have no experience of heating with ordinary peat turf, but the compressed peat answers well for stove-hot-water boilers with hot-water pipes for diffusing the heat, and in all probability ordinary peat turf would answer. A small stove boiler with a flow and return 2-inch hot-water pipe would, along the sides of the house all around, probably meet your requirements, but we do not know of any stove or furnace specially constructed for consuming peat. Perhaps some of our readers may have experience on the matter.

**CATCHING RABBITS (W. W.).**—We know of no trap but the box one with the table in the centre letting loose the spring doors, and these placed at the mouth of their burrows may take some; but a far better plan is to turn a muskrat ferret into the burrows, with a rabbit net over each of the bolt holes as well as the entrance.

**BLIGHT ON FRUIT TREES (J. P. of York).**—We presume green and black aphids is meant by green and black blight, either of which may be destroyed by syringing with tobacco juice diluted with six times its volume of water, holding in solution 2 ozs. of soft soap per gallon. The trees being young, and we presume weak, would be improved by giving a liberal dressing of manure, which we would give now, and potting-in with a fork, but not disturbing the roots, treading firm afterwards if a light roll, and mulching for at least a yard from the trees all around, with short rather littersy manure 2 or 3 inches thick.

**FORCING AZALEA ARGENT, LILY OF THE VALLEY, SPIRÆA, AND DEUTZIA (A Subscriber).**—You may place them all in heat now; the *Azalea* and *Lily of the Valley* especially, giving the latter the benefit of a mild bottom heat if you have it, and the *Azalea* a temperature of 55° from fire heat, and 10° higher by day, which will suit *Lily of the Valley*, placing it near the light. *Spiræa japonica* and *Deutzia gracilis* ought not to be started until the middle of December, and they are better if not placed in heat until the early part of January. They require to be brought on gradually.

**WINTER TEMPERATURE FOR VARIOUS PLANTS (Idem).**—*Euphorbia splendens*, *Gloxinias*, *Gesnerias*, *Coleus*, *Begonia*, *Poinsettias*, *Stephanotis*, &c., require a temperature of 55°—50° night, 65°—60° day, the lower temperature being in severe weather, and with sun and air 70° to 75° by day. The plants should only have water to maintain them fresh. If you wish them to grow the temperature should be 5° higher upon all the temperatures named, but the cooler and drier they are kept with safety to the plants the better they will do when subjected to heat and moisture.

**BUNCHES OF GRAPES FROM ONE EYE (Hortus).**—We do not consider the terms "joint" and "eye" are synonymous. Two eyes or more, as in the shoot sent to us, may proceed from one joint, and the bunches of Grapes on the shoot were twins, each from a separate eye united at their bases. We cannot insert more.

**CLIMBERS FOR NORTH WALL (M. M. T.).**—Evergreens are Ivy and *Cotoneaster microphylla*. Deciduous are *Ampelopsis Veitchii* and *A. hederacea*.

**VIOLAS (A. B. C.).**—There is no necessity to replant them; they will bloom again next year, whether left where they are this year or removed.

**NAMES OF FRUITS.**—[We do not reply to communications through the post, and we cannot name more than six fruits at one time.]—(W. H. Bois).—Beauty of Kent. (*Vesta*).—1, Doyenné Bouschet; 2, Vicar of Winkfield; 3, Winter Nellis; 4, not known. (W. K.).—Belsette du Canada; 2, Lewis's Incomparable; 3, Dunselow's Seedling. (St. Vincent & Down).—1, Golden Belsette; 2, Five-crowned Pippin; 4, English Codlin; 5, Pearson's Plate; 6, Fearn's Pippin. Pear No. 2, Beurré Rance. (*Offton*).—Marie Louise.

**NAMES OF PLANTS (H. W.).**—*Coriaria nepalensis*. (W. G. Green).—*Bom viridiflora*. It was portrayed in this Journal some years since.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### HANLEY POULTRY SHOW.

THIS Exhibition was held on the 3rd and 4th inst. We were sorry to find so few entries, but the Show has never seemed well patronised, yet the Committee issue a schedule with plenty of classes and good prize money. The poultry Judges were Mr. John Martin and Mr. Hutton, and their awards seemed to give general satisfaction. The quality was certainly good throughout the Show, and though many of the classes were small winning was by no means easy.

**Dorkings** had two classes, and the Coloured were quite a nice collection. The pair which won the extra were really capital; the pullet a great beauty. In Whites we believe the second-prize bird was the cup Alexandra Palace cockerel. Somehow he is not quite our fancy, though a smart bird. A nice pen of Silver-Greys were first, and Whites again third. *Spanish* made a nice class, and the winners well selected, and looked well. *Cochins* were a good lot in quality. A very fine pen of Whites here won the extra. We believe it was the cup pen at Edinburgh; if so, the cock has improved. Buffs were a nice lot, but nothing equal to what there was at Oxford the week before. Partridge were very fine. A capital old cock won first with a neat hen; second also good, as too was Mr. Tudman's pen. In the Variety class a pretty pair of Blacks were first, Cuckoos

taking second, and third again going to a fair pair of Blacks. Altogether the *Cochins* were a great feature in the Show. *Brahmas* were beautiful, the Darks being wonderfully good, and Mr. Ansdell's birds well to the front. Mr. Percival sent a good pen, and so did Mr. Pritchard, but nothing could fight against the winning old cock. Lights were only three pens in number, but the quality was very fair indeed, the winners walking-in easily. *Polish* were only a small collection. Fine Silvers, really good in crests, won, we believe, the extra for this section; and Golds took second and third, there not being much between the quality of the two latter pens. *French* were two nice classes. Old birds came off best in Crêves, though Mr. Knight's chickens were well-grown birds. *Houdans* were very good, and the winners rightly placed. The Variety class was conspicuous for a capital pen of Malays and some very pretty Sultans. We are pleased to find this extremely ornamental variety so generally looking-up, and to see so many new fanciers for Miss Watta's old friends the Serai Taoooks. By-the-by, we believe this lady first introduced them, and then we believe they had five toes; we mention it, as there is at present a doubt as to the necessary number. *Game* were splendid classes. The Duke of Sutherland sent a fine team, as too he did in Hamburgs, and his birds were certainly shown in beautiful condition. A Black Red cock took the extra, and we think deservedly, though the winning Brown Red was a grand bird and in admirable feather. We again saw here one or two fine undubbed cockerels, and shall expect this class at the Palace to be a most interesting one. There was a nice pen of Piles shown, which took the China extra in Classes 18 and 19. Game hens were all good, and we much liked the first-prize Black Red hen. In Duckwings the quality was not over-good, the first-prize pen coming easily to the front, second and third being moderate. *Hamburgs* were very good; the competition was mostly between a few yards, and the prizes were for the most part fairly distributed. We believe the extra went to Golden-pencils, but are not certain; if so, we think they had it properly, as the pullet was certainly a gem. Blacks were good, and the winners all of good colour. The Silver-pencils were very even in quality, all the prize birds being of great merit. Silver-spangles were a capital lot, and the winners seemed well placed. The second-prize pen was, we hear, the same pen as won that honour at Oxford; if so, we think they looked better here even than there. *Bantams* were all good, but the classes were not large. Perhaps, as a class, the Variety class was the best, for the Laced and White-booted were very good. There was also a tidy pen of Pekins here. Blacks were good, and the winners well placed. We saw, too, a very stylish pen of Duckwings in the Variety Game class. Ducks were a fine lot, and Mr. Walker literally marched-in, and had a regularly good turn. His birds were all good and nicely shown. In Variety Ducks pretty Mandarins won first, and good Black East Indians the third place. *Geese* and *Turkeys* were good though not large classes. We furnish full awards below, though we are not certain as to the correctness of the awards in the extra prizes. The Local classes contained some good birds, as also the Selling classes.

*Pigeons* had 142 entries, and in some of the classes the quality was very good. The Carriers, in which Black and Dun won respectively, were a capital lot, as also the Pouters, which were first Black and second Blue, although the system of cock and hen in one pair showed less to advantage here than in any other. In Dragoons first were Blue and second Yellow. This was a fair class. Antwerps were well placed, the second, though once good, having seen their best days. English Owls were not a good class, and the winners rather plain, the first Blue and second Silver. Pen 53 (Thresh) we thought very good. Owls any other were mostly Whites, and well placed. Fantails a nice lot, as also the Nuns. Turbits we thought but moderate. Barbs were really grand, and Blacks won the prizes. In Tumblers the first were Almond and second Black Mottle, which we preferred; the former, though good in colour, were rather plain-headed. In the Variety class Grey Frillbacks were first and Blondinettes second. The Pigeons were very badly placed as to light, and it was surprising the awards were so well made under the circumstances.

*Cage Birds* were placed on the centre table of this room, and as in the case of Pigeons, the light was very bad. Plain Belgians were a very good class, the first a stylish good-positioned bird; the second a Buff, losing only in want of condition. Crested Belgian were not as good, being a little coarse. Yellow Norwich were all of the highly-fed variety, the three first-named standing quite out from the rest; only the winners in Buffs being of high merit. The Variegated were very good in colour, and the winners Yellows. Next to the Belgians Lizards stood well for quality, both classes producing birds of great merit, though the awards did not go in all cases to the most highly-peppered birds. Of Mules there were but four birds in the two classes, the first in both cases being even four-pointed birds. Goldfinches were a good lot in all respects, but the moulted Linnets did not show to advantage, not being as forward.

**Rabbits** had four classes, that of Lops being good, the first and extra for the best going to a Tortoiseshell buck, evidently young, but of grand style and carriage, 2½ by 4½; hard ran by a Black doe, 8½ by 4½. No. 19 (Schobold), Fawn-and-white, was 2½ by 4½, but in very bad order, many others measuring well up to these lengths. Himalayans were only moderate in quality. Angoras were very good; the first a grand Rabbit in both wool and size. In the Variety class the first was a pretty good Silver-Grey, and second a Blue Dutch. Several other Silver-Greys were nice and even in the colour, but some too dark on head.

**DORKINGS.**—Dark Coloured.—1, 2, and Extra, J. Walker. 3, J. White. 4, W. Badger. 5, H. King. 6, J. Scott. 7, and other variety.—1, J. Walker. 2, W. Badger. 3, T. Foster, jun.

**SPRINGERS.**—1 and Extra, T. Moore. 2, S. L. Edwards. 3, R. Jackson. 4, T. Powell.

**COCKS.**—Cinnamon and Buff.—1, W. H. Crabtree. 2, J. Walker. 3, T. Strick. 4, Brown or Partridge feathered.—1, A. Bamford. 2, W. H. Crabtree. 3, L. Aspin. 4, R. Taitman. 5, R. P. Farnival. 6, F. Bennett. 7, White.—1 and Extra, R. P. Farnival. 2, R. Baldon. 3, W. Whitworth, jun. 4, and other variety.—1, W. Badger. 2, L. Aspin. 3, G. Finty. 4, R. H. Wood. 5, R. Dagshaw.

**MAINE PHEASANT.**—Dark.—1, 2, and Extra, T. F. Asquith. 3, F. Holbrook. 4, Light.—1, R. F. Farnival.

Inspector. R. G. W. Southby.

land. 5, Duke of Sutherland.

**MAINE PHEASANT.**—Silver-splashed.—1 and 2, Duke of Sutherland. 3, H. Baldon. 4, H. M. King. 5, J. Scott. 6, J. Walker. 7, and other variety. 8, R. W. Brown.

**GAME BIRDS.**—Black-breasted Red.—1 and Extra, H. Baldon. 2, J. Smith. 3, A. Heath. 4, and other variety.—1, J. Smith. 2, J. Osoch. 3, P. Maitland. 4, H. Baldon.

**HANTAMS.**—Black or White, Clean-legged, not Game.—1, R. H. Ashman. 2, H. Baldon. 3, W. H. Ashman. 4, J. Clancy. 5, J. May. 6, and other variety. 7, Game.—1, 2, and Extra, M. Lane. 3, R. B. Smith. 4, R. A. Schuster. 5, F. Holbrook. 6, F. Hodge. 7, G. Holloway, jun. 8, J. W. Lloyd.

**DORKING.**—Brown.—1 and 2, J. Walker. 3, Duke of Sutherland. 4, P. Unsworth. 5, A. T. Miller. 6, R. Bell. 7, White. 8, J. Walker. 9, and 10, J. Walker. 11, and 12, J. Walker. 13, and 14, J. Walker. 15, and 16, J. Walker. 17, and 18, J. Walker. 19, and 20, J. Walker. 21, and 22, J. Walker. 23, and 24, J. Walker. 25, and 26, J. Walker. 27, and 28, J. Walker. 29, and 30, J. Walker. 31, and 32, J. Walker. 33, and 34, J. Walker. 35, and 36, J. Walker. 37, and 38, J. Walker. 39, and 40, J. Walker. 41, and 42, J. Walker. 43, and 44, J. Walker. 45, and 46, J. Walker. 47, and 48, J. Walker. 49, and 50, J. Walker. 51, and 52, J. Walker. 53, and 54, J. Walker. 55, and 56, J. Walker. 57, and 58, J. Walker. 59, and 60, J. Walker. 61, and 62, J. Walker. 63, and 64, J. Walker. 65, and 66, J. Walker. 67, and 68, J. Walker. 69, and 70, J. Walker. 71, and 72, J. Walker. 73, and 74, J. Walker. 75, and 76, J. Walker. 77, and 78, J. Walker. 79, and 80, J. Walker. 81, and 82, J. Walker. 83, and 84, J. Walker. 85, and 86, J. Walker. 87, and 88, J. Walker. 89, and 90, J. Walker. 91, and 92, J. Walker. 93, and 94, J. Walker. 95, and 96, J. Walker. 97, and 98, J. Walker. 99, and 100, J. Walker. 101, and 102, J. Walker. 103, and 104, J. Walker. 105, and 106, J. Walker. 107, and 108, J. Walker. 109, and 110, J. Walker. 111, and 112, J. Walker. 113, and 114, J. Walker. 115, and 116, J. Walker. 117, and 118, J. Walker. 119, and 120, J. Walker. 121, and 122, J. Walker. 123, and 124, J. Walker. 125, and 126, J. Walker. 127, and 128, J. Walker. 129, and 130, J. Walker. 131, and 132, J. Walker. 133, and 134, J. Walker. 135, and 136, J. Walker. 137, and 138, J. Walker. 139, and 140, J. Walker. 141, and 142, J. Walker. 143, and 144, J. Walker. 145, and 146, J. Walker. 147, and 148, J. Walker. 149, and 150, J. Walker. 151, and 152, J. Walker. 153, and 154, J. Walker. 155, and 156, J. Walker. 157, and 158, J. Walker. 159, and 160, J. Walker. 161, and 162, J. Walker. 163, and 164, J. Walker. 165, and 166, J. Walker. 167, and 168, J. Walker. 169, and 170, J. Walker. 171, and 172, J. Walker. 173, and 174, J. Walker. 175, and 176, J. Walker. 177, and 178, J. Walker. 179, and 180, J. Walker. 181, and 182, J. Walker. 183, and 184, J. Walker. 185, and 186, J. Walker. 187, and 188, J. Walker. 189, and 190, J. Walker. 191, and 192, J. Walker. 193, and 194, J. Walker. 195, and 196, J. Walker. 197, and 198, J. Walker. 199, and 200, J. Walker. 201, and 202, J. Walker. 203, and 204, J. Walker. 205, and 206, J. Walker. 207, and 208, J. Walker. 209, and 210, J. Walker. 211, and 212, J. Walker. 213, and 214, J. Walker. 215, and 216, J. Walker. 217, and 218, J. Walker. 219, and 220, J. Walker. 221, and 222, J. Walker. 223, and 224, J. Walker. 225, and 226, J. Walker. 227, and 228, J. Walker. 229, and 230, J. Walker. 231, and 232, J. Walker. 233, and 234, J. Walker. 235, and 236, J. Walker. 237, and 238, J. Walker. 239, and 240, J. Walker. 241, and 242, J. Walker. 243, and 244, J. Walker. 245, and 246, J. Walker. 247, and 248, J. Walker. 249, and 250, J. Walker. 251, and 252, J. Walker. 253, and 254, J. Walker. 255, and 256, J. Walker. 257, and 258, J. Walker. 259, and 260, J. Walker. 261, and 262, J. Walker. 263, and 264, J. Walker. 265, and 266, J. Walker. 267, and 268, J. Walker. 269, and 270, J. Walker. 271, and 272, J. Walker. 273, and 274, J. Walker. 275, and 276, J. Walker. 277, and 278, J. Walker. 279, and 280, J. Walker. 281, and 282, J. Walker. 283, and 284, J. Walker. 285, and 286, J. Walker. 287, and 288, J. Walker. 289, and 290, J. Walker. 291, and 292, J. Walker. 293, and 294, J. Walker. 295, and 296, J. Walker. 297, and 298, J. Walker. 299, and 300, J. Walker. 301, and 302, J. Walker. 303, and 304, J. Walker. 305, and 306, J. Walker. 307, and 308, J. Walker. 309, and 310, J. Walker. 311, and 312, J. Walker. 313, and 314, J. Walker. 315, and 316, J. Walker. 317, and 318, J. Walker. 319, and 320, J. Walker. 321, and 322, J. Walker. 323, and 324, J. Walker. 325, and 326, J. Walker. 327, and 328, J. Walker. 329, and 330, J. Walker. 331, and 332, J. Walker. 333, and 334, J. Walker. 335, and 336, J. Walker. 337, and 338, J. Walker. 339, and 340, J. Walker. 341, and 342, J. Walker. 343, and 344, J. Walker. 345, and 346, J. Walker. 347, and 348, J. Walker. 349, and 350, J. Walker. 351, and 352, J. Walker. 353, and 354, J. Walker. 355, and 356, J. Walker. 357, and 358, J. Walker. 359, and 360, J. Walker. 361, and 362, J. Walker. 363, and 364, J. Walker. 365, and 366, J. Walker. 367, and 368, J. Walker. 369, and 370, J. Walker. 371, and 372, J. Walker. 373, and 374, J. Walker. 375, and 376, J. Walker. 377, and 378, J. Walker. 379, and 380, J. Walker. 381, and 382, J. Walker. 383, and 384, J. Walker. 385, and 386, J. Walker. 387, and 388, J. Walker. 389, and 390, J. Walker. 391, and 392, J. Walker. 393, and 394, J. Walker. 395, and 396, J. Walker. 397, and 398, J. Walker. 399, and 400, J. Walker. 401, and 402, J. Walker. 403, and 404, J. Walker. 405, and 406, J. Walker. 407, and 408, J. Walker. 409, and 410, J. Walker. 411, and 412, J. Walker. 413, and 414, J. Walker. 415, and 416, J. Walker. 417, and 418, J. Walker. 419, and 420, J. Walker. 421, and 422, J. Walker. 423, and 424, J. Walker. 425, and 426, J. Walker. 427, and 428, J. Walker. 429, and 430, J. Walker. 431, and 432, J. Walker. 433, and 434, J. Walker. 435, and 436, J. Walker. 437, and 438, J. Walker. 439, and 440, J. Walker. 441, and 442, J. Walker. 443, and 444, J. Walker. 445, and 446, J. Walker. 447, and 448, J. Walker. 449, and 450, J. Walker. 451, and 452, J. Walker. 453, and 454, J. Walker. 455, and 456, J. Walker. 457, and 458, J. Walker. 459, and 460, J. Walker. 461, and 462, J. Walker. 463, and 464, J. Walker. 465, and 466, J. Walker. 467, and 468, J. Walker. 469, and 470, J. Walker. 471, and 472, J. Walker. 473, and 474, J. Walker. 475, and 476, J. Walker. 477, and 478, J. Walker. 1243, and 1244, J. Walker. 1245, and 1246, J. Walker. 1247, and 1248, J. Walker. 1249, and 1250, J. Walker. 1251, and 1252, J. Walker. 1253, and 1254, J. Walker. 1255, and 1256, J. Walker. 1257, and 1258, J. Walker. 1259, and 1260, J. Walker. 1261, and 1262, J. Walker. 1263, and 1264, J. Walker. 1265, and 1266, J. Walker. 1267, and 1268, J. Walker. 1269, and 1270, J. Walker. 1271, and 1272, J. Walker. 1273, and 1274, J. Walker. 1275, and 1276, J. Walker. 1277, and 1278, J. Walker. 1279, and 1280, J. Walker. 1281, and 1282, J. Walker. 1283, and 1284, J. Walker. 1285, and 1286, J. Walker. 1287, and 1288, J. Walker. 1289, and 1290, J. Walker. 1291, and 1292, J. Walker. 1293, and 1294, J. Walker. 1295, and 1296, J. Walker. 1297, and 1298, J. Walker. 1299, and 1300, J. Walker. 1301, and 1302, J. Walker. 1303, and 1304, J. Walker. 1305, and 1306, J. Walker. 1307, and 1308, J. Walker. 1309, and 1310, J. Walker. 1311, and 1312, J. Walker. 1313, and 1314, J. Walker. 1315, and 1316, J. Walker. 1317, and 1318, J. Walker. 1319, and 1320, J. Walker. 1321, and 1322, J. Walker. 1323, and 1324, J. Walker. 1325, and 1326, J. Walker. 1327, and 1328, J. Walker. 1329, and 1330, J. Walker. 1331, and 1332, J. Walker. 1333, and 1334, J. Walker. 1335, and 1336, J. Walker. 1337, and 1338, J. Walker. 1339, and 1340, J. Walker. 1341, and 1342, J. Walker. 1343, and 1344, J. Walker. 1345, and 1346, J. Walker. 1347, and 1348, J. Walker. 1349, and 1350, J. Walker. 1351, and 1352, J. Walker. 1353, and 1354, J. Walker. 1355, and 1356, J. Walker. 1357, and 1358, J. Walker. 1359, and 13

only of moderate quality. Jonque Cinnamons were well placed, but we should have reversed the first three awards in Jonque Cinnamons. In Mealy Goldfinch Mules the first was a nice bird, but much like a hen, eyes and wings evenly marked. In the open classes were some grand specimens of every variety, and as a rule the awards were well made. One exception, however, we could not understand—namely, the first in Evenly-marked or Variegated Norwich Jonque birds was really an unevenly-marked bird, while there were many good birds perfectly marked—a point we may be pardoned for looking upon as the summit of all breeding.

**COCHINS.**—1, A. H. Hunt, Rickmansworth. 2, Rev. R. Fielden, Macclesfield Rectory, Derby. 3, R. Russell, Derby. 4, W. G. Waters, F. Holbrook. 5, W. Harvey, R. P. Percival.  
**BRAMA POOTRAS.**—Dark.—1, F. Holbrook, Derby. 2, H. Chawner, jun. 3, E. Ryder, Hyde, Manchester. 4, H. Chawner, jun. 5, Dr. Holmes, C. Coppack, Dr. Holmes, W. Whitaker, M. Leno, F. Holbrook. Light.—1, R. P. Percival, Northenden, Manchester. 2, J. Widdowson, Derby. 3, D. Sealey, Redditch. 4, S. T. Vernon, T. Bold. 5, W. Thorn, H. Feast.  
**GAMES.**—Black Red.—1, F. Ward, Maidstone. 2, C. Spencer, Tulse, & F. Woods, Workshop. 3, F. Sale, Duke of Sutherland. 4, G. Barnesby, J. Filkin, J. Payne, Brown Red.—Medal, J. Richardson, Loughborough. 2, T. Dyson, Halifax. 3, H. E. Martin, Fakenham. 4, Duke of Sutherland, J. Cook. 5, T. Whittingham, J. Stoppard, F. Sale, F. Ward, J. Greenwood. Any other variety.—1, Duke of Sutherland, Stoke-on-Trent. 2, G. Barnesby, Derby. 3, F. Sale, Derby. 4, E. Bell, C. J. Moulds.  
**GAMES.**—Coke.—1, Duke of Sutherland. 2, H. E. Martin. 3, G. Lucas, Mansfield. 4, T. Spencer, W. Beresford, F. Sale. 5, W. T. Everard, F. Sale, E. Merrin.

**HAMBURGERS.**—Gold and Silver-pencilled.—Medal, Duke of Sutherland. 1, H. Pickles, C. W. Gibbs, Sutton Bridge. 2, H. Kidger, C. F. W. Meynell, W. Dixon, jun. 3, W. Ballam, Gold and Silver-spangled.—1, Duke of Sutherland. 2, T. E. Jones, Wolverhampton. 3, H. Pickles, Ebury, Leeds. 4, J. Overend, H. Blackley, R. E. Atkin, jun. 5, May, S. W. Hallam. 6, S. W. Hallam.

## YOUNG BIRDS.

**CARRIERS**.—1, W. Harvey. 2, E. Brown. vhc. J. Deakin. Ac. E. Brown, H. Brown, S. Hill, J. Deakin.  
**POUTERS**.—1 and vhc. W. Harvey. 2, H. Brown. Ac. and c, G. Crookes.  
**TUMBLERS**.—Short-faced.—1, 2, and he, A. Silvester. vhc. S. Hill. Other varieties.—1 and 2, A. Silvester. Ac. W. Harvey. c. S. Hill, J. Smith (2).  
**JACOBIANS**.—1 and c, W. Harvey. 2, J. Smith. vhc. S. Hill. Ac. J. Smith, E. Brown.  
**OWLS**.—English.—1, S. Hill. 2, W. Harvey.  
**TURBITES**.—1 and c, W. Harvey. 2, and he, A. Silvester.  
**DRACOONS**.—1, J. Smith. 2 and he, S. Hill.  
**ANTWERPS**.—1 and 2, J. Deakin. vhc. S. Hill.  
**FANTAILS**.—1 and 2, S. Hill. 2, J. Smith.  
**NUNS, SWALLOWS, OR MAGPIES**.—1 and he, W. Harvey. 2, G. Crookes.  
**OTHER VARIETIES**.—1, 2, and he, A. Silvester. 3, W. Harvey.

## OLD BIRDS.

**CARRIERS**.—1 and 2, W. Harvey. vhc. H. Brown, J. Smithers. Ac. J. Deakin, H. Brown, c. J. Deakin, S. Hill.  
**POUTERS**.—1 and 2, W. Harvey. Ac. H. Brown (2), G. Crookes. c. G. Crookes.  
**TUMBLERS**.—Short-faced.—1, 2, and vhc. A. Silvester. c. H. Brown. Other varieties.—1, Extra 2, and vhc. A. Silvester. 2, W. Harvey.  
**JACOBIANS**.—1, W. Harvey. Ac. J. Smith, E. Brown.  
**OWLS**.—1, G. Crookes. 2, S. Hill. Ac. H. Brown.  
**TURBITES**.—1, 2, and c, A. Silvester. Ac. E. Brown.  
**DRACOONS**.—1, W. Harvey. 2 and he, S. Hill. c. J. Smith.

**ANTWERPS**.—1 and vhc. W. Harvey. 2, J. Smithers. Ac. J. Deakin (2), J. Smithers, H. Brown. c. S. Hill.  
**FANTAILS**.—1 and vhc. W. Harvey. 2, E. Brown. Ac. S. Hill (2).  
**FANTAILS**.—1, J. Smith. 2, E. Brown.  
**OTHER VARIETIES**.—1, W. Harvey (Trumpeter). 2 and Extra 2, A. Silvester (Spangled Ice and Isabelle). Extra 3 and vhc. G. Crookes (Nuns). Ac. W. Harvey (Runt), A. Silvester (Blondinet and Bald Ice).  
**JUDGES**.—Mr. E. Hutton.

## NEWCASTLE-UPON-TYNE SHOW.

This Exhibition of poultry, Pigeons, Canaries, and other cage birds was held in the Corn Exchange, Newcastle, on November 4th and 5th. The total of entries reached 1188, forming altogether a magnificent show. The entries in the three sections numbered as follows:—Poultry and eggs, 274; Pigeons, 692; Canaries, Mules, and British and foreign birds, 222. The carrying-out of the entire Exhibition reflects credit to the Committee of Management and Hon. Sec., H. O. Blankinship, Esq. No less than fifteen silver cups and ninety gold medals, the latter of the value of £1 each, and awarded as first prizes in most of the classes, were given away. We are only able this week to publish the awards of the cage birds.

## CANARIES.

**BELGIANS**.—Yellow or Yellow-marked.—1, 2, and vhc. J. Rutter, Newcastle (2). Buff or Buff-marked.—1, 2, medal and vhc. J. Rutter. vhc. W. Pearson, Dinnington O.illery; G. Turnbull, Newcastle. Dun or Dun-marked (nearest Belgian).—1, 2, and he, W. Scott, Quay-on-Tyne. Ac. T. Dobson, Newcastle. c. W. Pearson; Hackworth & Brown, Newcastle.  
**GLASGOW DOWNS**.—Yellow.—1, T. Bruce, Shotley Bridge. 2, J. Smeaton, Tweedmouth. Ac. J. Fraser, Newcastle. 3, J. Fraser, Redhead.  
**NEWCASTLE**.—1, Clark. Buff.—1, W. Brewis, Newcastle. 2, W. Wallace, Newcastle. c. W. Wallace; R. Gilhepsy, Blaydon-on-Tyne; G. Turnbull, Yellow or Buff marked.—1, W. Brewis. 2, G. Forsyth, Spittal, Berwick. Ac. W. Wallace; J. Davison.

**NORWICH**.—Yellow.—1 and medal, R. C. Jobling, Heworth Colliery. 2, J. Baxter, Newcastle. vhc. C. J. Salt, Burton-on-Trent. Ac. J. Thackery, Bradford; R. T. Vase, Sunderland. Buff.—1 and 2, J. Baxter. vhc. C. J. Salt (2). c. J. Thackery, Yellow or Buff marked.—1, R. C. Jobling. 2, T. Cleminson, Darlington. vhc. and he, C. J. Salt. vhc. J. Baxter. c. R. T. Vaux (2).  
**CRESTED**.—Yellow or Yellow-marked.—1, C. J. Salt. 2, R. H. Triffitt, York. Ac. J. Baxter. Buff or Buff-marked.—1, R. T. Vaux. 2 and vhc. J. Baxter. vhc. C. J. Salt; T. J. Knaggs, Newcastle.

**YORKSHIRE FANCIY**.—Yellow or Yellow-marked.—1, J. Thackery. 2, W. & G. Burniston, Middlesbrough. Buff or Buff-marked.—1, Dunn & Harrison, South Shields. 2, R. Pearson, Whitby.

**LIZARDS**.—Gold or Silver-spangled.—1, J. Stevens, Middlesbrough. 2, J. Dixon, Newcastle.

**CINNAMON**.—Yellow.—1, C. J. Salt. 2, G. L. Fox, Sunderland. Buff.—1, J. Fringle, Brunel Terrace. 2, C. J. Salt.—Yellow or Buff marked.—1, W. & G. Burniston. 2, C. J. Salt. c. J. Baxter; R. O. Jobling.

**MULES**.—Goldfinch, Yellow or Buff, nearest to Canary.—1 and medal, J. Purdy, Ainsington Colliery. 2, J. Miller, Newcastle. vhc. W. White, Durham; R. McGee, Gateshead-on-Tyne. c. E. C. Jobling. Yellow or Buff marked.—1, R. Hawman, Middlesbrough; 2 and vhc. J. Baxter. c. J. Stevens; R. C. Pearson. Dark.—1, J. Stevens. 2, R. Hawman.

**ANY OTHER VARIETY**.—J. Stevens. 2, W. H. Batchelor, Whitby.  
**COMMON CANARY**.—1, T. Jamieson. 2, J. Thackery. vhc. J. Smeaton; Dunn & Harrison; Hackworth & Brown.

**GREEN CANARY**.—1, 2, and c, Armstrong & Redhead. vhc. and he, A. Ross, Newcastle. vhc. and he, J. Allison, Long Benton. vhc. M. Grey, Gateshead; T. Dobson, Newcastle. Ac. H. Bishop, Newcastle; W. Swann, Newcastle. c. E. Pearson.

**GOLDFINCH**.—Moulted.—1, W. H. Batchelor. 2, T. Cleminson. Ac. J. Leyburn, Newcastle.

**BROWN LUNNET**.—Moulted.—1, J. Dickinson, Whitby. 2, R. Pearson. vhc. J. Baxter; Dunn & Harrison; G. Stephenson, Gateshead. Ac. H. Winston, Newcastle.

**BURISH BIRDS**.—Any variety.—1 and vhc. J. Baxter. 2, R. Georgeson. vhc. W. & G. Burniston; W. Craze, Newcastle. c. J. Leyburn; R. Pearson; J. Jamieson; Knight & Spencer, Baldock.

**FOREIGN BIRDS**.—Any variety.—1 and gold medal, — Lewis, Newcastle; 2, E. Mackenzie. vhc. J. Grey; H. Howie; T. Barrow, Sunderland.

**SELLING CLASS**.—1, T. Cleminson. 2, Knight & Spencer. Ac. J. Baxter (2). Dunn & Harrison. E. Gilhepsy; J. Murray. c. J. Murray (2); J. Brown (2); J. Thackery; G. Stephenson.

The Judge was Mr. W. A. Blakston.

## THE JACOBIN.

I was very much surprised and disappointed on reading "WILTSHIRE RECTOR'S" article on the Jacobin in the Journal of the 14th of October. From what he had previously written I certainly expected some assistance from him in raising the bird to its old standard, but instead I found a wet blanket. "WILTSHIRE RECTOR" tells the Jacobin fanciers that they are all right and their birds very pretty, and then he goes off the subject and away into marking—a point not under discussion at all, and one of small importance in comparison with the shape and feathering of the bird, points in which the modern bird is so glaringly deficient that they look like half-bred beside the true old type. He thinks the mane and rose great beauties, and at the same time laments the loss of the long, thin, soft-feathered birds; but if he will think it over again he will, I have no doubt, see that such birds could not have a mane, and therefore no rose, as it requires short stiff feathers to form the mane, a vile thing to come to be reckoned a beauty; so that I cannot see that they could exist together.

I must also differ from "WILTSHIRE RECTOR" about what he calls artistic beauties and fanciers' beauties. I hold that with the old fanciers they had artistic beauty of the highest order in their eye when they formed their standards of the Pouter, Carrier, &c., as anyone may see by looking at the descriptions of the different varieties where true lines of beauty are laid down. They did not say a bird must measure so much. The

points aimed at beyond all others were elegance of shape, graceful action, and the sound colouring tastefully disposed: these are certainly not opposed to artistic beauty.

"WILTSHIRE RACON'S" proposal to give a prize for mottled birds of the old style is, in my opinion, only going a very little way in the right direction, for however good, few will, I think, rank them as equal to the soundly coloured and properly marked birds. The old Reds, which were the finest I ever saw, were gorgeous in colour—(how often I have wished I could breed Pouters of the same brilliance!)—and could not be excelled in other respects by any. If there is to be a prize given let it be for the highest style of bird in every respect, and then I will gladly give substantial support to it, and would desire no better judge than Mr. H. Weir to decide upon their merits. But as Mr. Weir shrewdly remarked that one cause of the deterioration was owing to judges giving prizes to the best in the class however poor it might be, I see no benefit in giving prizes to the least bad in a bad class; therefore if birds not fairly good came forward according to the old standard, then I would withhold the prize or prizes to another season.

In conclusion, I would only remark that "WILTSHIRE RACON'S" defence of English Owls, in which he told their admirers to stick to them, was of small importance compared to his defence of the low-bred bird now styled the Jacobin. No Owl fanciers of taste can see the foreign birds at shows, and of course see their superiority at a glance; but this is scarcely possible with the Jacobin, as, if in existence, they do not appear at shows, otherwise very little writing would be required to point out their superiority to the present so-called Jacobins.—G. UZZ.

**PHILOPHISTERIC SOCIETY.**—In addition to the Crystal Palace Show of Pigeons we would remind our country friends that this Society will hold a meeting on Tuesday evening next at the Freemason's Tavern, Great Queen Street, Lincoln's Inn, and that the Show will consist of most varieties of Pigeons; admission by introduction of a member or on presentation of address card.

## BEE'S TWENTY DAYS HATCHING FROM THE EGG.

UNDER the above heading I observe a letter in the Journal by "B. & W.," endeavouring to prove that worker bees are only twenty days in being hatched from the egg. I am sorry that I did not see Mr. Pettigrew's and Mr. Lowe's controversy to which "B. & W." refers. I think I can prove that worker bees are twenty-one days in being hatched, and this is how I will do it: When we find stock hives weighing 50 lbs. or 60 lbs. three weeks after the first swarms left the parent hive we drive out the bees and put them into empty hives. If second swarms have issued we generally unite the turnouts (as Mr. Pettigrew terms them) to the second swarms. I have swarmed a hive artificially at 6 o'clock P.M., and on the morning of the twenty-second day driven out the bees from the stock hive, and found a few dozen worker bees still in their cells, only they were ready to leave them.—A. COCKBURN, *Cairnie, Aberdeenshire.*

## BRITISH BEE-KEEPERS' ASSOCIATION.

If Mr. Pettigrew will refer to the catalogue he will find that not less than £10 in money was offered at the late Show for "the largest and best harvest of honey in the comb from one stock of bees, under any system or combination of systems," the results of which were duly chronicled in your columns.

I and many others hoped for and looked in vain to see the exhibits of 100, 200, or 300 lbs. of honey, respecting which we in the south have heard so much. Perhaps Mr. Pettigrew or some of his friends may be induced to send an exhibit of two hundred-weight or thereabouts to the next show.—E. LAUBACH CLEAVE, *Hon. Sec., 1, Devonshire Terrace, Marlos Road, Kensington.*

**BEE CASE.**—At the Quarterly Small-Debt Court, held at Aughtersrader on Monday, Sheriff Barclay on the bench, Thomas Miller sued Peter Neish for £1, the value of a hive of bees. From the evidence it appears that Miller and Neish are neighbours, and that both keep bees; that a hive of the former threw off a swarm early in July, which alighted some 10 or 15 yards from Neish's bees, which, being also on the point of swarming, attracted by the buzzing, came off and joined those of Miller. The pursuer alleged that the bees properly belonged to him, while Neish offered to buy Miller's or sell his own to the pursuers. To this, however, Miller would not agree, and Neish taking possession, the action was raised. The Sheriff gave decree for 7s. 6d. the value of Miller's bees, without expenses.—(*Scotchman.*)

**ANTS IN THE HOUSE.**—We find most useful in keeping them away is Keating's Persian powder. It must be used largely at first over tables, floor, shelves, everywhere, and then in about

a month there will be hardly any seen. Afterwards it will be sufficient to sprinkle the floors only every day, bearing in mind that the ants in London are amongst the things that cannot be got rid of permanently, but with never-ceasing care they may be kept out. I tried the meat plan, but though we caught basenfuls, we never subdued them as we have since we tried the powder.—F. W. H.

## OUR LETTER BOX.

**CANARIES' FEET COVERED WITH SCALES (Blue Bell).**—The claws and shins of birds beyond a year old mostly become scaled, which scales may easily be removed either by inserting the thumb nail or a penknife beneath the edge of the same. Operate carefully. You say "they look like corns." If there should be any accumulation underneath the feet it may, perhaps, be caused through dirt gathered from the cage bottom. If so wash the feet gently in some lukewarm water, which will soften the substance, and with the aid of your thumb and finger relieve the feet from the dirt.

**RABBIT ARRANGEMENTS (Mars).**—We see no objection to your proposed arrangements, nor could anyone advise not knowing the place. The dog you mention is probably only changing its coat. If there is any redness of the skin wash the dog with soft soap and water. Give more exercise.

**PRESERVING HIVES AND THEIR COMBS (A Bee-keeper).**—Your hives of combs for swarms next year should be placed or hung up in a dry place where mice and moisture will not injure the combs. In a moist place, such as a room with damp walls, the combs would perish—that is to say, lose their adhesive properties, and be useless for swarms. We preserve all such combs in a garret.

**REMOVING HIVES (J. P., jun.).**—Far better let them winter where they are. In the transfer now to your "cold-house farmery," would cause the sacrifice of many lives among your bees, of essential importance to their well-being. The gain, if any, would not compensate for the loss. Thatch warmly and trust to Providence.

**BEE-KEEPING NEAR LONDON (Ignoramus).**—1, Your bees would certainly find their way home after a day's work, in spite of the enclosed situation of your garden. 2, In an ordinarily good year they would be likely to afford you a margin of profit we doubt not. They would go beyond the limits of the garden you speak of. 3, Mignonette, borage, laurustinus, thyme of all sorts, garden fruit trees are all productive of honey. Of the two former a good succession should be kept up. But trust rather to the forage they would get beyond.

**QUINCE MARMALADE (G. Haddington).**—We did not receive the letter you mention. Gather the fruit when fully ripe and of a fine yellow; pare, quarter, and core it; put the quinces into a saucepan with a little water, and set them on the fire until they are quite soft; then take them out and lay them on a sieve to drain; rub them through and weigh the pulp; boil an equal quantity of sugar to *petite case*, then add the pulp, and stir them together over the fire until it will fall from the spoon like a jelly. The marmalade is then fit to be put into pots, and when cold cover them closely.

## METEOROLOGICAL OBSERVATIONS.

## REMARKS.

3rd.—Very dull dark day, much warmer, and but little rain.  
4th.—Hazy early; fine till 2 P.M., then cloudy, with a little rain; fine night.  
5th.—Fine till noon, after which it was damp and very dark.  
6th.—A great fall in the barometer during the night; a very stormy morning, occasionally bright, but on the whole a stormy day, and the wind very high.  
7th.—Most beautiful day, but rain commenced about 8 P.M., and it fell heavily at midnight.  
8th.—A fine day throughout, but particularly fine in the morning.  
9th.—Hazy all the morning, and showery from noon, but the rain not heavy; great rise in the temperature during the day, having changed from 35° at 9 A.M. to 50° at 9 P.M.  
Both the barometer and the temperature very variable, and at times rapid in their changes. The mean temperature 2° above that of the preceding week, and the maximum in sun exceeded that of last week by 15°.—G. J. SYMONS.

## COVENT GARDEN MARKET.—NOVEMBER 10.

THERE are no quotable alterations in the supplies, and prices remain substantially the same as last week.

From observations taken near London during forty-three years, the average day temperature of the week is 43.5°; and its night temperature 38.9°.

## STRAWBERRY CULTURE—DUC DE MALAKOFF STRAWBERRY.

**S**ELDOM (and rarely honourably) mentioned by our distinguished fragarians is Duc de Malakoff Strawberry. Gratifying indeed it is to find the author of the "Fruit Manual" pronouncing it to be "a very excellent Strawberry," exactly what I have found it in a light shallow soil, which can only be made to grow Strawberries by heavy manuring, in the soil and on the surface. "O. P. P."

Dr. Roden, and others may raise a cry when a departure is made from the system they consider orthodox. Their soil suits the Strawberry so well as to render frequent renewal unnecessary. In fact, I knew a gardener that had Strawberries on the same ground without renewal of plants for over twenty years, and relied upon them (Roseberry) for the supply of preserving fruit. True to his faith (and it were that of a veteran, he having had over fifty years' experience of Strawberries in that soil and place), a futile attempt was made to grow British Queen upon the same system. What, however, with Hautbois run wild, Keens' Seedling, Myatt's Seedling (Filbert Pine), and Elton, really passable fruits were had for dessert and "loads" for preserving.

Different indeed is my practice and soil. His was a strong unctuous loam; mine is a light shallow one, which may not be stirred deeper than a foot or 15 inches. With this latter kind of soil I have at present to do, and, as there is much of a similar kind, a short account of my experience and practice may not be uninteresting. The plants bear the finest fruit the first year, more of it and smaller the second, and in the third season a very moderate crop of inferior fruit, amounting to a waste of land, material, and labour. After the second year the plants either go off—plants here and there—leaving ugly gaps, or become superabundant only of foliage—sterile so far as fruit is concerned. Placing between every alternate row of plants a year old, and fruiting for the first time, a row of 3-inch pots filled rather firmly with good loamy soil, as closely together as they will stand and level, the first runners are laid upon the pots, one in the centre of each, and secured with a wire pin, like a hair pin, cutting off the bine beyond the first runner—the only one layered. Early in July there will be sufficient runners to fill the pots, as we have the choice from the runners of two rows of plants, the pots being placed in alternate rows, and a row is left clear for facility of gathering the fruit without danger of injuring the layered runner-bines. If dry weather ensue water every other day, whilst, if moist weather, watering will not be necessary. In a fortnight the runners will be well-rooted, and within that and three weeks they should be detached from the parent, for if left longer the roots become matted in the pots, and before that takes place they should be planted out. Early Potato-ground will be clear or other crops off, as Peas or Cabbage, and all the preparation given is to manure well and dig in deeply; or if the ground be in good heart

the manure is not always given, but merely dug. The plants are put out in rows 2 feet asunder for the compact growers, as Keens' Seedling, with the plants 1 foot apart; the stronger kinds, as President, require the rows 2 feet 6 inches apart, and the plants 15 inches apart, watering in dry weather until established, and keeping clear of weeds and runners as they appear. In October or early November a mulching is given at least 2 inches thick of short but very rotten manure between the rows and plants, placing near the crowns, but not upon but beneath the leaves. No implement of any kind to be used in the spring and early summer after planting for loosening the soil or removing weeds, for it wants solidification, and this the feet will do in removing weeds; and in a firm soil the Strawberry and everything else is much more fibrous-rooted than in a loose and open soil. Water as much as you like between the rows after the fruit is set and swelling freely, remembering that a good soaking once a-week is worth a surface-wetting every day; but I do not water, and the fruit is always large enough, and it is "big 'uns" we want and have.

Well, we have a heavy crop of course, and have secured what runners are required for planting and forcing, and we cut up every other plant in the rows and clear the other of runners, making all neat and trim. Weeds and runners only trouble us further until autumn, and then in October or November comes the top-dressing as a year previously with short about half-decayed manure, and the following season we have a heavy crop, and clear them off the ground after fruiting, and crop with any winter greens we want. We plant about half the ground under Strawberries every year, and have in return plants a year and two years old, longer than which it is not profitable to continue them. The one-year-old plants will be the staple for dessert, whilst the two-year-old will give some for that purpose and later, and an immensity for the still-room or preserving.

The laying in pots may be considered a trouble, but it is not too great for plants intended to perfect their fruit in pots, and why should a little extra trouble be grudged over those intended to be fruited in the open air? or is not a crop of fruit the first year equal to what is gained from plants left to root as they may, planted some time in summer or autumn, will give the second year, worth striving for? Late planting of self-rooted runners in any soil means loss of a year's crop; for in a strong soil, as in a light, early-planted early-rooted runners will give their finest fruit the first year. Another plan which answers well with me is to plant out the plants which have been forced in rows 2 feet apart and 18 inches asunder in the rows. They never fail to fruit heavily the following season, after which they should be cleared off. I have, however, kept them a second season with satisfactory results.

Runners are never taken of plants other than those fruiting, thereby securing fruitful plants. Any not showing fruit should be rooted out and replaced by fruitful plants from pots, which is easily done when plants are forced. If laying in pots be an objection strips of

turf, cut 4 inches wide and 3 inches deep, laid between the rows grass-side downward, the runners pegged to the centre 4 inches distance apart, and in three weeks cut equidistant between the plants, and planted they are as good or better than from pots. Or if turf may not be had, firm the soil between the rows, every other only, and peg the runners 4 inches distance apart, a row up the centre, and in three weeks thrust a trowel all around each plant about 2 inches from it and lift with a ball, planting and watering well, and little check will be experienced.

The kinds I have reduced to are Keens' Seedling—that form of it and Sir Harry some time since going as Hooper's Seedling, which crops heavily; it is very dark in colour when fully ripe, ovate in form, and in large fruit cockscomb-shaped. I have had fruit of it 2 ozs. in weight and ten and twelve to a pound. This Keens' Seedling, still for all purposes unsurpassed, is our first early, and never fails, but is good for nothing after the second year.

Black Prince I have let die-out, for though it cropped heavily its size was objected to. It does exceedingly well in light soil, giving nice early fruit for dessert and abundance for preserving.

Sir Joseph Paxton is the handsomest of all Strawberries, and excellent.

La Grosse Sucrée is free in growth and bearing, not unlike Duc de Malakoff, but inferior to it for flavour. Of Sir Charles Napier we retain a few, also Oscar, but few they will remain.

Duc de Malakoff follows Keens' Seedling, preceding or with President, and is of a dwarf compact growth, and, considering the size of the berries, prolific. The fruit is very large, cockscomb-shaped if the fruit be at all large, good specimens being frequently 2 ozs. weight (I have had some close upon 4 ozs.), eight and ten to a pound—in one instance six, and though monsters, they are not coarse, or hollow or flavourless; for it is a characteristic of this kind that the fruit, however large and when forced, is always high-flavoured, surpassed by none except British Queen, and approached by no other large kind except Frogmore Late Pine. From its very dark-red colour it is not a showy fruit, and the colour pervading the flesh, as well as externally, is not by some liked; but as fruit is grown to be eaten, its juicy, sweet, and rich flavour will overcome objection to colour.

President, though a strong grower, crops well, and stands wet uncommonly well; but drought in close quarters causes it to mildew. The fruit is large—ten and twelve to a pound in good examples; the heaviest I ever had weighed 2 ozs., and many 1½ and 1½ ozs. Taken all in all it is the best of all Strawberries for a light soil and for forcing.

Lucas, with its dwarf compact growth, fine fruit, and free-bearing, is one of the very best; but it and Duc de Malakoff occasionally have the plants going off from canker, also Dr. Hogg, which is not, however, serious, unless the plants are continued beyond two years.

Hélène Gloede I have added, in view of a late kind superior to Frogmore Late Pine.

To weed-out for a light soil I would leave—1, Keens' Seedling, with a few La Grosse Sucrée and Sir Joseph Paxton; 2, Duc de Malakoff for its size and flavour; 3, President; 4, Lucas; and 5, Hélène Gloede; and to still further reduce to two, Keens' Seedling and President, which for general usefulness are not yet beaten.—G. ARNBY.

### HARDY HEATH CULTURE.

Or these there are now rather an extensive collection, and among them are some of great beauty. All are interesting, even the common *Erica vulgaris* when seen in quantity as on the mountains and moors about the month of August, imparting a rich purple glow to all around. *Erica cinerea* and *E. tetralix*, with their bell-shaped flowers, furnish us with a pleasing diversity to the vulgaris section, while the *Menziesias* are charming evergreen shrubs of low stature, worthy of more extended cultivation, and which cannot fail to please any who may commence their cultivation. The cost of these plants is very trifling, and they are easily procured with the exception of *M. cærulea*, which is rather rare. *M. polifolia alba*, *M. p. atropurpurea*, and *M. empetrifolia* (the last-named being of dwarf habit) are very suitable for making individual beds or planting as edgings to beds of *Rhododendrons*, *Azaleas*, or, in fact, any of the peat earth plants; or if planted in connection with rockwork they are of rare beauty, and are invaluable for such work. All are of easy culture, not requiring after being carefully planted any special attention.

No doubt the native soil of the hardy as well as all other Heaths is peat, but, to those unable to procure such, a soil can be made up to grow hardy Heaths perfectly if leaf or any other well-decayed vegetable mould can be procured, and to this add about an equal quantity of any ordinary free garden soil, with a fair sprinkling of sand to allow the moisture to penetrate freely into the soil, and prevent it from becoming hard, sodden, and sour, as it would have a tendency to do if no sand were used. The plants will flourish in such a mixture in the greatest luxuriance. I have always found that it was of the greatest benefit to them to have an annual top-dressing of about 2 inches of leaf mould, which not only assists in preventing excessive evaporation, but supplies the plants with an ingredient into which their tender and hair-like roots run with the greatest avidity. If it is desirable at any time to increase the stock nothing can be more simple: merely add more sand to the existing leaf mould, into which peg the shoots, when they will very soon emit roots in abundance.

The winter-flowering properties of *E. herbacea carnea* very properly make it an especial and general favourite, while the varieties of *E. vagans* are best for autumn-blooming—indeed, almost the whole season some of the species are in flower.

I name a few of the various sections that I consider specially worthy of cultivation in addition to those named above:—*Ericas vulgaris alba*, *Allportii*, *aurea*, *coccinea dumosa*, *Hammondii*, *rigida*, *Searlei*, *Lawsoniana*; *E. cinerea*, varieties *alba*, *atropurpurea*, *coccinea*, and *rosea*; *E. tetralix*, varieties *alba* and *rubra*; *E. vagans*, varieties *alba*, *carnea*, and *rubra*, as well as *E. ciliaris* and the varieties of *mediterranea*.—J. B. S.

### ROSE ELECTION.—No. 2.

The following lists show how the electors voted:—

Mr. HENRY CURTIS (Curtis, Sandford, & Co.), Devon Rosery, Torquay.

- |                             |                          |
|-----------------------------|--------------------------|
| 1. Marquise de Castellane   | 13. Princess Beatrice    |
| 2. Capitaine Christy        | 14. Paul Néron           |
| 3. Louis Van Houtte         | 15. Madame Berard        |
| 4. Comtesse d'Oxford        | 16. Madame Nachury       |
| 5. Ferdinand de Lesseps     | 17. Hippolyte Jamain     |
| 6. Catherine Mermet         | 18. Reynolds Hole        |
| 7. Mdlle. Eugénie Verdier   | 19. Jean Ducher          |

### URCEOLINA AUREA (PENDULA).

VERY pretty are the bright golden yellow flowers, beautifully tipped with green, of this plant in October, produced, as they are, in an umbel 9 inches to a foot in height, from which the flowers (seven) droop in a very graceful manner, the flowers following each other—seldom more than three being fully developed at the same time. The flowers are produced before the leaves, those succeed them: hence the plant requires to be kept moist and in a light position during the winter months—in fact at all times; the leaves are not unlike those of the Eucharis, but smaller. Urceolinas only require to be duly supplied with water during growth, withholding it when the

leaves commence turning yellow, and during rest water is required only to keep the soil moderately moist. Ours have no water given them, but the pots are placed where they are subjected to a damping overhead twice daily, and the soil does not at any time become dust-dry. I am no believer in Carlyle's term, "dry as dust" applying to bulbs, or anything else when at rest, or only to those which, in their natural habitat, have considerably more warmth than is afforded them in a cultivated state; for if they do not grow they mature, and we give complete dryness as an equivalent for the greater warmth and some moisture of the torrid zone during the resting period.

Urceolina aurea is a stove bulbous plant, but will do well in an intermediate house, in a cool stove, or warm greenhouse, and a 6-inch pot is sufficiently large for it, with efficient drainage, and a compost of turfy yellow loam three parts, one part each leaf soil, old cow dung, and silver sand. Potting is best done when the plant is in free growth, as it roots freely some time before throwing up the flower stem.

Propagation is effected by offsets, which may be removed at the time of potting, putting each in a pot separately, and of about three times the diameter of the bulb. The bulbs do not quickly arrive at a flowering size. The flowers of this plant are very ornamental, coming in at a time when flowers are scarce.—G. ABBEY.

### PEACH CULTURE—ESTIMATE OF SORTS.

THE culture of Peaches on open walls has been attended with so many failures, even in the most favourable localities, that it has long been regarded as a very speculative affair upon which the most skilful practitioners enter with a certain amount of hesitation. An immature wood-growth, gumming, canker, mildew, curled and blistered foliage, attacks of aphides and red spider, are the chief evils affecting the health of the tree; untimely wet and cold weather are those which are most hurtful to the crop. A strong conviction of the prevalence of much ignorance of the best means of combating these evils, induces me to prefix the estimate of such kinds as are most worthy of notice, with a few brief cultural hints not given fully in former papers, and which are of the highest importance.

IMMATURE WOOD-GROWTH.—Regarded superficially, this evil might be said to arise from a cold dull autumn or the tardy falling of the foliage; but there are other influences often at work very early in the season of growth which affect it much more seriously than the declining temperature of autumn. As the tender spring foliage unfolds itself aphides may frequently be found attacking it, almost singly it may be at first, but swelling to countless numbers with surprising rapidity. The foliage then soon becomes contracted and curled, the growth crippled, stunted, and checked so severely that it often makes very little way till midsummer, and then, unless an unusually favourable autumn ensues, the remaining season of growth is too brief to admit of its becoming thoroughly matured and ripened. A close watch must therefore be kept, and the foliage cleansed from its insidious enemy before it has time to do much mischief. Do not wait till the foliage is curled and the growth crippled, but be prompt in applying the remedy which Nature has provided ready to your hand. Syringe with clean water, follow this with a sponge and more clean water, examining and sponging every foul leaf, then repeat the syringing, taking care to well wash every part of the tree. This is a somewhat tedious operation at a busy season of the year, but it is most effectual and sure. I had to do it repeatedly in the spring and summer of the present year, and am well rewarded for my pains with a fine, strong, clean growth, firm in texture, ripened to the tips, and full of promise for another season. Winter dressings may destroy such insects, eggs, or larva as are deposited in the joints and angles of the branches, but I never have found them quite effectual as a preventive of summer blight, and do not advise them for healthy young trees in full vigour.

The foliage when young is as sensitive and delicate as the flower petals, and sustains much injury from the least exposure to cold east and north-east winds. Let me give an example of this. A fine young tree of Dr. Hogg Peach, planted in a snug corner against a south wall, with a viney sheltering it on the east side, had its foliage so much affected by blister and curl in the spring of 1874 during the prevalence of a north-east wind, that the growth became swollen, crippled, and stunted so much as to affect it for the entire season. I must confess I was puzzled for a time. There was the tree in one of the most sheltered positions in the garden, especially guarded

from the cold wind by which it was evidently affected. I at length came to the conclusion that the cold air, driven with great force upon the roof of the vinery, must then dash off downwards at an acute angle, as one sees rain do—hence the mischief. A wooden screen was then promptly fastened upon the end of the vinery, and a permanent and effectual check given to the “scathing blast,” which since then has done no harm, this tree being especially remarkable now for its fine foliage and strong growth.

Having secured a healthy vigorous growth from spring till autumn, the next point of importance is to remove the foliage as soon as its hold upon the branches becomes loosened. It has frequently been advised to do this with a broom, but I must confess I do not like such rough practice, and more especially when the work is entrusted to boys, as is frequently the case; for I am convinced that the trees may then be so much bruised as to induce canker, gumming, and premature decay. I like to remove the foliage gradually and carefully, so as to admit air and light among the branches to harden the sensitive outside before it is fully exposed. So important do I consider this, that I contrive, if possible, to pass a soft hair-brush over the trees every day or two after the leaves begin to fall till the branches are quite bare. Depend upon it we cannot be too tender in handling the shoots and branches. If greater attention were given to this now and when the pruning and training is done, canker and gumming would be much less common than they are at present; not that I would infer that bruises are the sole causes of these evils, for I have shown in former notes how it is possible for frost or hot sunshine to do much mischief.

**MILDEW.**—This may arise from drought, and also from superabundant moisture, such as the stagnant water of an undrained border. Either cause bears its remedy upon its surface, and I have no need to dwell upon them. There is, however, another source from whence this pest springs, and spreads with greater rapidity and more deadly virulence than from any other, and this is when blood or carrion of any kind is used as a stimulant for the roots. Some years ago I had Peach trees destroyed by mildew induced solely by pouring fresh blood in a trench opened upon the roots. I could also tell of Grape Vines, famous for the splendid annual crops which they had borne for a lifetime, being ruined when they passed into fresh hands by an attempt at renovating the border with garbage from a slaughter-house. Never use fresh blood or carrion as a manure; mix it with soil, let it decay, turn the heap repeatedly, keep it for a year, and it will then be more valuable than guano—perfectly safe, sweet, and free from all those crude substances which are so unwholesome and dangerous.

I append a note of a few select kinds placed in the order of ripening, and invite discussion. It has been said that the Peach has no literature; let us make one for it in the pages of the Journal.

**Early Beatrice.**—This has fruit of medium size, bright red on the exposed side, of a pleasant, agreeable flavour, but not rich. It is one of our most valuable Peaches, ripening early in July. The tree is moderately vigorous.

**Early Rivers.**—A fine and distinct variety, closely following Early Beatrice. The fruit is large, of a pale straw colour with just a tinge of pink, and of most delicious flavour. I have observed a tendency to stone-splitting in one or two fruits, but have not found the bulk of the fruit so affected. The tree is remarkable for its wonderfully vigorous growth and the manner in which the strongest shoots are furnished with triple buds, so that the new and absolutely rampant growth is really splendid—plump, well-ripened, fruiting wood for next season.

**Rivers' Early York.**—The fruit of this is very handsome, round, smooth, and beautifully coloured, of a clear bright red, occasionally mottled. It is large, and produced in great abundance. The growth of the tree is remarkable for its short-jointed wood and close compact habit, presenting a striking contrast to the rampant vigour of Early Rivers.

**Dr. Hogg.**—A distinct and valuable variety. The fruit is large and very handsome, the colour being a brilliant deep red, and so beautifully mottled with lighter shades of the same colour that it invariably attracts attention; nor does it thus attract simply to disappoint, for the flavour is sweet, rich, and excellent. The tree is vigorous, and the deep green foliage is unusually large and handsome.

**Grosse Mignonne.**—A fine old Peach, very prolific and good, quite one of our best midseason varieties. So highly do I value it, that if I were asked to recommend one kind as the best for an amateur, this would certainly have the preference.

**Noblesse.**—This is a splendid kind. The fruit is very large and handsome, and the flavour so delicious that to call a new Peach equal to it in this respect is to give it the highest praise in one's power. The tree is a somewhat delicate grower, but is perfectly healthy under good treatment.

**Belle Baucé.**—A very fine Peach, with large handsome fruit of a deep red colour and of delicious flavour. One does not often meet with this variety, and yet it is most worthy of a prominent position in every collection, the fruit invariably attracting attention by its fine form and beautiful colour. The tree is healthy, but it is only moderately vigorous; and this may in some measure account for its being so little known.

**Barrington.**—An excellent autumn Peach. The fruit is large, somewhat elongated, and is remarkable for its point or nippie, which is very prominent. It is highly coloured, of a deep red, is excellent in flavour, and continues good late in October.

**Walburton Admirable.**—A favourite autumn sort, and deservedly so. The fruit is large and of most delicious flavour, pale yellow in colour, with a tinge of red on the exposed side. It has been termed a shy bearer, but I have found it a most abundant cropper. The tree is very healthy and vigorous.

**Lord Palmerston.**—This is a very late kind, bearing magnificent fruit quite a foot in circumference and most brilliant in colour, but it does not ripen well on an open wall. Its fruit surpassed all other kinds in size and appearance this season, but none of it ripened thoroughly. It was, however, most useful for stewing.—EDWARD LUCKHURST.

## HERBACEOUS PLANTS FOR BEDDING.

ON reading your reply to “A. M. G.” in the Journal for 7th of October I thought it needless to trouble you with any remarks, the subject for consideration being so very limited in its range—viz., the selection of some hardy herbaceous plants of the same height, and to bloom at the same time, as Geraniums; and I could not help agreeing with your implied opinion that there were no such plants in existence. Even now I believe we have yet to discover a hardy plant equal in all respects to the usual summer bedders in duration and profusion of bloom.

But as it appears to me that the object of “A. M. G.” in common with many other amateurs, is to reduce the trouble and expense of keeping tender plants through the winter and of propagating them in heat in the spring, I do not know of any reason why we should confine our attention to hardy herbaceous plants exclusively, there being many available subjects, easy of culture and showy in their foliage or their bloom, that may be raised from seeds or increased by cuttings, and needing only the protection of a cold frame or temporary shelter from severe frosts and continued heavy rains.

I am in doubt whether it is proposed to mix hardy perennials and Geraniums in one bed, or merely to have separate but corresponding beds of each, but this is a matter of detail; and although there are few hardy plants which would associate well with such sprightly companions—and I should advise separate beds of each kind wherever practicable—a hint may be taken, on the other hand, from a chaste and favourite combination often seen in the public parks—a mixture of purple *Violas* and silver-leaved *Geraniums*.

The *Clematis*, though not herbaceous, is hardy and perennial, and may remain undisturbed for years. Two varieties planted alternately, 2 feet apart, one for spring and one for summer and autumn flowering—say *C. Standishi* and *C. Jackmani*—will give a long and nearly continuous succession of bloom of rich blue and purple hues, and may be pegged and trained to any height required. Plants may be turned out of pots at any time when the weather is open, and there is no time like the present. They should not be pruned for this mode of culture, except so far as may be necessary in cutting away the dead wood and to prevent confusion. The bed should be well dug and heavily manured, mulched in June with 2 inches of half-rotten horse or cow dung, and supplied with liberal doses of liquid manure in dry weather. When the flowering is over and the shoots have ripened, dwarf evergreens may be plunged in pots between the stools and will give an agreeable change. About the middle of March the pots must be removed, and the holes filled-in with very rich fresh soil to meet the insatiable appetite of these *Clematises*. If a live edging be considered desirable for this bed, try *Santolina incana* or *Cineraria maritima*, or any hardy plant of a stiff dwarf habit having white or golden variegation in its leaves.

The Tom Thumb varieties of the *Antirrhinum* grow about

12 inches high, and with careful stopping of some of the shoots give a long succession of bloom. Seed may be had mixed, or in several showy and distinct colours. Grow the seedlings till they flower and then take cuttings, keeping them named and separate as with other bedding plants. Perhaps plants may be procurable; if so a season would be saved, the expense being of course greater. Both the Clematis and Antirrhinum like a little chalk or old mortar mixed with the staple soil, but the Snapdragon requires no manure whatever, and might be grown almost without any soil at all.

The Viola, in moist rich soils, and in all but very dry seasons, is a capital bedding plant, including as it does colours not seen in the Geranium family, and its height never exceeds a foot. None of the sorts can be depended upon to come true from seed, but mixed beds from seed of *V. Perfection* and *V. lutea grandiflora* will give a pleasing variety of purple, yellow, white and intermediate shades. The seed should be sown in a warm house, the seedlings hardened off, and planted out in May, when bloom will soon appear and will probably continue far into the autumn. Cuttings of named varieties struck in August will flower early in the year, and old plants divided in spring will give a succession of bloom for the later months. The Viola is perfectly hardy, but unless it has frequent change of soil soon degenerates into insignificance.

*Pyrethrum Prince Arthur* is an improvement on the old double white *Pyrethrum*, being dwarf and free-flowering. Plants from cuttings do not attain a greater height than 12 inches, and bloom profusely all the season. I have tried these cuttings in the open ground, but on the return of spring their place was vacant; and the cold frame is therefore their proper home during the winter. *Pyrethrum Golden Gem*, a new variety of the well-known *Golden Feather*, has small double white flowers which last for many months if the seed be sown early. The foliage is similar to, but not nearly so good as, that of the *Golden Feather*, and becomes rusty when the flowers appear. This comes quite true from seed, and is about 12 inches high when full grown, and is good for a mass where white and yellow are wanted, but as an edging we have no occasion for it.

*Tom Thumb Tropaeolums*, sometimes called *Nasturtiums*, have showy and lasting blooms of many rich colours, and in poor soil they make quite a blaze. Their culture as hardy annuals is too well known to require comment, but cuttings are generally taken when it is desirable to keep the stock true.

*Tagetes signata pumila* has lately been aspiring to the proud position hitherto held by the *Calceolaria*; the latter, however, still holds its ground in rich soils, and may be kept through the winter without fire heat. The *Tagetes*, on the other hand, does better in poor, light, or dry gravelly soils. It is a half-hardy annual with bright yellow flowers, grows from 9 to 12 inches high, and may be raised from seed in the spring as advised for *Viola*.

There are other plants I might mention, but space forbids any further extension of these notes. Those plants I have named need as little attention, and give as little trouble to grow, as we can expect with cultivated plants that would, if neglected, be overrun in one season by our native weeds, or become weeds themselves.

Before closing I should like to add that by leaving herbaceous plants in the beds we invite bare earth and desolation for several months in the year; therefore clear and dig the beds and plant or plunge evergreens, or bulbs, or spring-flowering perennials, or all three, and you will avoid the horticultural bugbear of the age, and help to fill up the dreadful gap in the floral cycle which is almost universally met in places devoted to summer-bedding. Variety and change are in small gardens essential to the happiness of the proprietor and to the enjoyment of friends and neighbours.—F. B. Blackheath.

#### NOTES AND GLEANINGS.

At the meeting of the Metropolitan Board of Works the week before last, it was resolved that the Works Committee should consider the desirability of taking steps for applying to Parliament in the next session for obtaining the FEE OF THE CHELSEA BOTANICAL GARDENS belonging to the Apothecaries' Company, and that the Solicitor to the Board be instructed to give the necessary notices.

We are informed that Mr. Wills, with a generosity that does him credit, gives the GOLD MEDAL which was awarded by the Council of the Royal Horticultural Society for the new

*Dracasnas* to his foreman Mr. F. Bause, and Mr. Wills has given instructions that the inscription be appropriate to Mr. Bause's acceptance of the honour. This is a graceful recognition of the successful hybridist's valuable services.

It is a common opinion that the GUANO on the Chincha Islands is an accumulation of excrements of the thousands of birds swarming there. This is only partly the case. The upper stratum, and much the less, consists of the excrements and remains of birds, as also the excrements and remains of seals (*Otaria*) frequenting the island. The lower, and much larger mass, has been formed in prehistoric times, through the sinking to the sea bottom of excrements of numerous birds that confined themselves to a small region of the sea; thus were produced layers which afterwards were raised with the sea bottom and formed the islands. This mode of deposit of guano is still going on.—(*Chemisches Centralblatt*.)

SOME interesting observations have lately been made by M. Nobbe on the ROOT FORMATION OF SOME OF THE CONIFERS. If seeds of Silver-leaved Fir (*Pinus Picea*), Spruce Fir (*P. Abies*), and Scotch Fir (*P. sylvestris*), be placed in sand which is supplied with a nutritive solution, there is found to be the greatest difference, at the end of a year, in formation of roots by the three. Thus the Spruce Fir had nearly double the number of root fibres of the Silver-leaved Fir, while the Scotch Fir had twenty-four times as many. Similarly, as regards length of root, one year's root-product of the Spruce was double in length that of the Silver-leaved Fir, and the Scotch Fir roots were even six times longer than those of the Spruce, and twelve times the length of the Silver-leaved Fir. As regards above-ground vegetation, the entire surface of the parts, in Spruce, Silver-leaved, and Scotch Fir respectively, was 100, 107, 297, so that the much greater development of the Scotch Fir is here also apparent. It is well known how this tree maintains a large body on small supplies of nutritive material, and how it thrives where Silver-leaved Firs succumb. Even at six months' age it rules a space of ground which ideally may be considered as an inverted cone of 80 to 90 centimetres in height, and nearly 2000 square centimetres of base-surface. The foregoing facts also throw light on the difficulty of transplanting Scotch Firs, a considerable portion of the roots being generally left behind.—(*English Mechanic*.)

ONE of the most important of the late discoveries in chemistry is that made by Professor Mantogazza, of Pavia, that OZONE is generated in immense quantities by all plants and flowers possessing green leaves and aromatic odours. Hyacinths, Mignonette, Heliotrope, Lemon, Mint, Lavender, Narcissus, Cherry Laurel, and the like, all throw off ozone largely on exposure to the sun's rays; and so powerful is this great atmospheric purifier that it is the belief of chemists that whole districts can be redeemed from the deadly malarial which infects them by simply covering them with aromatic vegetation. The bearing of this upon flower culture in our large cities is also very important. Experiments have proved that the air of cities contains less ozone than that of the surrounding country, and the thickly inhabited parts of the cities less than the more sparsely built, or than the parks and open squares. Plants and flowers and green trees can alone restore the balance; so that every little flower pot is not merely a thing of beauty while it lasts, but has a direct and beneficial influence upon the health of the neighbourhood in which it is found.—(*Sanitary Record*.)

THE following gentlemen have consented to act as Judges at Messrs. James Carter & Co.'s Annual Root Show to be held at the Agricultural Hall on November 18th and 19th. Mr. James Brebner, Her Majesty's Norfolk Farm; Mr. A. Blake, Heythorpe Park Farm; Mr. William Brignshaw, Her Majesty's Bagshot Park Farm; Mr. E. W. Booth, Trent Park Farm. Captain Walter of Tangley, Berks, has also consented to act as referee.

LATE STRAWBERRIES.—On Saturday, 30th of October, upon the same stall as before in Nottingham Market (see page 358, October 21st), were exhibited by Mr. Joseph Lamb of Burton Joyce two more fine baskets of Strawberries, even finer than before, and gathered under the same conditions. This I think may be considered the latest date that ripe Strawberries have been gathered from the open field without protection, and considering the cold wet weather we have lately experienced makes the fact the more remarkable; and had the plants been prepared by taking off the first crop when in flower most likely the crop would have been more remarkable still, and shows what might be done with this useful sort—viz., the Vicomtesse

Héricart de Thury, so called; properly I believe the Marquise de la Tour Maubourg, and worth recording.—S. T.

### STAPELIAS.

Of late years the public taste has been of a somewhat advanced type in floricultural matters, and many old favourite garden plants have been forgotten or greatly neglected. In the period preceding the rapid and ever-increasing stream of new varieties of popular flowering plants hothouses were filled with plants which are seldom met with now. Amongst these were the Stapelias. We once found them almost everywhere, but we now seldom see them except in collections where succulent plants are still cherished. There is, however, a visible change in the taste for flowers at the present day, and beauty of form is receiving attention, as well as colouring and the amenability of a plant to rapid propagation. This is seen in the increased demand for succulent plants, which have risen so rapidly in public favour.

Plants which are quaint and distinct in habit are now being sought after, and well are they worthy of the search. The rich collection of these plants at Kew never had so many admirers as they have now, and the noble assemblage of them in the houses of Mr. Peacock at Hammersmith have a greater value in the horticultural world than they ever had before. This gentleman is entitled to the thanks of all lovers of rare and curious plants by the preservation of his collection, and especially for his liberality in placing a contingent from them for public enjoyment at the Alexandra Palace. This extremely valuable loan to the public will do much to popularise these curious plants, and Mr. Peacock even now has a reward in finding that his plants are greatly admired and his generosity appreciated.

The Stapelias are succulent plants from the Cape of Good Hope. They are grotesque in form, and the flowers of many of them are singularly beautiful, but they emit a carrion-like scent. So powerful is this odour that the common blow-fly is deceived by it, and will often deposit eggs in the flower, as if mistaking it for decaying animal matter.

These plants are easily propagated by cuttings or branches, which should be inserted in April, keeping them dry for a week, and then carefully watering them. After the plants are rooted they are best placed in the open air in the full sun, affording them a hot sheltered position. In September they must be placed under glass, and during the winter months they cannot have too light a position. Many succulent plants are ruined by storing them away in dark and unsuitable places during the winter months. In the winter they do not require water, but they do require every ray of light that can be afforded them. In the summer they need to be watered freely. The soil best suited for them is three parts of sound loam and one part of broken bricks.

The species are very numerous, but all of them are curious and ornamental both in habit of plant and form and colour of the flowers. *S. variegata* is one of the most striking, the flowers being pale yellow veined with brown. The engraving, fig. 95, gives a truthful representation of this singular family of plants.—J.

### THE PEAR-TREE SLUG.

The current number of the "Entomologist" contains a life-history of the Pear-tree slug from the pen of its editor, extending to nearly eleven pages of that journal. It is very notable that the history of this annoying and almost disgusting enemy of the orchard was first studied in America, where Professor Peck prepared a valuable memoir, which was published at Boston, and received a gold medal with fifty guineas in cash. This was nearly eighty years since, and subsequently a portion of this memoir was introduced by Harris into his "Treatise on Insects Injurious to Vegetation." Some slight account of it, however, had been given by the illustrious Réaumur, and other continental observers followed in his wake, while in our own land Professor Westwood has chronicled various particulars. As we learn from Mr. Newman's life-history now before us the identity of the English with the American species is questioned by some, the habits at least show a marked similarity. Our author does not debate the point whether there is any truth in the assumption that the slug reached us from America. The native tree, Mr. Newman asserts, is the Sloe. In some districts near London this season it appears to be taking extensively to the Hawthorn hedges, which are much to be pitied, seeing they are so liable to the attacks of insect enemies of several orders. From the

Fig. 95.—STAPELIA VARIEGATA.

article referred to we extract a paragraph or two of special interest. Concerning the imago or perfect fly (*Blennocampa Pyri*), it is merely necessary to state that it belongs to the group of the saw-fly. The head, antennae, body, and legs are a dingy black, and a streak of that hue crosses the transparent wings. Upon the least alarm the insects feign death, and folding themselves together drop to the ground. The females make an abrasion on a leaf or leafstalk with the saw; and the egg, as occasionally happens amongst insects, has an elastic shell, allowing of expansion ere the grub emerges.

Concerning the grub or slug Mr. Newman writes: "They are first observable at the beginning of July, then of course very small, and a succession continues to make its appearance throughout August and September, and even far into October. They glide with extreme slowness over the surface of the leaf, partly by means of elapsers, fourteen in number, which are situated in the under side of the abdomen; in addition to these there are six articulated legs. Except when crawling or feeding

these organs are invisible, being concealed by the body, and its slime or jelly. . . . During the greater part of their existence these slug-worms seem quite destitute of that rambling propensity which is commonly observable in the larvæ of Lepidoptera; indeed, in them rambling would be useless, since the upper cuticle and the parenchyma of the leaf, which constitute their principal food, are always within reach without the trouble of moving. These they consume in a very methodical manner, leaving the lower cuticle entire; this very soon dies, withers, and turns brown, making the whole tree look as though covered with dead leaves." After four or five changes of skin the slug reaches maturity, and "at the last change it loses the jelly-like surface, and appears in a neat yellow skin without any viscosity. This occurs nearly a month after the escape from the eggshell. The head and segmental divisions are now quite as perceptible as in any other species of saw-fly. Henceforward it eats no more, but crawls down the trunk of the tree and buries itself in the earth; at the depth of 3 or 4 inches each forms a neat little oval cell in which to undergo its final changes to a chrysalis and perfect fly. This cell is formed of earth, lined and intermixed with liquid glue secreted in the stomach."

The species is checked in its increase by parasitic enemies of the Hymenopterous sorts, of which nothing very definite is known. Of remedies applied by man the only effective one seems to be powdered hellebore, though sand, ashes, and lime have been perseveringly tried. Our American friends will do things in their own way, and the approved method of administering hellebore to this pertinacious slug is to raise a kind of platform; from this the mixture of hellebore and water is thrown downwards on the affected branches from the rose of a watering-pot. The dose is given at different times, as it serves to kill the fly as well as the slug. Some varieties of the Pear suffer more than others. The proportion of hellebore employed is 1 oz. to one and a half or two gallons of water.

#### NEW BOOK.

*The Rose Garden.* By WILLIAM PAUL. Fifth Edition.  
London: Kent & Co.

This is a new, an enlarged, and a very handsome edition of a work has been many years before the public, and which has become a guide-book to the Rose-cultivators of the present generation. In its present form the work forms a handsome imperial octavo volume of 324 pages, printed on excellent paper, and illustrated with fifteen life-size coloured portraits of some of the finest varieties, and numerous woodcuts. Some of the coloured portraits are beautiful specimens of modern chromolithography, and so beautifully are they executed it is difficult to detect that they are not water colours of the highest artistic flower-painting. Those of Firebrand, Louis Van Houtte, Madame La Baronne de Rothschild, St. George, Madame Levet (very beautiful), and Marie Van Houtte are those which please us best, though all are good.

Of the letterpress we need say nothing; Mr. Paul is so well acquainted with his subject, and is so experienced an author, that such a work coming from his hands comes with authority.

#### CHERRIES IN SWITZERLAND—FRUIT-CULTURE SCHOOLING.

"C. P. P.'s" description of his journey from Lucerne to Paris contains statements which, if not slightly corrected, might convey erroneous impressions as to that part of the Continent. Having been resident in those districts for many years I am able to supplement his notes.

The traveller admires the immense quantities of Cherries, and is very much surprised that the birds have not eaten them. "C. P. P." comes, therefore, to the conclusion that there are no small birds in that country. Your correspondent says, "But we miss abroad our British songsters and robins, and that most useful of all birds the starling." My own observations, however, point quite in a different direction, as not only are the songsters found in Britain represented there, but robins and, as "C. P. P." truly says, that most useful bird the starling, are also found in considerable numbers.

The protection of useful birds is very rigorously carried out in Switzerland and its adjacent countries, and anyone found in the possession of a blackbird or its kindred would speedily be mulcted in a severe fine, the informer receiving half the amount.

But "C. P. P." mentions the birds in relation to the destruction they would cause to the Cherries. It must be borne in mind, however, that were birds to come in such numbers so as, like the arrows of Xerxes' army, to obscure the sun, they would cause no perceptible difference, so enormous are the crops of that luscious fruit produced.

Your correspondent says he believes that that famous liqueur "Kirshenwasser" is produced from the kernels only. In that he is misinformed, as the liqueur is produced from the whole fruit. In fact, several owners of distilleries told me that unless the crops were very scanty they would prefer the kernels to be cast aside.

There may be some idea formed of the extent of the culture, when fine luscious fruit may be bought at one halfpenny per pound. But this holds good with other kinds of fruit, such as Apples, Plums (Quelohen), &c., thousands of tons of the former being annually exported to Northern Germany.

But how is it, it may be asked, that we do not attempt the culture of those fruits on the same scale? So long as tenants are not reimbursed for the improvements carried out on their farms, so long will fruit cultivation on an extensive scale remain in its infancy.

In the countries referred to the land is divided into small holdings, each occupier being the owner; consequently he is constantly endeavouring to make the most of his plot. All his land, whether pasture or under tillage, is planted with fruit trees, tall standards, so as to admit the oxen with the plough to pass beneath them. You may see the peasant trudging home with, perhaps, a dozen of young trees on his back to fill up any vacancies, or to stock a fresh piece of land he has acquired. Lanes and highways in this country, dotted here and there with crooked Elms, are there advantageously lined with Walnuts, Apples, Cherries, &c.

The peasants acquire the love for arboriculture while yet at school. A plot of ground planted with an assortment of fruit trees being generally at the disposal of the schoolmaster and his pupils, he will give them lessons on grafting and budding; explain to them the relative merits of the different varieties, and thus implant knowledge into the young minds which generally bears fruit in after-life. On one occasion I saw half a dozen youngsters clambering up a wild Cherry tree which had previously been looped, and under the direction of the long-coated spectacled wielder of the rod; and they commenced grafting the tree with some new varieties that had been received.

If some such system were adopted in the schools of our agricultural districts it would diffuse practical knowledge among our rising generation, the importance and the results of which could with difficulty be estimated.—A. W., *Heighington*.

#### FROST IN IRELAND—WORMS IN STRAWBERRY POTS.

We had frosts here on seven nights during October—viz., 10th, 4°; 12th, 3°; 13th, 1°; 14th, 4°; 15th, 1°; 17th, 1°; and on the 23rd the mercury fell to the freezing point. The highest minimum on the ground was on the 7th—viz., 47°. Rain fell on twenty-two days out of the thirty-one, the last week being particularly heavy, the quantity being 5.002, or a little over 5 inches. The result is the trees are being fast denuded of their foliage, and a wintry aspect put on. I may mention that the common Beech trees have been singularly beautiful the past three weeks; the coloration of their leaves in their decay has been crimson and gold, giving the landscape a charming effect. Bedding plants are mostly cut-up, but Dahlias are tolerably good as yet where sheltered, but the continual rain is making sad havoc amongst them. One row of eighty plants of Ruby Queen is particularly full and bright; they are screened on the north side by a close hedge.

In answer to "J. H." (page 377 of our Journal), when I forced Strawberries extensively I always contrived to put a good handful of soot over the drainage when putting the plants into their fruiting pots, and, like Mr. Douglas, I found it a good preventive of worms entering the pots, as well as a fine stimulant when the roots reached it, which the glossy foliage soon told. If worms were troublesome, which will sometimes occur if the soil is not carefully picked over when preparing for potting, the best treatment is to turn the plants out of the pots and pick the worms out; or to mix a little lime and soot water, not too strong, and when it has become clear give a watering with the liquid; the worms will rise to the surface,

and can be easily removed.—Geo. CURD, *Belvedere, Co. Westmeath.*

## CHRYSANTHEMUMS

AT THE ALEXANDRA PALACE.

Messrs. W. CUTBUSH & SONS, Highgate, have provided the display in the Alexandra Palace; the plants are arranged for conservatory effect, no attempt at producing grand blooms and gigantic plants having been made. The plants are arranged on an elevated platform down the centre of the great hall, about 120 feet in length, containing five tiers of plants. Of this bank of flowers Chrysanthemums are the staple; amongst which are intermixed hardy Palms, Solanums, Retinosporas, Heaths, Euonymuses, &c., with a few large Musas, green Dracenas, and Dicksonias. The display is very effective and worthy inspection, and the bright colouring of the hall itself is for once subdued by the brighter colours of the Chrysanthemums.

The plants generally are not large, but are admirable examples of conservatory decorative plants, the Pompons especially being dense and well bloomed; and many plants of the large-flowering section are not only dwarf and floriferous, but most of the blooms are of good size and shape. The display includes all the best varieties, and it is noticeable that sorts which have been favourites for twenty years are favourites still. Annie Salter presents a golden mass of compact blooms, stamping it as still good. Aureum Multiflorum is yet brighter and very effective. Princess of Teck, white and pink, is very fresh; and Princess of Wales and Empress of India show to advantage amongst the light-coloured flowers. Elaine, Felicity, and Mrs. G. Rundle are still more pure, and are indispensable in all collections. Jardin des Plantes and Gloria Mundi are very fine, and Mrs. Sharpe and Dr. Sharpe, with George Glennys, are worthy of special note. Most of these plants are in 6 and 7-inch pots, each having about fifty good blooms.

Amongst the best of the Pompons are Golden Aurora, Antonius, La Vogue, and Mr. Aste amongst the yellows; Andromeda, Mrs. Dix, Madame Fould, Madame Martha, and Marie Stuart (a lovely Anemone-flowered variety), and Andromeda rosea are the best of the light and rose colours; and amongst the dark colours are Brilliant, rich crimson; Dick Turpin, very gay; and Miss Julia, a chastely-formed flower, each of the chestnut petals being tinged with gold.

Cut blooms of all the best varieties are included in the display, and which, with fading plants, are renewed from Mr. Cutbush's reserve stores at Highgate. This display is as creditable to the old Highgate firm as the plants are worthy of the splendid hall in which they are arranged.

The display is to be continued until the 27th inst.

AT THE PINE APPLE NURSERY, MAIDA VALE.

We visited this nursery with "great expectations," and we are free to say that they have been amply fulfilled; for the arrangement of the plants in the great conservatory is exceedingly imposing, and the collection has a just claim to be considered as one of the finest exhibitions of the year. It is not fine, however, for a few highly-perfected and massive blooms, neither is it in any way remarkable for trained symmetrical plants, but it is yet a great show of Chrysanthemums.

The plants are grown in the most natural manner, and are as vigorous as good culture could make them, and as floriferous as healthy plants can be. There has been no thinning of the buds and no bending of the branches, but each plant has followed its own habit, and has loaded itself with all the blooms that it was capable of producing. The plants, of which there are about a thousand, are mostly on single stems and afterwards branched into large heads, vary from 5 to 8 feet in height, and the conservatory is one great mass of glowing, soft, and brilliant colours. The health and exuberant foliage of the plants is also very noteworthy—indeed they resemble in this respect plants which had an unlimited range in trenched soil rather than restricted larders of 9 and 10-inch pots.

Amongst the most noticeable varieties of this great display are Aimée Ferrière, silvery white tipped with rose, and very lovely; George Glennys; Prince of Wales, extra fine; Prince Albert, rich crimson; Lady Talfour, Golden John Salter, Jardin des Plantes, Fingal (very good), Sam Weller, White Venus, Eve, White Globe, Ariadne, Empress of India, and Lady Hardinge. Little Harry and Aureum Multiflorum afford proof of their usefulness, and Progne is not only distinct by its rich colour, but is deliciously scented, rivalling almost the scent of Violets. Whether this is an accidental circumstance

we are unable to say, but certain it is that the perfume is remarkable and decided. These are a few of the best of the large-flowered varieties. Noticeable in the Japanese section are Elaine, Fair Maid of Guernsey, Gloire de Toulouse (very fine), and Garnet. Amongst the Pompons the best are Acquisition, Prince of Anemones, Princess Thyra, Lady Margaret, Miss Julia, Aurora Borealis, Bob, and Julie Lagravère. The last-named is not strictly a Pompon, but by its free-blooming character and rich colour it must be considered one of the most useful for decorative purposes and for affording a great supply of cut blooms. This gay collection is now at its best, and is worthy a visit by all who can appreciate this fine autumn flower when grown in a natural manner and without string and stakes, the plants at the same time possessing great vigour and an unusual multiplicity of bloom.

The other collections of plants in this nursery are in excellent health, notably the Azaleas and show Pelargoniums, which are well and extensively grown. Heaths and ornamental-foliaged plants are also as clean and healthy as we expect to find them in a first-class establishment.

## LARGE PEARS.

We have from time to time read in the newspapers surprising accounts of the enormous size Pears and Apples have reached in California and other favoured places in the United States, but I had no idea that we possessed in England either a climate or a soil sufficiently fertile to produce Pears rivaling the fruits of our brother Jonathan. A few days ago I received from Carmarthenshire a box of specimen Pears of such unusual size and beauty, that I think they are worthy of being noticed in the pages of our Journal.

Easter Beurré, 1 lb. 1 oz.; Beurré Superfin, 1 lb. ½ oz.; Durandean, 14½ ozs.; Beurré d'Anjou, 12 ozs.; Marie Louise, 12½ ozs.; Winter Nelis, 10½ ozs.; Gansel's Seckle, 8 ozs.; Zephirin Grégoire, 6½ ozs.; Doyenné du Comice, 1 lb. 6½ ozs.

This last magnificent specimen measured 13½ inches every way. These Pear trees were not delicately nurtured under glass in an orchard house and fed with stimulants, but they grew in the open air, and carried full crops of fruit. The Marie Louise last year produced upwards of 640 fruit, and has yielded another very large crop this year.—C. M., *Vicarage, Gargrave.*

## OUR BORDER FLOWERS—STATICES.

An extensive order of ornamental border plants are the Statice. Some of them are natives of Britain. Under favourable circumstances in the vicinity of some of our large rivers and seacoasts they are very attractive. They are frequently met with in what are termed salt marshes, and are known to many as "Sea Lavender." If not presenting to us the gayest of colours, there is a grace and beauty in many of their habits and flowers that is only to be seen in their own family. They may be planted either on the rockery or in the border. They are moisture-loving plants, but should not suffer from continual saturation. They will grow well in a mixture of good loam, peat, leaf mould, and sand; and are increased by seed and division. When established the plants should be disturbed as little as possible. They are useful where cut flowers are in demand, lasting for a length of time after being cut. Some of them when carefully dried retain much of their original beauty, and are useful for decoration in winter, when flowers are not over-plentiful.

Statice Limonium is one of the best herbaceous plants we have in cultivation. It is useful as a pot plant, and indispensable for exhibition purposes. It lasts a long time in bloom, and ought to be in all gardens. *S. latifolia* is said to be a variety of the above; it is a fine border plant. *S. bellidifolia*, or known by some as *S. globularisifolia*, is a compact-growing kind, adapted alike for the rockery or border. *S. nana* is of neat dwarf habit, and is a good rock plant. *S. incana alba* is a charming plant, and should have a place on all rockeries and borders. There are also *S. alpina* and *S. Gmelini*, and a host of others that need only to be seen to be appreciated. *S. tatarica* is of compact habit, and is one of the best of the family; it is desirable on account of its late-blooming properties. *S. binervosa* is also a useful border plant, but does not remove well, except small young plants are chosen. *Statice ararati*, or *Acantholimon glumaceum*, is worthy of special notice. This species cannot endure much wet, and should have thorough drainage; it should have a sunny situation on

the rockery, for it is not safe to leave it in the ordinary border through the winter. It is a spring-blooming plant of compact habit, and its lovely-coloured blooms claim for it a first place in the spring garden.—*VERITAS.*

### COLE ORTON HALL, No. 1.

THE SEAT OF SIR GEORGE H. BEAUMONT, BART.

It was during a "rift in the clouds" in the period of the midland deluge that I paid a flying visit to this memorable place—memorable alike for its historical associations, its intrinsic beauty, its rocks, dells, Conifers, its monumental en-tablatures, and last, but not least, for the successful practice in fruit, especially Grape production, which has for a period of thirty years been carried on by Mr. Henderson.

The first syllable of Cole Orton is a corruption of "coal," applied to the district on account of the coal pits around, and Orton is a contraction of Overton. It is mentioned as early as the time of Henry III., and after various descents passed by marriage in 1426 to the Beaumont family. After various forfeitures during the war of the "Two Roses" it finally was resumed by the Beaumonts. It was first imparked by one of the Maurewards in the fourteenth century, but the old park was soon destroyed by the establishment of coal mines. The old hall, erected in 1600 by Sir Henry and Lady Beaumont, was destroyed during the civil wars. The present residence, Cole Orton Hall, was commenced building in 1804 by Sir G. H. Beaumont, and finished in 1808.

The mansion is in the French and Gothic style of architecture, and is rich in works of art by the old masters, including many from the easel of the first Sir George Beaumont; it also contains some of the masterpieces of Sir David Wilkie. The grounds are not only beautiful in their arrangement and by the many fine views they command through vistas of foliage, but they teem with interest from their connection with incidents of names renowned in science and literature. At every turn the visitor is reminded of the classic associations of the place by busts, and urns, and rock-engraved poetry. At one place is the Cedar which Wordsworth planted and made famous, at another is the ponderous stone where Mrs. Siddons, Coleridge, and Wordsworth met and held "congenial converse." There is the urn and avenue in memory of Sir Joshua Reynolds, and the "niche in the rock" cut by Wordsworth and Mrs. Wordsworth, and in which a portion of *Ivanhoe* was written by Sir Walter Scott. Having shadowed forth the nature of the place I will attempt to detail some of its more prominent features.

The surroundings of the mansion are heavily wooded, many of the trees where isolated being remarkably fine, while thousands are so closely massed as not to show their individual proportions. They have mostly an undergrowth of evergreens, and it is worthy of note how healthy the Yews are on which the sun can never shine during the summer months, and which proves the value of this shrub for undergrowth. But contiguous to the mansion are open lawns of considerable extent, and which contain many handsome specimens of deciduous trees and Conifers.

Wordsworth would appear to have been the chief adviser in the laying-out of these gardens and grounds, and at the time of their formation he dedicated to Lady Beaumont the following lines on the garden which he planted:—

"Lady! the songs of spring were in the grove  
While I was shaping beds for winter flowers;  
While I was planting green unfading bowers,  
And shrubs to hang upon the warm alcove  
And sheltering wall; and still as fancy wove  
The dream to Nature's blended powers  
I gave this paradise for winter hours—  
A labyrinth, lady, which your feet shall rove.  
Yes, when the sun of life more feebly shines,  
Becoming thoughts, I trust, of solemn gloom  
Or of high gladness you shall hither bring,  
And these perennial bowers and murmuring Pines  
Be gracious as the music and the bloom,  
And all the mighty ravishment of spring."

Thus did Wordsworth write of this winter garden, comprising about 3 acres, every tree of which passed through his own hands, and which are still cherished in their wild stateliness. The "labyrinth" has gone, and the "winter flowers" are overgrown by the "green unfading bowers," save a few old spring herbaceous plants and bulbs which fringe the shrubby beds; but the "perennial Pines" are vigorous, almost majestic, and are living memorials of the poet's love and labours.

The garden, which is known as "Wordsworth's garden,"

is charmingly diversified in character. It contains a romantic dell, bounded on one side by rugged rocks, overshadowed by a gigantic Wych Elm, whose gaunt arms stretch over immense space, and its twisted tortuous roots leap over the sides of the rock, affixing themselves in the crevices below. At the base are Ferns revelling in wild luxuriance. Wending our way under the "unfading bowers" we come to still more rugged Ivy-clad rocks of venerable aspect, and near them a fine marble vase from Pompeii. We pass on—the very atmosphere redolent of romance and poetry—and here is the Grotto, just such a place as one might fancy "where rural fays and fairies dwell," and here we find the niche in the rock before alluded to. It is squarely and cleanly hewn, of sufficient size to form a comfortable resting place, and in which the author of *Waverley* reclined and gave play to his rich imagination. Close by, inscribed on a tablet by Wordsworth himself, are the following lines:—

"Oft is the medal faithful to its trust  
When temples, columns, towers are laid in dust;  
And 'tis a common ordinance of fate  
That things obscure and small outlive the great.  
Hence when you mansion and the flowery trim  
Of this fair garden and its alleys dim,  
And all its stately trees are passed away,  
This little niche, unconscious of decay,  
Perchance may still survive. And be it known  
That it was scooped within the living stone,  
Not by the sluggish and ungrateful pains  
Of labourer plodding for his daily gains;  
But by an industry that wrought in love,  
With help from female hands which proudly strove  
To aid the work, what time these walks and bowers  
Were shaped to cheer dark winter's lonely hours."

Near to this hermit-like retreat we pause to glance at the ruins of an Ivy-covered cottage, reached by an ascent of rude steps. This once formed part of the village of Cole Orton, and was the scene of Sir David Wilkie's famous painting of "An Old Woman Knitting." The old ruin is quite ornamental, and is in admirable keeping with the wild solitude of this part of the grounds. Passing through a stone arch we come to an open lawn, and find many specimens of Conifers of perfect form and in great luxuriance. These, on the smooth lawn and thinly planted, show their graceful outlines and proportion to great perfection. Of *Pinus Morinda* there is a grand example, and *Wellingtonias* and *Deodars* are to be classed amongst the finest in the country. *Thuja gigantea* is 25 feet in height, and *Picea nobilis* is considerably taller, and clothed in its beautiful silvery garb. We pass a grand specimen of *Abies orientalis*, quite 30 feet in height, rich in colour and dense; and *Picea lasiocarpa* is of immense size and vigorous. We hurry past many others, but are compelled to pause at *Abies Douglasii*. This handsome specimen was planted by Mr. Henderson when it was only 15 inches high; it is now 50 feet in height, and has long had crops of splendid cones. *Picea nobilis* has also had cones; it is a fine pyramid, and was itself raised from English seed. *Pinus grandis* is too tall to guess at, and we had no time to measure its height, but it is 30 yards round as it sweeps the lawn. Of *Cedrus deodara robusta* there is a noble specimen, quite distinct from the original type. *Retinosporas* are 8 to 10 feet in height, and *Cryptomerias*, *Cupressuses*, *Araucarias*, &c., four times those heights. The *Araucarias* are exceedingly fine and varied in habit. From some of them seed is regularly saved. In this pinetum are many valuable specimens which I cannot notice, and which are in remarkable health and condition.

But we have not quite done with trees, for on the lawn, in more immediate vicinity of the mansion, we come to examples which compel a momentary glance.

Near the church (an appropriate site) is a fine *Deodar*, which the inscription states was planted by Archbishop Howley on July 30th, 1846, his Grace being then in his 81st year. The church is within the grounds on the margin of the lawn. "Do you care for a church?" asked my guide. Do I care for a church! (it will be an evil day for England when churches are not cared for, but there is not much fear of that being the case), I do care, and more than care, for a church, so I am permitted to enter. I am tempted to dwell on those who have found solace here, but refrain; but I am pleased to see the church is cared for with a loving and a reasonable care. There are a few flowers in it—"Everlastings"—and old family monuments, and "breathings in stone" of Wordsworth. On one of the monuments I note that Sir Henry and Lady Beaumont died in 1807 and 1808 respectively, and another tells us that Sir George Beaumont, the great painter, died February 7th, 1827. The church is an integral part of Cole

Orton, and I am sure the mention of it will be welcomed in these columns.

We leave it, and note next another memorial tree, a magnificent Cedar of Lebanon, planted by Wordsworth and Sir G. H. Beaumont. This tree is near to the mansion, and is a specimen to be proud of. It is of great size and in robust health, and has been sustained by "Nature's kindest powers," and protected by the loving care which the poet invoked in the following lines:—

"The embow'ring Rose, the Asacia, and the Pine  
Will not unwillingly their place resign  
If but the Cedar thrive who near them stands,  
Planted by Beaumont's and by Wordsworth's hands.  
One used the silent art with studious pains,  
These groves have heard the other's pensive strains;  
Devoted thus their spirits did unite  
By interchange of knowledge and delight.  
May Nature's kindest powers sustain the tree,  
And love protect it from all injury;

And when its potent branches wide out-throw  
Darken the brow of this memorial stone,  
Here may some painter sit in future days,  
Some future poet meditate his lays,  
Not mindless of that distant age renowned  
When inspiration hovered o'er this ground,  
The haunt of him who sang how spear and shield  
In civil conflict met on Bosworth field;  
And of that famous youth full soon removed  
From earth, perhaps by Shakespeare self-approved,  
Fletcher's associate, Jonson's friend beloved."

This fine tree not only "darkens the brow of the memorial stone," but overhangs a portion of the mansion, and in a few more years may raise a regret that it was planted on a site where it would not have full scope to expand and show its noble form to advantage.

Near to the terrace walk by the side of the mansion are also other encroaching trees—a row of *Arancarias*. These stately specimens, I think fifteen in number, have a bold appearance in contrast to the light stone of the structure, and are remark-

Fig. 96.—THE FLOWER GARDEN AT COLE ORTON HALL.

ably effective, but have been planted fully too near the walk, or, like Wordsworth's Cedar, they have exceeded the bounds anticipated.

We now cross the lawn for a glance at the flower garden, a view of which is shown in the engraving. Our descent is by a flight of steps. The garden as seen from the terrace is exceedingly fine. The beds are thinly placed and with their masses of flowers, compact Conifers, and fine sweep of lawn—with the massive boundary of *Rhododendrons* on one side and shrubbery on the other, with the rosery as the most distant boundary and the grand views beyond, a combination of fine features is provided such as can seldom be seen at a glance. This garden is just an acre in extent, and is truly beautiful. The boundary of *Roses* demand a note of explanation. The boundary is a sunk fence, and on the slope, which is considerable, the *Roses* are planted. They are on standards, and are planted in about ten rows of nearly 100 yards each. They are of heights sufficient to show distinctly above the terrace wall, forming one glorious bank of blooms which must be seen to be appreciated. But how easy the idea is of being carried out by others! How many are the sunk-fence boundaries to gardens which are destitute of beauty, and what grand banks of *Roses* they might be! *Roses* at Cole Orton are grown by thousands, being special favourites of Sir George H. Beaumont,

and who devotes to them much personal attention. They give undoubted evidence of skill in culture, and generally afford blooms until Christmas: in October they were showing almost as freely as in May.

I must postpone my further remarks on this fine garden, noticing, perhaps, a few more trees, a little more memorial poetry, and something about Grape and Pine Apple growing of a nature not commonly to be met with. It is gratifying to find that a place so fine as Cole Orton is in the care of an owner who not only sustains but increases its natural beauty, whose care it everywhere shadows, as it does the admitted skill of the gardener Mr. Henderson.—J. W.

#### A SEASHORE WEED ON GARDEN WALKS.

It is generally admitted that every garden has its favourite weed, as well as being more or less remarkable for producing one or more crops better than the rest. In some gardens the wild *Convolvulus* is very difficult to expel, in others it may be *Orowfoot*, or possibly some annual weed may persistently make its appearance; while there are two cultivated plants quite as difficult to eradicate as any native weed, and these are *Horseradish* and *Jerusalem Artichoke*, the first-named especially being very tenacious of life. Now and then we also

receive a fresh invasion from abroad or, it may be, a distant part of the country, and for a time the new comer runs riot everywhere. I have recently had an addition to our "weed list" which may be troublesome.
